- **CNS DEPRESSANT DRUGS** (e.g., **anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol**, etc.): May cause increased CNS or respiratory depression when used with opiate antidiarrheal agents
- **MONOAMINE OXIDASE INHIBITORS** (including **amitraz**, and possibly **selegiline**): Opiate antidiarrheal agents are contraindicated in human patients receiving monoamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors

Laboratory Considerations

- Plasma **amylase** and **lipase** values may be increased for up to 24 hours following administration of opiates.

Doses

■ DOGS:

- a) For acute colitis: 0.06 mg/kg, PO three times daily (DeNovo 1988)
- b) For maldigestion; malabsorption; antidiarrheal: 0.05–0.06 mg/kg PO two to three times daily (Chiapella 1988), (Johnson 1984)
- c) As an antidiarrheal: 0.05–0.06 mg/kg PO q12h (Willard 2003a)

■ CATS:

Note: Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

For maldigestion, malabsorption, anti-diarrheal:

- a) 0.05–0.06 mg/kg PO two to three times daily (Chiapella 1988), (Johnson 1984)

■ CATTLE:

- a) Calves: 15–30 mL PO (Cornell 1985)

■ HORSES:

- a) Foals: 15–30 mL PO; Adults: 15–60 mL PO (Cornell 1985)

Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea
- CNS effects if using high dosages

Client Information

- If diarrhea persists or animal appears listless or develops a high fever, contact veterinarian.

Chemistry/Synonyms

Paregoric contains 2 mg of the equivalent of anhydrous morphine (usually as powdered opium or opium tincture) per 5 mL. Also included (per 5 mL) is 0.02 mL anise oil, 0.2 mL glycerin, 20 mg benzoic acid, 20 mg camphor, and a sufficient quantity of diluted alcohol to make a total of 5 mL. Paregoric should not be confused with opium tincture (tincture of opium) which contains 50 mg of anhydrous morphine equivalent per 5 mL.

Paregoric is also known as camphorated tincture of opium.

Storage/Stability

Paregoric should be stored in tight, light-resistant containers. Avoid exposure to excessive heat or direct exposure to sunlight.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Paregoric (camphorated tincture of opium): 2 mg of morphine equiv. per 5 mL; 45% alcohol in 473 mL; generic; (Rx; C-III)

Note: Do not confuse with opium tincture which contains 25 times more morphine per mL than paregoric.

PAROMOMYCIN SULFATE

(pair-oh-moe-my-sin) Humatin®

ORAL AMINOGLYCOSIDE ANTIPARASITIC

Prescriber Highlights

- Aminoglycoside used primarily as an alternative for PO treatment of cryptosporidiosis in small animals
- Not appreciably absorbed when dosed orally in humans & dogs
- Some state that the drug is contraindicated in cats secondary to toxicity
- Adverse effects are usually limited to GI effects (N,V,D); cats may be susceptible to renal & ophthalmic toxicity
- Use with caution in patients with intestinal ulceration

Uses/Indications

Paromomycin may be useful as a secondary treatment for cryptosporidiosis in dogs and cats. It has also been used topically to treat cutaneous Leishmaniasis. In humans, it has been used as an alternative treatment for giardiasis, *Dientamoeba fragilis*, and hepatic coma.

Pharmacology/Actions

Paromomycin has an antimicrobial spectrum of activity similar to neomycin, but its primary therapeutic uses are for the treatment of protozoa, including *Leishmania* spp., *Entamoeba histolytica*, and *Cryptosporidium* spp. It also has activity against a variety of tapeworms, but there are better choices available for clinical use.

Pharmacokinetics

Like neomycin, paromomycin is very poorly absorbed when given orally. Potentially systemic toxicity (nephrotoxicity, ototoxicity, pancreatitis) could occur if used in patients with significant ulcerative intestinal lesions or for a prolonged period at high dosages.

Contraindications/Precautions/Warnings

Paromomycin is contraindicated in patients with known hypersensitivity to the drug, ileus or intestinal obstruction, and GI ulceration.

Use with caution in cats. Because of potential toxicity, some clinicians recommend not using the drug in this species.

Do not use in animals with blood in the stool as this may signal that the drug could be absorbed and cause nephrotoxicity.

Adverse Effects

Gastrointestinal effects (nausea, inappetence, vomiting, diarrhea) are the most likely adverse effects to be noted with therapy. Because paromomycin can affect gut flora, nonsusceptible bacterial or fungal overgrowths are a possibility. In patients with significant gut ulceration, paromomycin may be absorbed systemically with resultant nephrotoxicity, ototoxicity, or pancreatitis.

Use in cats has been associated with renal dysfunction and blindness.

Reproductive/Nursing Safety

Because minimal amounts are absorbed when administered orally, paromomycin should be safe to use during pregnancy. It should not be used parenterally during pregnancy.

When used orally, paromomycin should be safe to use during lactation.

Overdosage/Acute Toxicity

Because paromomycin is not absorbed orally, acute overdose adverse effects should be limited to gastrointestinal distress in patients with an intact GI system. Chronic overdoses may lead to systemic toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving paromomycin and may be of significance in veterinary patients:

- **DIGOXIN:** Paromomycin may reduce digoxin absorption
- **METHOTREXATE:** Paromomycin may reduce methotrexate absorption

Laboratory Considerations

None were noted.

Doses**■ DOGS:**

For treatment of cryptosporidiosis:

- a) 125–165 mg/kg PO twice daily for 5 days (Blagburn 2003a)
- b) 150 mg/kg PO once a day for 5 days (Tams 2003c)

■ CATS:

For treatment of cryptosporidiosis: **Note:** Higher dosages of paromomycin have caused renal toxicity and/or blindness in some treated cats. Consider using an alternate treatment first

(e.g., azithromycin) or paromomycin at an initially reduced dosage level.

- a) 125–165 mg/kg PO twice daily for 5 days. (Blagburn 2003a)
- b) 150 mg/kg PO once a day for 5 days. (Tams 2003c)

■ REPTILES:

For treatment of cryptosporidiosis: 300–800 mg/kg PO q24–48h for 7–14 days or as needed (de la Navarre 2003b)

Monitoring

- Efficacy
- GI adverse effects
- If used in cats, monitor renal function

Client Information

- Unless otherwise instructed, give with food.

Chemistry/Synonyms

An aminoglycoside antibiotic, paromomycin sulfate occurs as an odorless, creamy white to light yellow, hygroscopic, amorphous powder having a saline taste. Paromomycin is very soluble in water (>1 g/mL).

Paromomycin may also be known as: aminosidin sulphate, aminosidine sulphate, catenulin sulphate, crestomycin sulphate; estomycin sulphate, hydroxymycin sulphate, monomycin A sulphate, neomycin E sulphate, paucimycin sulphate, *Gabbromicina*®, *Gabbroral*®, *Gabbroral*®, *Humagel*®, *Humatin*®, *Kaman*®, and *Sinosid*®.

Storage/Stability

Paromomycin capsules should be stored at room temperature (15–30°C; 59–86°F) in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Paromomycin Sulfate Capsules: 250 mg (of paromomycin); *Humatin*® (Parke-Davis); (Rx)

PAROXETINE HCL

(pah-rox-a-teen) Paxil®

SELECTIVE SEROTONIN REUPTAKE INHIBITOR
(SSRI) ANTIDEPRESSANT

Prescriber Highlights

- Selective serotonin reuptake inhibitor antidepressant related to fluoxetine used in dogs & cats for variety of behavior disorders
- Contraindications: Patients with known hypersensitivity or receiving monoamine oxidase inhibitors
- Caution: Patients with severe cardiac, renal or hepatic disease. Dosages may need to be reduced in patients with severe renal, or hepatic impairment
- Adverse effect profile is not well established; potentially in DOGS: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Aggressive behavior in previously unaggressive dogs possible. CATS: May exhibit behavior changes (anxiety, irritability, sleep disturbances), anorexia, constipation & changes in elimination patterns

Uses/Indications

Paroxetine may be beneficial for the treatment of canine aggression, and stereotypic or other obsessive-compulsive behaviors. It has been used occasionally in cats as well.

Pharmacology/Actions

Paroxetine is a highly selective inhibitor of the reuptake of serotonin in the CNS, thus potentiating the pharmacologic activity of serotonin. Paroxetine apparently has little effect on other neurotransmitters (e.g., dopamine or norepinephrine).

Pharmacokinetics

No veterinary data was located. In humans, paroxetine is slowly, but nearly completely, absorbed from the GI tract. Because of a relatively high first pass-effect, relatively small amounts reach the systemic circulation unchanged. Food does not impair absorption.

The drug is about 95% bound to plasma proteins. Paroxetine is extensively metabolized, probably in the liver. Half-life in humans ranges from 7–65 hours and averages about 24 hours.

Contraindications/Precautions/Warnings

Paroxetine is contraindicated in patients with known hypersensitivity to it or those receiving monoamine oxidase inhibitors (see Drug Interactions below). Use with caution in patients with seizure disorders, severe cardiac, hepatic, or renal disease. Dosages may need to be reduced in patients with severe hepatic or renal impairment.

Adverse Effects

In dogs, paroxetine can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously unaggressive dogs has been reported. SSRIs may also cause changes in blood glucose levels and potentially, reduce seizure threshold.

Paroxetine in cats can cause behavior changes (anxiety, irritability, sleep disturbances), anorexia, constipation and changes in elimination patterns.

Reproductive/Nursing Safety

Paroxetine's safety during pregnancy has not been established. Preliminary studies done in rats demonstrated no overt teratogenic effects. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

The drug is excreted into milk but at low levels; caution is advised in nursing patients.

Overdosage/Acute Toxicity

There is limited information available. Experience with overdoses in humans yields a mixed picture. While not as toxic as the tricyclic antidepressants, fatalities and significant morbidity have occurred after paroxetine overdoses.

There were 214 exposures to paroxetine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 187 were dogs with 19 showing clinical signs, 22 were cats with 4 showing clinical signs and the remaining 5 cases were birds of which 1 showed clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, ataxia, agitation, depression and hyperthermia. Common findings in cats recorded in decreasing frequency included anorexia, lethargy, adipsia, anuria and hypersalivation. Common findings in

birds recorded in decreasing frequency included anorexia, erratic behavior, head bobbing, lethargy and regurgitation.

In overdoses with small animals, it is recommended to err on the safe side and employ gut evacuation (if not contraindicated) and then treat supportively. Contact an animal poison control center for additional guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving paroxetine and may be of significance in veterinary patients:

- **BUSPIRONE:** Increased risk for serotonin syndrome
- **CIMETIDINE:** May increase paroxetine levels
- **CYPROHEPTADINE:** May decrease or reverse the effects of SSRIs
- **DIGOXIN:** Paroxetine (in humans) can decrease digoxin AUC by 15%
- **INSULIN:** May alter insulin requirements
- **ISONIAZID:** Increased risk for serotonin syndrome
- **MAO INHIBITORS** (including **amitraz** and potentially, **selegiline**): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing paroxetine and a 2 week washout period if first discontinuing the MAO inhibitor
- **PENTAZOCINE:** Serotonin syndrome-like adverse effects possible
- **PHENOBARBITAL:** May decrease paroxetine levels
- **PHENYTOIN:** Increased plasma levels of phenytoin possible; may decrease paroxetine levels
- **PROPRANOLOL, METOPROLOL:** Paroxetine may increase these beta-blockers' plasma levels and cause hypotension; atenolol may be safer to use if paroxetine required
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., **clomipramine**, **amitriptyline**): Paroxetine may increase TCA levels and may increase the risk for serotonin syndrome
- **THEOPHYLLINE:** Increased plasma levels of theophylline possible
- **WARFARIN:** Paroxetine may increase the risk for bleeding

Doses

■ DOGS:

For SSRI responsive behavior problems:

- a) For compulsive disorders: 1 mg/kg (up to 3 mg/kg) PO once daily (q24h) (Landsberg 2004)
- b) For storm phobias: 1 mg/kg PO once daily for 3–5 months, then taper (Crowell-Davis 2003c)
- c) For adjunctive treatment of phobias, fears, and anxieties: 0.5–1 mg/kg PO once daily (Moffat 2007a)

■ CATS:

For SSRI responsive behavior problems:

- a) 2.5–5 mg (total dose) per cat PO once daily (Reisner and Houpt 2000)
- b) For compulsive disorders: 0.5–1 mg/kg PO once daily (q24h) (Landsberg 2004)
- c) For interspecies aggression: 0.5–1 mg/kg PO once daily (Crowell-Davis 2003b)
- d) For marking: 0.5–1 mg/kg PO once daily (Landsberg 2007), (Neilson 2007)
- e) For intercat aggression: 0.5–1 mg/kg PO once daily (Moffat 2007b)

Monitoring

- Efficacy
- Adverse effects; including appetite (weight)

Client Information

- Keep medication out of reach of children and pets
- May cause GI effects (especially lack of appetite, constipation), behavior and sleep changes; if these become issues, contact veterinarian

Chemistry/Synonyms

A selective serotonin reuptake inhibitor (SSRI) antidepressant, paroxetine HCl occurs as an off-white, odorless powder. It has a solubility in water of 5.4 mg/mL and a pKa of 9.9.

Paroxetine may also be known as: BRL-29060, FG-7051, and *Paxil*®.

Storage/Stability

Paroxetine oral tablets should be stored at 15–30°C. The oral suspension should be stored below 25°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Paroxetine Tablets: 10 mg, 20 mg, 30 mg & 40 mg; *Paxil*® (GlaxoSmithKline); generic; (Rx)

Paroxetine Tablets Controlled-release: 12.5 mg, 25 mg and 37.5 mg; *Paxil*® CR (GlaxoSmithKline); (Rx)

Paroxetine Oral Suspension: 2 mg/mL in 250 mL btls (orange flavored); *Paxil*® (GlaxoSmithKline); (Rx)

PEG 3550 Products—see **Saline Cathartics**

PENICILLAMINE

(pen-i-sill-a-meen) Depen®, Cuprimine®

ANTIDOTE; CHELATING AGENT

Prescriber Highlights

- ▶ Chelating agent used primarily for copper-storage hepatopathies (dogs). May be considered for lead poisoning or cystine urolithiasis
- ▶ Contraindications: History of penicillamine-related blood dyscrasias
- ▶ Adverse Effects: Nausea, vomiting, & depression. Rarely: Fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy
- ▶ Potentially teratogenic
- ▶ Preferably given on an empty stomach

Uses/Indications

Penicillamine is used primarily for its chelating ability in veterinary medicine. It is the drug of choice for Copper storage-associated hepatopathies in dogs, and may be used for the long-term oral treatment of lead poisoning or in cystine urolithiasis.

Although the drug may be of benefit in chronic hepatitis, doses necessary for effective treatment may be too high to be tolerated.

Pharmacology/Actions

Penicillamine chelates a variety of metals, including copper, lead, iron, and mercury, forming stable water soluble complexes that are excreted by the kidneys.

Penicillamine combines chemically with cystine to form a stable, soluble complex that can be readily excreted.

Penicillamine has antirheumatic activity. The exact mechanisms for this action are not understood, but the drug apparently improves lymphocyte function, decreases IgM rheumatoid factor and immune complexes in serum and synovial fluid.

Penicillamine possesses antifibrotic activity via inhibition of collagen crosslinking thereby causing collagen to be more susceptible to degradation.

Although penicillamine is a degradation product of penicillins, it has no antimicrobial activity.

Pharmacokinetics

In humans, penicillamine is well absorbed after oral administration and peak serum levels occur about one hour after dosing. The drug apparently crosses the placenta but, otherwise, little information is known about its distribution. Penicillamine that is not complexed with either a metal or cystine is thought to be metabolized by the liver and excreted in the urine and feces.

Contraindications/Precautions/Warnings

Penicillamine is contraindicated in patients with a history of penicillamine-related blood dyscrasias.

Adverse Effects

In dogs, the most prevalent adverse effects associated with penicillamine are nausea, vomiting, and depression. If vomiting is a problem, attempt to alleviate by giving smaller doses of the drug on a more frequent basis. Although food probably decreases the bioavailability of the drug, many clinicians recommend mixing the drug with food or giving at mealtimes if vomiting persists. Although thought infrequent or rare, fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy may occur.

Reproductive/Nursing Safety

Penicillamine has been associated with the development of birth defects in offspring of rats given 10 times the recommended dose. There are also some reports of human teratogenicity. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Lactation safety has not been established.

Overdosage/Acute Toxicity

No specific acute toxic dose has been established for penicillamine and toxic effects generally occur in patients taking the drug chronically. Any relationship of toxicity to dose is unclear; patients on small doses may develop toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillamine and may be of significance in veterinary patients:

- **4-AMINOQUINOLINE DRUGS** (e.g., **chloroquine**, **quinacrine**): Concomitant administration with these agents may increase the risks for severe dermatologic adverse effects
- **CATIONS, ORAL INCLUDING ZINC, IRON, CALCIUM, MAGNESIUM**: May decrease the effectiveness of penicillamine if given orally together

- **FOOD, ANTACIDS:** The amount of penicillamine absorbed from the GI tract may be reduced by the concurrent administration of food or antacids
- **GOLD COMPOUNDS:** May increase the risk of hematologic and/or renal adverse reactions
- **IMMUNOSUPPRESSANT DRUGS** (e.g., cyclophosphamide, azathioprine, but **not corticosteroids**): May increase the risk of hematologic and/or renal adverse reactions
- **PHENYLBUTAZONE:** May increase the risk of hematologic and/or renal adverse reactions

Laboratory Considerations

- When using **technetium Tc 99m gluceptate** to visualize the kidneys, penicillamine may chelate this agent and form a compound that is excreted via the hepatobiliary system resulting in gallbladder visualization that could confuse the results.

Doses

■ DOGS:

For copper-associated hepatopathy:

- a) 10–15 mg/kg PO q12h on an empty stomach. Do not give concurrently with any medication, including zinc or a vitamin-mineral supplement. (Jergens and Willard 2000)
- b) 10–15 mg/kg PO two times a day. If vomiting ensues the dose is split and given at mealtime or with a small portion of meat. (Center 2002)
- c) 10–15 mg/kg PO two times a day 30 minutes prior to food. Start low and increase. (Webb 2007b)

For cystine urolithiasis:

- a) 15 mg/kg; PO twice daily. If nausea and vomiting occur, mix with food or give at mealtime. Some dogs may need to have the dosage slowly increased to full dose in order to tolerate the drug. (Osborne, Hoppe, and O'Brien 1989)
- b) 15 mg/kg; PO twice daily with food (Lage, Polzin, and Zenoble 1988)

For lead poisoning:

- a) After initial therapy regimen with CaEDTA and if continued therapy is desired at home, may give penicillamine at 110 mg/kg/day, PO divided q6–8h for 1–2 weeks. If vomiting, depression, and anorexia occur, may reduce dose to 33–55 mg/kg/day divided q6–8h, which should be better tolerated. (Mount 1989)
- b) As an alternate or adjunct to CaEDTA: 110 mg/kg/day divided q6–8h PO 30 minutes before feeding for 1–2 weeks. If vomiting a problem may premedicate with dimenhydrinate (2–4 mg/kg PO). Alternatively, may give 33–55 mg/kg/day divided as above. Dissolving medication in juice may facilitate administration. (Nicholson 2000)

■ CATS:

For lead poisoning:

- a) After initial therapy with CaEDTA and if blood lead is greater than 0.2 ppm at 3–4 weeks post-treatment, may repeat CaEDTA or give penicillamine at 125 mg q12h PO for 5 days. (Reid and Oehme 1989)

■ SMALL RUMINANTS:

Note: When used in food animals, FARAD recommends a minimum milk withdrawal time of 3 days after the last treatment and a 21-day preslaughter withdrawal. (Haskell, Payne et al. 2005)

For copper toxicity:

- a) 52 mg/kg daily for 6 days is sometimes successful (Reilly 2004)

■ BIRDS:

For adjunctive treatment of lead poisoning:

- a) 55 mg/kg PO q12h for 1–2 weeks. It has been suggested that combining CaEDTA and penicillamine for several days until symptoms dissipate followed by a 3–6 week treatment with penicillamine as the best regimen for lead toxicity. (Jones 2007a)

Monitoring

- Monitoring of penicillamine therapy is dependent upon the reason for its use; refer to the references in the Dose section above for further discussion on the diseases and associated monitoring of therapy.

Client Information

- This drug should preferably be given on an empty stomach, at least 30 minutes before feeding. If the animal develops problems with vomiting or anorexia, three remedies have been suggested:
 - 1) Give the same total daily dose, but divide into smaller individual doses and give more frequently
 - 2) Temporarily reduce the daily dose and gradually increase to recommended dosage, or
 - 3) Give with meals (will probably reduce amount of drug absorbed).

Chemistry/Synonyms

A monothiol chelating agent that is a degradation product of penicillins, penicillamine occurs as a white or practically white, crystalline powder with a characteristic odor. Penicillamine is freely soluble in water and slightly soluble in alcohol with pK_a values of 1.83, 8.03, and 10.83.

Penicillamine may also be known as: D-Penicillamine, beta,beta-Dimethylcysteine, D-3-Mercaptovalline, penicillaminum, *Depen*® and *Cuprimine*®.

Storage/Stability

Penicillamine should be stored at room temperature (15–30°C). The capsules should be stored in tight containers; tablets in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Penicillamine Titrateable Tablets: 250 mg (scored); *Depen*® (Wallace); (Rx)

Penicillamine Capsules: 125 mg & 250 mg; *Cuprimine*® (Merck); (Rx)

PENICILLINS, GENERAL INFORMATION (pen-i-sill-in)

Uses/Indications

Penicillins have been used for a wide range of infections in various species. FDA-approved indications/species, as well as non-approved uses, are listed in the Uses/Indications and Dosage section for each drug.

Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The clinically available penicillins encompass several distinct classes of compounds with varying spectrums of activity: The so-called natural penicillins including penicillin G and V; the penicillinase-resistant penicillins including cloxacillin, dicloxacillin, oxacillin, nafcillin, and methicillin; the aminopenicillins including ampicillin, amoxicillin, cyclacillin, hetacillin, and bacampicillin; extended-spectrum penicillins including carbenicillin, ticarcillin, piperacillin, azlocillin, and mezlocillin; and the potentiated penicillins including amoxicillin-potassium clavulanate, ampicillin-sulbactam, piperacillin-tazobactam, and ticarcillin-potassium clavulanate.

The natural penicillins (G and K) have similar spectrums of activity, but penicillin G is slightly more active *in vitro* on a weight basis against many organisms. This class of penicillin has *in vitro* activity against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase-producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as *Bacillus anthracis*, *Clostridium* spp. (not *C. difficile*), *Fusobacterium*, and *Actinomyces*. The natural penicillins are customarily inactive against most gram-negative aerobic and anaerobic bacilli, and all Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

The penicillinase-resistant penicillins have a narrower spectrum of activity than the natural penicillins. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly staphylococcal species; these drugs are sometimes called anti-staphylococcal penicillins. There are documented strains of *Staphylococcus* that are resistant to these drugs (so-called methicillin-resistant or oxacillin-resistant Staph), but these strains have only begun to be a significant problem in veterinary species. While this class of penicillins does have activity against some other gram-positive and gram-negative aerobes and anaerobes, other antibiotics are usually better choices. The penicillinase-resistant penicillins are inactive against Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

The aminopenicillins, also called the "broad-spectrum" or ampicillin penicillins, have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *E. coli*, *Klebsiella*, and *Haemophilus*. Like the natural penicillins, they are susceptible to inactivation by beta-lactamase-producing bacteria (e.g., *Staph aureus*). Although not as active as the natural penicillins, they do have activity against many anaerobic bacteria, including Clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa*, *Serratia*, Indole-positive *Proteus* (*Proteus mirabilis* is susceptible), *Enterobacter*, *Citrobacter*, and *Acinetobacter*. The aminopenicillins also are inactive against Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

The extended-spectrum penicillins, sometimes called anti-pseudomonal penicillins, include both alpha-carboxypenicillins

(carbenicillin and ticarcillin) and acylaminopenicillins (piperacillin, azlocillin, and mezlocillin). These agents have similar spectrums of activity as the aminopenicillins but with additional activity against several gram-negative organisms of the family Enterobacteriaceae, including many strains of *Pseudomonas aeruginosa*. Like the aminopenicillins, these agents are susceptible to inactivation by beta-lactamases.

In order to reduce the inactivation of penicillins by beta-lactamases, potassium clavulanate and sulbactam have been developed to inactivate these enzymes and extend the spectrum of those penicillins. When used with penicillin, these combinations are often effective against many beta-lactamase-producing strains of otherwise resistant *E. coli*, *Pasturella* spp., *Staphylococcus* spp., *Klebsiella*, and *Proteus*. Type I beta-lactamases are often associated with *E. coli*, *Enterobacter*, and *Pseudomonas*, and not generally inhibited by clavulanic acid.

Pharmacokinetics (General)

The oral absorption characteristics of the penicillins are dependent upon its class. Penicillin G is the only available oral penicillin that is substantially affected by gastric pH and can be completely inactivated at a pH of less than 2. The other orally available penicillins are resistant to acid degradation but bioavailability can be decreased (not amoxicillin) by the presence of food. Of the orally administered penicillins, penicillin V and amoxicillin tend to have the greatest bioavailability in their respective classes.

Penicillins are generally distributed widely throughout the body. Most drugs attain therapeutic levels in the kidneys, liver, heart, skin, lungs, intestines, bile, bone, prostate, and peritoneal, pleural, and synovial fluids. Penetration into the CSF and eye only occur with inflammation and may not reach therapeutic levels. Penicillins are bound in varying degrees to plasma proteins and cross the placenta.

Most penicillins are rapidly excreted largely unchanged by the kidneys into the urine via glomerular filtration and tubular secretion. Probenecid can prolong half-lives and increase serum levels by blocking the tubular secretion of penicillins. Except for nafcillin and oxacillin, hepatic inactivation and biliary secretion is a minor route of excretion.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses, as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases. Certain species (snakes, birds, turtles, Guinea pigs, and chinchillas) are reportedly sensitive to procaine penicillin G.

High doses of penicillin G sodium or potassium, particularly in small animals with a preexisting electrolyte abnormality, renal disease, or congestive heart failure may cause electrolyte imbalances. Other injectable penicillins, such as ticarcillin, carbenicillin, and ampicillin, have significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neu-

tropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Some penicillins (ticarcillin, carbenicillin, azlocillin, mezlocillin, piperacillin and nafcillin) have been implicated in causing bleeding problems in humans. These drugs are infrequently used systemically in veterinary species and veterinary ramifications of this effect are unclear.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) However, use only when the potential benefits outweigh the risks.

Penicillins are excreted in maternal milk in low concentrations; use potentially could cause diarrhea, candidiasis, or allergic response in the nursing offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillins and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **BACTERIOSTATIC ANTIBIOTICS** (e.g., **chloramphenicol**, **erythromycin**, **tetracyclines**): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly as penicillins tend to perform better on actively growing bacteria.
- **PROBENECID:** Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations

- Penicillins may cause false-positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by penicillin.

- In humans, clavulanic acid and high dosages of piperacillin have caused a false-positive direct **Combs' test**.
- As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of **aminoglycosides** may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop.
- Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Owners should be instructed to give oral penicillins on an empty stomach, unless using amoxicillin or GI effects (anorexia, vomiting) occur.
- Compliance with the therapeutic regimen should be stressed.
- Reconstituted oral suspensions should be kept refrigerated and discarded after 14 days, unless labeled otherwise.

PENICILLIN G

(pen-i-sill-in jee)

PENICILLIN ANTIBIOTIC

Prescriber Highlights

- ▶ Prototypical penicillin agent used for susceptible gram-positive aerobes & anaerobes; best used parenterally
- ▶ Contraindications: Known hypersensitivity (unless no other options)
- ▶ Adverse Effects: Hypersensitivity possible. Very high doses may cause CNS effects.
- ▶ Benzathine penicillin only effective against extremely sensitive agents
- ▶ Certain species may be sensitive to procaine penicillin G

Uses/Indications

Natural penicillins remain the drugs of choice for a variety of bacteria, including group A beta-hemolytic streptococci, many gram-positive anaerobes, spirochetes, gram-negative aerobic cocci, and some gram-negative aerobic bacilli. Generally, if a bacteria remains susceptible to a natural penicillin, either penicillin G or V is preferred for treating that infection as long as adequate penetration of the drug to the site of the infection occurs and the patient is not hypersensitive to penicillins.

Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall

synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The natural penicillins (G and K) have similar spectrums of activity, but penicillin G is slightly more active *in vitro* on a weight basis against many organisms. This class of penicillin has *in vitro* activity against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as *Bacillus anthracis*, *Clostridium* spp. (not *C. difficile*), *Fusobacterium*, and *Actinomyces*. The natural penicillins are customarily inactive against most gram-negative aerobic and anaerobic bacilli, and all Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

Pharmacokinetics

Penicillin G potassium is poorly absorbed orally because of rapid acid-catalyzed hydrolysis. When administered on an empty (fasted) stomach, oral bioavailability is only about 15–30%. If given with food, absorption rate and extent will be decreased.

Penicillin G potassium and sodium salts are rapidly absorbed after IM injections and yield high peak levels usually within 20 minutes of administration. In horses, equivalent doses given either IV or IM demonstrated that IM dosing will provide serum levels above 0.5 micrograms/mL for about twice as long as IV administration [approx. 3–4 hours (IV) vs. 6–7 hours (IM)].

Procaine penicillin G is slowly hydrolyzed to penicillin G after IM injection. Peak levels are much lower than with parenterally administered aqueous penicillin G sodium or potassium, but serum levels are more prolonged.

Benzathine penicillin G is also very slowly absorbed after IM injections after being hydrolyzed to the parent compound. Serum levels can be very prolonged, but levels attained generally only exceed MIC's for the most susceptible streptococci, and the use of benzathine penicillin G should be limited to these infections when other penicillin therapy is impractical.

After absorption, penicillin G is widely distributed throughout the body with the exception of the CSF, joints and milk. In lactating dairy cattle, the milk to plasma ratio is about 0.2. CSF levels are generally only 10% or less of those found in the serum when meninges are not inflamed. Levels in the CSF may be greater in patients with inflamed meninges or if probenecid is given concurrently. Binding to plasma proteins is approximately 50% in most species.

Penicillin G is principally excreted unchanged into the urine through renal mechanisms via both glomerular filtration and tubular secretion. Elimination half-lives are very rapid and are usually one hour or less in most species (if normal renal function exists).

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished; parenteral (preferably IV) routes should be used for these cases.

High doses of penicillin G sodium or potassium, particularly in small animals with a preexisting electrolyte abnormality, renal disease, or congestive heart failure may cause electrolyte imbalances.

Other injectable penicillins, such as ticarcillin, carbenicillin, and ampicillin, have significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

Certain species (snakes, birds, turtles, Guinea pigs, and chinchillas) are reportedly sensitive to procaine penicillin G.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Penicillins are excreted in maternal milk in low concentrations; use could potentially cause diarrhea, candidiasis, or allergic responses in nursing offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects). In humans, very high dosages of parenteral penicillins, especially those with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillin G and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **BACTERIOSTATIC ANTIBIOTICS** (e.g., chloramphenicol, erythromycin, tetracyclines): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferat-

ing rapidly as penicillins tend to perform better on actively growing bacteria.

- **METHOTREXATE:** Penicillins may decrease renal elimination of MTX
- **PROBENECID:** Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- Penicillin G can cause falsely elevated **serum uric acid** values if the copper-chelate method is used; phosphotungstate and uricase methods are not affected
- Penicillins may cause false-positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by penicillin.

Doses

■ DOGS:

For susceptible infections:

a) *Penicillin G potassium:*

For bacteremia, systemic infections: 20,000–40,000 Units/kg IV q4–6h for as long as necessary.

For orthopedic infections: 20,000–40,000 Units/kg IV q6h for as long as necessary.

Prophylaxis for orthopedic surgery: 40,000 Units/kg IV one hour prior to surgery, and if surgery lasts longer than 90 minutes a second dose is given.

For soft tissue infections: 40,000–60,000 Units/kg PO q8h for as long as necessary.

Penicillin G procaine: 20,000–40,000 Units/kg IM, SC q12–24h for as long as necessary.

Penicillin G benzathine: 40,000 IU/kg IM q5 days. (Greene, Hartmann et al. 2006)

b) *Penicillin G potassium/sodium:* 20,000 Units/kg IV, IM, or SC q6h

Penicillin G procaine: 22,000 Units/kg IM, SC q12h. Doses may be increased to 80,000 IU/kg per day; Actinomyces infections may require 100,000–200,000 IU/kg IM daily. (Ford and Aronson 1985)

c) *Penicillin G potassium/sodium:* 20,000 Units/kg IV, IM, q4h or 40,000 IU/kg PO on an empty stomach q6h

Penicillin G procaine: 20,000 Units/kg IM, SC q12–24h.

Penicillin G benzathine: 40,000 IU/kg q5 days IM (Kirk 1989)

d) For leptospiremia: 25,000–40,000 U/kg IV or IM q12–24h for 14 days. For the renal carrier state of leptospirosis: Doxycycline 5–10 mg/kg PO twice daily of doxycycline for an additional 14 days after penicillin G therapy (Ross and Rentko 2000)

e) For adjunctive therapy of septicemia: Penicillin G sodium/potassium: 25,000 IU/kg IV q6h. Too rapid IV infusions may cause neurologic signs; hypersensitivity may also occur. (Goodwin and Schaer 1989)

■ CATS:

For susceptible infections:

a) *Penicillin G potassium:*

For soft tissue, systemic infections: 40,000 IU/kg PO q6–8h for as long as necessary.

Penicillin G procaine:

For soft tissue infections: 20,000 Units/kg IM, SC q12h for as long as necessary.

For orthopedic infections: 20,000–40,000 Units/kg IM q8h for as long as necessary.

For resistant organisms (Actinomyces): 50,000–100,000 Units/kg IM, SC q12h for as long as necessary.

Penicillin G benzathine: 50,000 IU/kg IM q5 days. (Greene, Hartmann et al. 2006)

b) *Penicillin G potassium/sodium:* 20,000–40,000 Units/kg IV, IM, q6h

Penicillin G procaine: 22,000 Units/kg IM, SC q12h. Doses may be increased to 80,000 IU/kg per day; Actinomyces infections may require 100,000–200,000 IU/kg IM daily (Ford and Aronson 1985)

c) *Penicillin G potassium/sodium:* 20,000 Units/kg IV, IM, q4h or 40,000 IU/kg PO on an empty stomach q6h

Penicillin G procaine: 20,000 Units/kg IM, SC q12–24h.

Penicillin G benzathine: 40,000 IU/kg q5 days IM (Kirk 1989)

d) *Penicillin G sodium or potassium:* 22,000–55,000 IU/kg IV or IM q6–8h (Aronson and Aucoin 1989)

■ FERRETS:

For susceptible infections:

a) Procaine Pen G: 20,000–40,000 IU/kg IM once a day to twice daily;

Sodium or potassium Pen G: 20,000 IU/kg SC, IM or IV q4h or 40,000 IU/kg PO three times daily (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

a) Rabbits: Penicillin G Procaine 20,000–84,000 IU/kg SC, IM q24h for 5–7 days for venereal spirochetosis (Ivey and Morrisey 2000)

b) Hedgehogs: 40,000 IU/kg IM once daily (Smith 2000)

■ CATTLE (and other ruminants unless specified):

For susceptible infections:

a) *Penicillin G procaine:* 44,000–66,000 Units/kg IM, SC once daily

Penicillin G benzathine: 44,000–66,000 Units/kg IM, or SC q2days (Upson 1988)

b) For bovine respiratory disease complex: Procaine penicillin G 66,000 IU/kg IM or SC once daily. Recommend 20–day slaughter withdrawal at this dosage. (Hjerpe 1986)

c) *Procaine penicillin G:* 40,000 IU/kg IM once daily

Procaine penicillin G/benzathine penicillin G combination: 40,000 IU/kg IM once (Howard 1986)

d) *Procaine penicillin G:* 10,000–20,000 IU/kg IM q12–24h.

Benzathine penicillin G: 10,000–20,000 IU/kg, IM, SC q48h (Jenkins 1986)

■ HORSES:

For susceptible infections:

a) For gram-positive aerobes: Penicillin G potassium or sodium: 10,000–20,000 Units/kg IV or IM q6h.

For serious gram-positive infections (e.g., tetanus, botulism, *C. difficile* enterocolitis in foals): Penicillin G sodium or potassium 22,000–44,000 Units/kg IV q6h

Susceptible bacterial infections: Penicillin G procaine: 22,000–44,000 Units/kg IM q12h (Whittem 1999)

- b) Treatment of carriers with *S. equi* infections of the guttural pouches: Administration of both systemic and topical penicillin G appears to improve treatment success rate. Before topical therapy, remove all visible inflammatory material removed from guttural pouch. To make a gelatin/penicillin G mix of 50 mL for guttural pouch instillation:

- 1) Weigh out 2 grams gelatin (Sigma G-6650 or household) and add 40 mL of sterile water.
- 2) Heat or microwave to dissolve. Cool to 45–50°C,
- 3) Add 10 mL sterile water to a 10 million unit sodium penicillin G for injection vial and mix with the cooled gelatin to total volume of 50 mL.
- 4) Dispense into syringes and leave overnight in the refrigerator.

Instillation is easiest through a catheter inserted up the nose and endoscopically guided into the pouch opening with the last inch bent at an angle to aid entry under the pouch flap. Elevate horse's head for 20 minutes after infusion. (Verheyen, Newton et al. 2000)

- c) For treatment of botulism: Penicillin G sodium or potassium 22,000–44,000 IU/kg IV four times daily (do not use oral penicillin therapy) (Johnston and Whitlock 1987)
- d) For strangles: Early in infection when only fever and depression are present: procaine penicillin G 22,000 IU/kg IM or SC q12h, or aqueous salts (sodium or potassium) penicillin G 22,000 IU/kg IM, IV or SC q6h. If lymphadenopathy noted in otherwise healthy and alert horse do not treat. If lymphadenopathy present and horse is depressed, febrile, anorexic and especially if dyspneic, treat as above. (Foreman 1999)
- e) For foals: Penicillin G Na or K: 20,000–50,000 U/kg IV q6–8h; Procaine penicillin G 22,000–50,000 U/kg IM q12h (Brumbaugh 1999)
- f) For foals: Penicillin G sodium or potassium: 20,000–50,000 U/kg IV q6h Penicillin G Procaine: 20,000–50,000 U/kg IM q6h (Furr 1999)

■ SWINE:

For susceptible infections:

- a) Procaine penicillin G: 40,000 IU/kg IM once daily.
Procaine penicillin G/benzathine penicillin G combination: 40,000 IU/kg IM once (Howard 1986)
- b) Procaine penicillin G: 6,600 IU/kg IM once daily for not more than 4 days
Procaine penicillin G/benzathine penicillin G combination: 11,000–22,000 IU/kg IM once (Wood 1986)

■ BIRDS:

For susceptible infections:

- a) In turkeys: Procaine penicillin G/benzathine penicillin G combination: 100 mg/kg IM of each drug once a day or every 2 days. Use cautiously in small birds as it may cause procaine toxicity. (Clubb 1986)

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Owners should be instructed to give oral penicillins to animals with an empty stomach, unless using amoxicillin or if GI effects (anorexia, vomiting) occur.
- Compliance with the therapeutic regimen should be stressed.

Chemistry/Synonyms

Penicillin G is considered natural penicillin and is obtained from cultures *Penicillium chrysogenum* and is available in several different salt forms. Penicillin G potassium (also known as benzylpenicillin potassium, aqueous or crystalline penicillin) occurs as colorless or white crystals, or white crystalline powder. It is very soluble in water and sparingly soluble in alcohol. Potency of penicillin G potassium is usually expressed in terms of Units. One mg of penicillin G potassium is equivalent to 1440–1680 USP Units (1355–1595 USP Units for the powder for injection). After reconstitution, penicillin G potassium powder for injection has a pH of 6–8.5, and contains 1.7 mEq of potassium per 1 million Units.

Penicillin G sodium (also known as benzylpenicillin sodium, aqueous or crystalline penicillin) occurs as colorless or white crystals, or white to slightly yellow, crystalline powder. Approximately 25 mg are soluble in 1 mL of water. Potency of penicillin G sodium is usually expressed in terms of Units. One mg of penicillin G sodium is equivalent to 1500–1750 USP Units (1420–1667 USP Units for the powder for injection). After reconstitution, penicillin G sodium powder for injection has a pH of 6–7.5, and contains 2 mEq of sodium per 1 million Units.

Penicillin G procaine (also known as APPG, Aqueous Procaine Penicillin G, Benzylpenicillin Procaine, Procaine Penicillin G, Procaine Benzylpenicillin) is the procaine monohydrate salt of penicillin G. *In vivo* it is hydrolyzed to penicillin G and acts as a depot, or repository form, of penicillin G. It occurs as white crystals or very fine, white crystalline powder. Approximately 4–4.5 mg are soluble in 1 mL of water and 3.3 mg are soluble in 1 mL of alcohol. Potency of penicillin G procaine is usually expressed in terms of Units. One mg of penicillin G procaine is equivalent to 900–1050 USP Units. The commercially available suspension for injection is buffered with sodium citrate and has a pH of 5–7.5. It is preserved with methylparaben and propylparaben.

Penicillin G Benzathine (also known as Benzathine Benzylpenicillin, Benzathine Penicillin G, Benzylpenicillin Benzathine, Dibenzylethylenediamine Benzylpenicillin) is the benzathine tetrahydrate salt of penicillin G. It is hydrolyzed *in vivo* to penicillin G and acts as a long-acting form of penicillin G. It occurs as an odorless, white, crystalline powder. Solubilities are 0.2–0.3 mg/mL of water and 15 mg/mL of alcohol. One mg of penicillin G benzathine is equivalent to 1090–1272 USP Units. The commercially available suspension for injection is buffered with sodium citrate and has a pH of 5–7.5. It is preserved with methylparaben and propylparaben.

Penicillin G may also be known as: benzylpenicillin, crystalline penicillin G, penicillin, *Bicillin C-R*®, *Masti-Clear*®, *Permapen*®, and *Pfizerpen*®.

Storage/Stability/Compatibility

Penicillin G sodium and potassium should be protected from moisture to prevent hydrolysis of the compounds. Penicillin G potassium tablets and powder for oral solution should be stored at room temperature in tight containers; avoid exposure to excessive heat. After reconstituting, the oral powder for solution should be stored from 2–8°C (refrigerated) and discarded after 14 days.

Penicillin G sodium and potassium powder for injection can be stored at room temperature (15–30°C). After reconstituting, the injectable solution is stable for 7 days when kept refrigerated (2–8°C) and for 24 hours at room temperature.

Penicillin G procaine should be stored at 2–8°C; avoid freezing. Benzathine penicillin G should be stored at 2–8°C.

All commonly used IV fluids (some Dextran products are physically **incompatible**) and the following drugs are reportedly physically **compatible** with penicillin G potassium: ascorbic acid injection, calcium chloride/gluconate, cephapirin sodium, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, colistimethate sodium, corticotropin, dimenhydrinate, diphenhydramine HCl, ephedrine sulfate, erythromycin gluceptate/lactobionate, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, methicillin sodium, methylprednisolone sodium succinate, metronidazole with sodium bicarbonate, nitrofurantoin sodium, polymyxin B sulfate, potassium chloride, prednisolone sodium phosphate, procaine HCl, prochlorperazine edisylate, sodium iodide, sulfoxazole diolamine, and verapamil HCl.

The following drugs/solutions are either physically **incompatible** or **data conflicts** regarding compatibility with penicillin G potassium injection: amikacin sulfate, aminophylline, cephalothin sodium, chlorpromazine HCl, dopamine HCl, heparin sodium, hydroxyzine HCl, lincomycin HCl, metoclopramide HCl, oxytetracycline HCl, pentobarbital sodium, prochlorperazine mesylate, promazine HCl, promethazine HCl, sodium bicarbonate, tetracycline HCl, and vitamin B-complex with C.

The following drugs/solutions are reportedly physically **compatible** with penicillin G sodium injection: Dextran 40 10%, dextrose 5% (some degradation may occur if stored for 24 hours), sodium chloride 0.9% (some degradation may occur if stored for 24 hours), calcium chloride/gluconate, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, colistimethate sodium, diphenhydramine HCl, erythromycin lactobionate, gentamicin sulfate, hydrocortisone sodium succinate, kanamycin sulfate, methicillin sodium, nitrofurantoin sodium, polymyxin B sulfate, prednisolone sodium phosphate, procaine HCl, verapamil HCl, and vitamin B-complex with C.

The following drugs/solutions are either physically **incompatible** or **data conflicts** regarding compatibility with penicillin G sodium injection: amphotericin B, bleomycin sulfate, cephalothin sodium, chlorpromazine HCl, heparin sodium, hydroxyzine HCl, lincomycin HCl, methylprednisolone sodium succinate, oxytetracycline HCl, potassium chloride, prochlorperazine mesylate, promethazine HCl and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Note: Withdrawal times are for labeled dosages only.

Penicillin G Procaine Injection 300,000 Units/mL in 100 mL and 250 mL vials: Variety of trade names available. Depending on product, approved for use in: cattle, sheep, horses, and swine. Not intended for use in horses used for food. Do not exceed 7 days of treatment in non-lactating dairy cattle, beef cattle, swine or sheep; 5 days in lactating dairy cattle. Treatment should not exceed 4 consecutive days.

Withdrawal times vary depending on the product are for the labeled dosage of 6,600 U/kg once daily (rarely used clinically today). Actual withdrawal times may be longer. Milk withdrawal times (at labeled doses) = 48 hours. Slaughter withdrawal: Calves (non-ruminating) =

7 days; cattle = 4–10 days; sheep = 8–9 days; swine = 6–7 days; refer to label for more information.

Penicillin G Procaine Mastitis Syringes 100,000 units/mL in 10 mL units: *Go-Dry*® (G.C. Hanford) (OTC) Milk withdrawal (at labeled doses) = 72 hours. Slaughter withdrawal (at labeled doses) = 14 days. For use in dry cows only. *Masti-Clear*® (G.C. Hanford) Milk withdrawal (at labeled doses) = 60 hours. Slaughter withdrawal (at labeled doses) = 3 days. Administer no more than 3 consecutive doses or withdrawal times must lengthen.

There are also mastitis syringes in combination with novobiocin (*Albadry Plus*®) or dihydrostreptomycin (*Quartermaster*®).

Penicillin G Benzathine 150,000 U/mL with *Penicillin G Procaine Injection* 150,000 Units/mL for Injection in 100 mL and 250 mL vials: Variety of trade names available. Approved (most products) in horses and beef cattle. Not approved for horses intended for food use. Slaughter withdrawal: cattle = 30 days (at labeled doses). Actual species approvals and withdrawal times may vary with the product; refer to the label of the product you are using.

HUMAN-LABELED PRODUCTS:

Penicillin G (Aqueous) Sodium Powder for Injection: 5,000,000 units & 20,000,000 units in vials; *Pfizerpen*® (Pfizer); generic (Sandoz); (Rx)

Penicillin G (Aqueous) Potassium Injection (Premixed, frozen): 1,000,000 units, 2,000,000 units & 3,000,000 units in 50 mL Galaxy containers; generic (Baxter); (Rx)

Penicillin G (Procaine Injection: 600,000 Units/vial in 1 mL *Tubex* & 1,200,000 Units/vial in 2 mL *Tubex*; generic; (Monarch); (Rx)

Penicillin G Benzathine IM Injection: 600,000 units/dose in 1 mL *Tubex*; 1,200,000 units/dose in 2 mL *Tubex* and 2 mL *Isoject*; 2,400,000 units/dose in 4 mL pre-filled syringes; *Bicillin L-A*® (Monarch); *Permapen*® (Roerig); (Rx)

Penicillin G Benzathine/Penicillin G Procaine IM Injection: 600,000 units/dose (300,000 units each penicillin G benzathine and penicillin G procaine) in 1 mL *Tubex*; 1,200,000 units/dose (600,000 units each penicillin G benzathine and penicillin G procaine) in 2 mL *Tubex*; 2,400,000 units/dose (1,200,000 units each penicillin G benzathine and penicillin G procaine) in 4 mL syringes; 1,200,000 units/dose (900,000 units penicillin G benzathine and 300,000 units penicillin G procaine) in 2 mL *Tubex*; *Bicillin C-R*® and *Bicillin C-R 900/300*® (Monarch); (Rx)

PENICILLIN V POTASSIUM

(pen-i-sill-in Vee) Phenoxyethylpenicillin

ORAL PENICILLIN ANTIBIOTIC

Prescriber Highlights

- Oral natural penicillin
- Contraindications: Known hypersensitivity (unless no other options)
- Adverse Effects: GI effects or hypersensitivity possible
- Best to give on an empty stomach

Uses/Indications

Penicillins have been used for a wide range of infections in various species. See the dosage section for more information.

Pharmacology/Actions

The natural penicillins (G and K) have similar spectrums of activity, but penicillin G is slightly more active *in vitro* on a per weight basis against many organisms. This class of penicillin has *in vitro* activity against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as *Bacillus anthracis*, *Clostridium* spp. (not *C. difficile*), *Fusobacterium*, and *Actinomyces*. The natural penicillins are customarily inactive against most gram-negative aerobic and anaerobic bacilli, and all Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses. Although penicillin V may be slightly less active than penicillin G against organisms susceptible to the natural penicillins, its superior absorptive characteristics after oral administration make it a better choice against mild to moderately severe infections when oral administration is desired in monogastric animals.

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

Pharmacokinetics

The pharmacokinetics of penicillin V are very similar to penicillin G with the exception of oral bioavailability and the percent of the drug that is bound to plasma proteins. Penicillin V is significantly more resistant to acid-catalyzed inactivation in the gut and bioavailability after oral administration in humans is approximately 60–73%. In veterinary species, bioavailability in calves is only 30%, but studies performed in horses and dogs demonstrated that therapeutic serum levels can be achieved after oral administration. In dogs, food will decrease the rate and extent of absorption.

Distribution of penicillin V follows that of penicillin G but, at least in humans, the drug is bound to a larger extent to plasma proteins (approximately 80% with penicillin V vs. 50% with penicillin G).

Like penicillin G, penicillin V is excreted rapidly in the urine via the kidney. Elimination half-lives are generally less than 1 hour in animals with normal renal function; an elimination half-life of 3.65 hours has been reported after oral dosing in horses (Schwark et al. 1983).

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. Certain species (snakes, birds, turtles, Guinea pigs, and chinchillas) are reported to be sensitive to penicillins. High doses of penicillin G sodium or potassium, particularly in small animals with a preexisting electrolyte abnormality, renal disease, or congestive heart failure may cause electrolyte imbalances. Other injectable penicillins, such as ticarcillin, carbenicillin, and ampicillin, have significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters*).

Penicillins are excreted in maternal milk in low concentrations; use could potentially cause diarrhea, candidiasis, or allergic response in nursing offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillin V potassium and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **BACTERIOSTATIC ANTIBIOTICS** (e.g., chloramphenicol, erythromycin, tetracyclines): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly as penicillins tend to perform better on actively growing bacteria.

- **METHOTREXATE:** Penicillins may decrease renal elimination of MTX
- **PROBENECID:** Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- Penicillin V can cause falsely elevated **serum uric acid** values if the copper-chelate method is used; phosphotungstate and uricase methods are not affected
- Penicillins may cause false-positive **urine glucose** determinations when using cupric-sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by penicillin.

Doses

■ DOGS:

For susceptible infections:

- 5.5–11 mg/kg PO q6–8h (Aronson and Aucoin 1989)
- For soft tissue infections: 10 mg/kg PO q8h for 7 days. (Greene, Hartmann et al. 2006)

■ CATS:

For susceptible infections:

- 5.5–11 mg/kg PO q6–8h (Aronson and Aucoin 1989)
- For soft tissue infections: 10 mg/kg PO q8h for 7 days. (Greene, Hartmann et al. 2006)

■ HORSES:

For susceptible infections:

- 110,000 U/kg (68.75 mg/kg) PO q8h (may yield supra-optimal levels against uncomplicated infections by sensitive organisms) (Schwark et al. 1983)
- 110,000 U/kg PO q6–12h (Brumbaugh 1987)

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Unless otherwise instructed by the veterinarian, this drug should be given on an empty stomach, at least 1 hour before feeding or 2 hours after feeding
- Keep oral suspension in the refrigerator and discard any unused suspension after 14 days

Chemistry/Synonyms

A natural-penicillin, penicillin V is produced from *Penicillium chrysogenum* and is usually commercially available as the potassium salt. Penicillin V potassium occurs as an odorless, white, crystalline powder that is very soluble in water and slightly soluble in alcohol. Potency of penicillin V potassium is usually expressed in terms of weight (in mg) of penicillin V, but penicillin V units may also be used. One mg of penicillin V potassium is equivalent to 1380–1610 USP Units of penicillin V. Manufacturers however generally state that 125 mg of penicillin V potassium is approximately equivalent to 200,000 USP units of penicillin V.

Penicillin V may also be known as: phenoxymethylpenicillin, fenoximetilpenicilina, penicillin, phenoxymethyl, phenomycil-line, phenoxymethyl penicillin, phenoxymethylpenicillinum, and *Veetids*®.

Storage/Stability

Penicillin V potassium tablets and powder for oral solution should be stored in tight containers at room temperature (15–30°C). After reconstitution, the oral solution should be stored at 2–8°C (refrigerated) and any unused portion discarded after 14 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Penicillin V Potassium Tablets: 250 mg & 500 mg; *Veetids*® (Geneva); generic; (Rx)

Penicillin V Potassium Powder for Oral Solution: 25 mg/mL and 50 mg/mL in 100 mL and 200 mL; *Veetids*® (Geneva); generic; (Rx)

PENTAZOCINE LACTATE PENTAZOCINE HCL

(pen-taz-oh-seen) Talwin®

PARTIAL OPIATE AGONIST

Prescriber Highlights

- ▶ Partial opiate agonist analgesic used in a variety of species; usage is decreasing
- ▶ Contraindications: Known hypersensitivity
- ▶ Caution: Head trauma, increased CSF pressure or other CNS dysfunction, hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), & geriatric or severely debilitated patients
- ▶ Not a replacement for surgery or medical treatment for horses with colic
- ▶ Adverse Effects: **HORSES:** Transient ataxia, CNS excitement, increased pulse, & respiratory rate. **DOGS:** Salivation most prevalent; ataxia, fine tremors, seizures, emesis, & swelling at injection site possible
- ▶ **CATS:** Use is controversial; may cause dysphoric reactions
- ▶ C-IV controlled substance

Uses/Indications

Pentazocine is labeled for the symptomatic relief of pain of colic in horses and for the amelioration of pain accompanying postoperative recovery from fractures, trauma, and spinal disorders in dogs. It has also been used as an analgesic in cats (see Adverse Effects below) and swine.

Pharmacology/Actions

While considered a partial opiate agonist, pentazocine exhibits many of the same characteristics as the true opiate agonists. It is reported to have an analgesic potency of approximately one-half that of morphine and five times that of meperidine. It is a very weak antagonist at the *mu* opioid receptor when compared to naloxone.

It will not antagonize the respiratory depression caused by drugs like morphine, but may induce symptoms of withdrawal in human patients physically dependent on narcotic agents.

Besides its analgesic properties, pentazocine can cause respiratory depression, decreased GI motility, sedation, and it possesses antitussive effects. Pentazocine tends to have less sedative qualities in animals than other opiates and is usually not used as a pre-operative medication.

In dogs, pentazocine can cause a transient decrease in blood pressure; in humans, increases in cardiac output, heart rate, and blood pressure can be seen.

Pharmacokinetics

Pentazocine is well absorbed following oral, IM, or SC administration. Because of a high first-pass effect, only about 20% of an oral dose will enter the systemic circulation in patients with normal hepatic function.

After absorption, the drug is distributed widely into tissues. In the equine, it has been shown to be 80% bound to plasma proteins. Pentazocine will cross the placenta and neonatal serum levels have been measured at 60–65% of maternal levels at delivery. It is not clearly known if or how much pentazocine crosses into milk.

The drug is primarily metabolized in the liver with resultant excretion by the kidneys of the metabolites. In the horse, approximately 30% of a given dose is excreted as the glucuronide. Pentazocine and its metabolites have been detected in equine urine for up to 5 days following an injection. Apparently, less than 15% of the drug is excreted by the kidneys in an unchanged form.

Plasma half-lives have been reported for various species: Humans = 2–3 hrs; Ponies = 97 min.; Dogs = 22 min.; Cats = 84 min.; Swine = 49 min. Volumes of distribution range from a high of 5.09 L/kg in ponies to 2.78 L/kg in cats. In horses, the onset of action has been reported to be 2–3 minutes following IV dosing with a peak effect at 5–10 minutes.

Contraindications/Precautions/Warnings

The drug is contraindicated in patients having known hypersensitivity to it. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and geriatric or severely debilitated patients.

Like other opiates, pentazocine must be used with extreme caution in patients with head trauma, increased CSF pressure or other CNS dysfunction (e.g., coma). Pentazocine should not be used in place of appropriate therapy (medical &/or surgical) for equine colic, but only as adjunctive treatment for pain.

Adverse Effects

In dogs, the most predominant adverse reaction following parenteral administration is salivation. Other potential side effects at usual doses include fine tremors, emesis, and swelling at the injection site. At very high doses (6 mg/kg) dogs have been noted to develop ataxia, fine tremors, convulsions, and swelling at the injection site.

Horses may develop transient ataxia and clinical signs of CNS excitement. Pulse and respiratory rates may be mildly elevated.

The use of pentazocine in cats is controversial. Some clinicians claim that the drug causes dysphoric reactions that preclude its use in this species, while others disagree and state that drug may be safely used.

Reproductive/Nursing Safety

Because reproductive studies have not been done in dogs, the manufacturer does not recommend its use in pregnant bitches or bitches intended for breeding. Studies performed in laboratory animals have not demonstrated any indications of teratogenicity. In

humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Safety for use during lactation has not been established.

Overdosage/Acute Toxicity

There is little information regarding acute overdose situations with pentazocine. For oral ingestions, the gut should be emptied if indicated and safe to do so. Clinical signs should be managed by supportive treatment (O₂, pressor agents, IV fluids, mechanical ventilation) and respiratory depression can be treated with naloxone. Repeated doses of naloxone may be necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pentazocine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER** (e.g., **anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol**, etc.): May cause increased CNS or respiratory depression; dosage may need to be decreased
- **FLUOXETINE** (and **OTHER SSRI'S**): May be at increased risk for serotonin syndrome

Laboratory Considerations

- Pentazocine may cause decreases for urinary **17-hydroxycorticosteroid** determinations

Doses

■ DOGS:

For analgesia:

- a) Initially 1.65 mg/kg; up to 3.3 mg/kg IM. Duration of effect generally lasts 3 hours. If dose is repeated, use different injection site. (Package Insert; *Talwin*®-V—Winthrop)
- b) 1–6 mg/kg IM or SC q1–3h (Hendrix and Hansen 2000)
- c) 1–4 mg/kg IM, IV q2–4h (Otero 2006a)

■ CATS:

Note: Pentazocine can cause dysphoria in cats; alternative analgesics are recommended.

■ FERRETS:

- a) 5–10 mg/kg SC or IM q4h (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: Post-operative analgesia: 5–20 mg/kg SC, IV, or IM q4h (Ivey and Morrissey 2000)

■ HORSES:

Studies have demonstrated that pentazocine is not as an effective analgesic as either butorphanol or flunixin in horses. Many clinicians no longer recommend its use. (**Note:** ARCI UCGFS Class 3 Drug)

For analgesia:

- a) 0.33 mg/kg slowly in jugular vein. In cases of severe pain, a second dose (0.33 mg/kg) be given IM 15 minutes later (Package Insert; *Talwin*®-V—Winthrop)
- b) 0.4–0.9 mg/kg IV. Duration of analgesia may last only 10–30 minutes following an IV dose. (Thurmon and Benson 1987)
- c) For standing chemical restraint for castrations: Administer acepromazine at 0.088 mg/kg (or 40 mg/450 kg) IV after about 10 minutes when patient is obviously tranquilized, give pentazocine at 0.5 mg/kg (225 mg/450kg) IV and then administer local anesthetic to each cord and the incision sites on ventral surface of the scrotum. (Abrahamsen 2007b)

■ SWINE:

For analgesia:

- a) 2 mg/kg IM q4h as needed (Jenkins 1987)

Monitoring

- Analgesic efficacy
- Respiratory rate/depth
- Appetite/bowel function
- CNS effects

Client Information

- Clients should report any significant changes in behavior, appetite, bowel, or urinary function in their animals.

Chemistry/Synonyms

A synthetic partial opiate agonist, pentazocine is commercially available as two separate salts. The hydrochloride salt, which is found in oral dosage forms, occurs as a white, crystalline powder. It is soluble in water and freely soluble in alcohol. The commercial injection is prepared from pentazocine base with the assistance of lactic acid. This allows the drug to be soluble in water. The pH of this product is adjusted to a range of 4–5. Pentazocine is a weak base with an approximate pK_a of 9.0.

Pentazocine may also be known as: NIH-7958, NSC-107430, pentazocinum, Win-20228, *Talacen*®, and *Talwin*®.

Storage/Stability/Compatibility

The tablet preparations should be stored at room temperature and in tight, light-resistant containers. The injectable product should be kept at room temperature; avoid freezing.

The following agents have been reported to be physically **compatible** when mixed with pentazocine lactate: atropine sulfate, benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, dimenhydrinate, diphenhydramine HCl, droperidol, fentanyl citrate, hydromorphone, hydroxyzine HCl, meperidine HCl, metoclopramide, morphine sulfate, perphenazine, prochlorperazine edisylate, promazine HCl, promethazine HCl, and scopolamine HBr. The following agents have been reported to be physically **incompatible** when mixed with pentazocine lactate: aminophylline, amobarbital sodium, flunixin meglumine, glycopyrrolate, pentobarbital sodium, phenobarbital sodium, secobarbital sodium, and sodium bicarbonate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pentazocine Lactate Injection: 30 mg/mL in 10 mL vials, *Uni-Amps* & amps; 1 mL and 2 mL fill in 2 mL *Carpusject*; *Talwin*® (Abbott Hospital Products); (Rx, C-IV)

Pentazocine HCl and Naloxone HCl Tablets (Scored): 50 mg (as hydrochloride) & 0.5 mg naloxone; *Talwin NX*® (Sanofi Winthrop); generic; (Royce); (Rx, C-IV)

Pentazocine HCl and Aspirin Tablets: 12.5 mg/325 mg aspirin; *Talwin*® Compound (Sanofi Winthrop); (Rx, C-IV)

Pentazocine HCl and Acetaminophen Tablets: 25 mg/650 mg acetaminophen; *Talacen*® (Sanofi Winthrop); generic; (Rx, C-IV)

PENTOBARBITAL SODIUM

(pen-toe-*bar*-bi-tal) Nembutal®

BARBITURATE

Note: Pentobarbital and combinations with pentobarbital (e.g., phenytoin) for euthanasia have a separate monograph listed under Euthanasia Agents

Prescriber Highlights

- Barbiturate used therapeutically as a sedative/anesthetic, & treating intractable seizures; also used for euthanasia
- Contraindications: Known hypersensitivity, severe liver disease, nephritis, or severe respiratory depression (large doses). Caution: Hypovolemia, anemia, borderline hypoadrenal function, or cardiac or respiratory disease. Use with caution in cats (sensitive to respiratory depression).
- Adverse Effects: respiratory depression (if using for anesthesia have ventilatory support available), hypothermia, or excitement post-anesthesia (dogs)
- When giving IV, administer SLOWLY (unless for euthanasia); very irritating if given SC or perivascularly; do not give IA
- Numerous drug interactions

Uses/Indications

Once pentobarbital was the principal agent used for general anesthesia in small animals, but this has been largely supplanted by the use of inhalant anesthetic agents. It is still commonly used as an anesthetic in laboratory situations, for rodents and occasionally as a sedative agent in dogs and cats.

Pentobarbital can be used for treating intractable seizures secondary to convulsant agents (e.g., strychnine) or secondary to CNS toxins (e.g., tetanus). It should not be used to treat seizures caused by lidocaine intoxication. For refractory status epilepticus not controlled with diazepam and phenobarbital, pentobarbital can be used, but propofol is preferred by some as it causes less cardiovascular depression and recoveries can be smoother.

Pentobarbital has been used as a sedative and anesthetic agent in horses, cattle, swine, sheep, and goats. Often the drug is given after a preanesthetic agent in order to reduce pentobarbital dosages and resultant side effects.

Pentobarbital is a major active ingredient in several euthanasia solutions. This indication is discussed in the monograph for Euthanasia Agents.

Pharmacology/Actions

While barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. While the exact mechanisms for the CNS effects caused by barbiturates are unknown, they have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. The barbiturates also have effects on GABA and pentobarbital has been shown to be GABA-mimetic. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced is dependent on the dosage, route of administration, pharmacokinetics of the drug, and species treated. Additionally, effects may be altered by patient age, physi-

cal condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. In humans, it has been shown that barbiturates reduce the rapid-eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates cause a dose-dependent respiratory depression, but, in some species, they can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses four times lower than those will cause cardiac arrest. These drugs must be used very cautiously in cats; they are particularly sensitive to the respiratory depressant effects of barbiturates.

Besides the cardiac arresting effects of the barbiturates at euthanizing dosages, the barbiturates have other cardiovascular effects. In the dog, pentobarbital has been demonstrated to cause tachycardia, decreased myocardial contractility and stroke volume, and decreased mean arterial pressure and total peripheral resistance.

The barbiturates cause reduced tone and motility of the intestinal musculature, probably secondary to its central depressant action. The thiobarbiturates (thiamylal, thiopental) may, after initial depression, cause an increase in both tone and motility of the intestinal musculature; however, these effects do not appear to have much clinical significance. Administration of barbiturates reduces the sensitivity of the motor end-plate to acetylcholine, thereby slightly relaxing skeletal muscle. Because the musculature is not completely relaxed, other skeletal muscle relaxants may be necessary for surgical procedures.

There is no direct effect on the kidney by the barbiturates, but severe renal impairment may occur secondary to hypotensive effects in overdose situations. Liver function is not directly affected when used acutely, but hepatic microsomal enzyme induction is well documented with extended barbiturate (especially phenobarbital) administration. Although barbiturates reduce oxygen consumption of all tissues, no change in metabolic rate is measurable when given at sedative dosages. Basal metabolic rates may be reduced with resultant decreases in body temperature when barbiturates are given at anesthetic doses.

Pharmacokinetics

Pentobarbital is absorbed quite rapidly from the gut after oral or rectal administration with peak plasma concentrations occurring between 30–60 minutes after oral dosing in humans. The onset of action usually occurs within 15–60 minutes after oral dosing and within 1 minute after IV administration.

Pentobarbital, like all barbiturates, distributes rapidly to all body tissues with highest concentrations found in the liver and brain. It is 35–45% bound to plasma proteins in humans. Although less lipophilic than the ultra-short acting barbiturates (e.g., thiopental), pentobarbital is highly lipid soluble and patient fat content may alter the distributive qualities of the drug. All barbiturates cross the placenta and enter milk (at concentrations far below those of plasma).

Pentobarbital is metabolized in the liver principally by oxidation. Excretion of the drug is not appreciably enhanced by increased urine flow or alkalinizing the urine. Ruminants (especially sheep and goats) metabolize pentobarbital at a very rapid rate. The elimination half-life in the goat has been reported to be approximately 0.9 hrs. Conversely, the half-life in dogs is approximately 8 hours; in man, it ranges from 15–50 hours.

Contraindications/Precautions/Warnings

Use cautiously in patients who are hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease. Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction. Barbiturates are contraindicated in patients with severe liver disease or who have demonstrated previous hypersensitivity reactions to them.

When administering IV, give SLOWLY. Use for cesarean section is not recommended because of fetal respiratory depression. Cats tend to be particularly sensitive to the respiratory depressant effects of barbiturates; use with caution in this species. Female cats appear to be more susceptible to the effects of pentobarbital than male cats.

Adverse Effects

Because of the respiratory depressant effects of pentobarbital, respiratory activity must be closely monitored and respiratory assistance must be readily available when using anesthetic dosages. Pentobarbital may cause excitement in dogs during recovery from anesthetic doses. Hypothermia may develop in animals receiving pentobarbital if exposed to temperatures below 27°C (80.6°F). The barbiturates can be very irritating when administered SC or perivascularly; avoid these types of injections. Do not administer intra-arterially.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: *D* (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Exercise caution when administering to the nursing mother, since small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported.

Overdosage/Acute Toxicity

In dogs, the reported oral LD₅₀ is 85 mg/kg and IV LD₅₀ is 40–60 mg/kg. Fatalities from ingestion of meat from animals euthanized by pentobarbital have been reported in dogs. Treatment of pentobarbital overdose consists of removal of ingested product from the gut if appropriate and offering respiratory and cardiovascular support. Forced alkaline diuresis is of little benefit for this drug. Peritoneal or hemodialysis may be of benefit in severe intoxications.

Drug Interactions

Most clinically significant interactions have been documented in humans with phenobarbital; however, these interactions may also be of significance in animals receiving pentobarbital, especially with chronic therapy.

- **ACETAMINOPHEN:** Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are given.
- **LIDOCAINE:** Fatalities have been reported when dogs suffering from lidocaine-induced seizures were treated with pentobarbital. Until this interaction is further clarified, it is suggested that lidocaine-induced seizures in dogs be treated initially with diazepam.
- **PHENYTOIN:** Barbiturates may affect the metabolism of phenytoin, and phenytoin may alter barbiturate levels; monitoring of blood levels may be indicated.
- **RIFAMPIN:** May induce enzymes that increase the metabolism of barbiturates.

The following drugs may increase the effect of pentobarbital:

- **ANTI-HISTAMINES**
- **CHLORAMPHENICOL**
- **OPIATES**
- **PHENOTHIAZINES**
- **VALPROIC ACID**

Pentobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:

- **ANTICOAGULANTS, ORAL (WARFARIN)**
- **BETA-BLOCKERS**
- **CHLORAMPHENICOL**
- **CLONAZEPAM**
- **CORTICOSTEROIDS**
- **CYCLOSPORINE**
- **DOXORUBICIN**
- **DOXYCYCLINE** (may persist for weeks after barbiturate discontinued)
- **ESTROGENS**
- **GRISEOFULVIN**
- **METHADONE**
- **METRONIDAZOLE**
- **QUINIDINE**
- **PAROXETINE**
- **PHENOTHIAZINES**
- **PROGESTINS**
- **THEOPHYLLINE**
- **TRICYCLIC ANTIDEPRESSANTS**
- **VERAPAMIL**

Laboratory Considerations

- Barbiturates may cause increased retention of **bromosulfophthalein** (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests.

Doses

Note: In order to avoid possible confusion, doses used for euthanasia are listed separately under the monograph for euthanasia solutions.

■ DOGS:

As a sedative:

- a) 2–4 mg/kg IV (Kirk 1986)
- b) 2–4 mg/kg PO q6h (Davis 1985a)

For anesthesia:

- a) 30 mg/kg IV to effect (Kirk 1986)
- b) 10–30 mg/kg IV to effect (Morgan 1988)
- c) 24–33 mg/kg IV (Booth 1988a)

For chemical restraint for ventilatory support:

- a) 4 mg/kg initially IV; then 2–4 mg/kg/hr thereafter [Given concomitantly with oxymorphone: 0.2 mg/kg (up to 4.5 mg) IV; then 0.1 mg/kg every 2 hours thereafter] (Pascoe 1986)

For post-myelographic seizures:

- a) 2–4 mg/kg IV (to effect) (Walter, Feeney, and Johnston 1986)

For status epilepticus:

- a) Give to effect and not as a specific dose. Dose range is 3–15 mg/kg IV. (Platt and McDonnell 2000)
- b) 3–15 mg/kg IV SLOWLY to effect. Goal is heavy sedation, not surgical planes of anesthesia. May need to repeat in 4–8 hours. (Raffe 1986)

■ CATS:

As a sedative:

- a) 2–4 mg/kg IV (Kirk 1986)
- b) 2–4 mg/kg PO q6h (Davis 1985a)

For status epilepticus:

- a) 5–15 mg/kg IV to effect (Morgan 1988)
- b) 3–15 mg/kg IV SLOWLY to effect. Goal is heavy sedation, not surgical planes of anesthesia. May need to repeat in 4–8 hours. (Raffe 1986)

For anesthesia:

- a) 25 mg/kg IV, an additional 10 mg/kg IV may be given if initial dose is inadequate (Booth 1988a)

■ SMALL MAMMALS/RODENTS:

For chemical restraint:

- Mice: 30–80 mg/kg IP
- Rats: 40–60 mg/kg IP
- Hamsters/Gerbils: 70–80 mg/kg IP
- Guinea pig: 15–40 mg/kg IP; 30 mg/kg IV
- Rabbits: 20–60 mg/kg IV (Burke 1999)

■ CATTLE:

- a) 30 mg/kg IV to effect, repeat as needed for chlorinated hydrocarbon toxicity (Smith 1986)
- b) As an anesthetic in calves (over one month of age): 15–30 mg/kg IV (Thurmon and Benson 1986)
- c) As a sedative: 1–2 grams IV in an adult cow (given until animal becomes unsteady and rear limb weakness occurs). 3 grams will usually induce recumbency. (Thurmon and Benson 1986)

■ HORSES:

Note: Pentobarbital is generally not considered an ideal agent for use in the adult horse due to possible development of excitement and injury when the animal is “knocked down.” (**Note:** ARCI UCGFS Class 2 Drug)

- a) 3–15 mg/kg IV (Robinson 1987)
- b) 15–18 mg/kg IV for light anesthesia (Schultz 1986)

■ SWINE:

- a) 30 mg/kg IV to effect (Howard 1986)
- b) As an anesthetic: 15–30 mg/kg IV (Thurmon and Benson 1986)

■ SHEEP:

As an anesthetic:

- a) 20–30 mg/kg IV (Thurmon and Benson 1986)
- b) Adult Sheep: 11–54 mg/kg IV (average dose 24 mg/kg IV). Anesthesia required for longer than 15–30 minutes will require additional doses.
Lambs: 15–26 mg/kg IV (will induce anesthesia for 15 minutes). Additional 5.5 mg/kg IV will give another 30 minutes of effect. (Booth 1988a)

■ GOATS:

As an anesthetic:

- a) 20–30 mg/kg IV (Thurmon and Benson 1986)
- b) 25 mg/kg IV slowly, duration of satisfactory anesthesia will last only 20 minutes or so. (Booth 1988a)

Monitoring

- Levels of consciousness and/or seizure control
- Respiratory and cardiac signs
- Body temperature
- If using chronically, routine blood counts and liver function tests should be performed.

Client Information

- This drug is best used in an inpatient setting or with close professional supervision.
- If dosage forms are dispensed to clients, they must be in instructed to keep them away from children; dispense in child-resistant packaging.

Chemistry/Synonyms

Pentobarbital sodium occurs as odorless, slightly bitter tasting, white, crystalline powder or granules. It is very soluble in water and freely soluble in alcohol. The pK_a of the drug has been reported to range from 7.85–8.03 and the pH of the injection is from 9–10.5. Alcohol or propylene glycol may be added to enhance the stability of the injectable product.

Pentobarbital may also be known as: aethaminalum, mebubarbital, mebumal, pentobarbitalum, or pentobarbitone.

Storage/Stability/Compatibility

The injectable product should be stored at room temperature; the suppositories should be kept refrigerated. The aqueous solution is not very stable and should not be used if it contains a precipitate. Because precipitates may occur, pentobarbital sodium should not be added to acidic solutions.

The following solutions and drugs have been reported to be physically **compatible** with pentobarbital sodium: dextrose IV solutions, Ringer's injection, lactated Ringer's injection, Saline IV solutions, dextrose-saline combinations, dextrose-Ringer's combinations, dextrose-Ringer's lactate combinations, amikacin sulfate, aminophylline, atropine sulfate (for at least 15 minutes, not 24 hours), calcium chloride, cephapirin sodium, chloramphenicol sodium succinate, hyaluronidase, hydromorphone HCl, lidocaine HCl, neostigmine methylsulfate, scopolamine HBr, sodium bicarbonate, sodium iodide, thiopental sodium, and verapamil HCl.

The following drugs have been reported to be physically **incompatible** with pentobarbital sodium: benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, cimetidine HCl, chlorpheniramine maleate, codeine phosphate, diphenhydramine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydrocortisone sodium succinate, hydroxyzine HCl, insulin (regular), meperidine HCl, nalbuphine HCl, norepinephrine bitartrate, oxytetracycline HCl, penicillin G potassium, pentazocine lactate, phenytoin sodium, prochlorperazine edisylate, promazine HCl, promethazine HCl, and streptomycin sulfate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pentobarbital Sodium Injection: 50 mg/mL in 2 mL *Tubex*; generic; (Wyeth-Ayerst); (Rx, C-II)

Pentobarbital is a Class-II controlled substance and detailed records must be maintained with regard to its use and disbursement.

PENTOSAN POLYSULFATE SODIUM

(*pen-toe-san*) PPS, Cartrophen-Vet®, Elmiron®

ANTIINFLAMMATORY, OSTEOARTHRITIS DISEASE-MODIFIER

Prescriber Highlights

- May be useful in treating osteoarthritis in dogs, cats & horses; may be used as adjunctive treatment of feline interstitial cystitis (feline idiopathic lower urinary tract disease—FLUTD)
- Efficacy for FLUTD not well-documented
- Adverse effects uncommon, but can cause bleeding, GI effects
- Use with caution prior to surgery or with other drugs affecting coagulation
- In the USA, only human oral product available; may be expensive

Uses/Indications

Pentosan may be useful in treating osteoarthritis in dogs, cats, and horses. It has been used as an adjunctive treatment of feline interstitial cystitis (feline idiopathic lower urinary tract disease—FLUTD). Studies using pentosan for FLUTD have demonstrated that it is not effective for short-term, acute lower urinary tract disease, but some patients may benefit when it is used for chronic, persistent signs associated with FLUTD.

Pharmacology/Actions

Pentosan has a mild analgesic effect when used for interstitial cystitis. The mechanism for its action in treating interstitial cystitis is not known, but it is postulated that it may adhere to bladder wall mucosal membranes and act as a “buffer” to prevent irritating compounds in urine from reaching bladder cells.

Pentosan has disease-modifying effects on osteoarthritic joints similar to polysulfated glycosaminoglycans. It apparently modulates cytokine action, preserves preteoglycan content and stimulates hyaluronic acid synthesis. Pentosan has antiinflammatory, hypolipidemic, anticoagulant (considerably weaker than heparin—1/15th), and fibrinolytic properties. These effects potentially could increase synovial blood flow and reduce joint inflammation.

Pharmacokinetics

In rats, 10–20% of the calcium derivative (pentosan polysulfate calcium) is absorbed after oral dosing. In humans, only about 3% of an oral dose of pentosan polysulfate sodium is absorbed. It distributes primarily to the uroepithelium of the genitourinary tract with smaller concentrations found in the liver, spleen, lung skin, bone marrow, and periosteum. About two-thirds of absorbed drug is desulfated in the liver and spleen within one hour; about 3.5% of the absorbed drug is excreted into the urine.

Contraindications/Precautions/Warnings

Pentosan is contraindicated in patients hypersensitive to it. Use this drug with caution in animals also receiving other medications that can affect coagulation, or having surgery in the near future.

Adverse Effects

Pentosan is usually well tolerated. Adverse effects of pentosan in veterinary species appear to be mild and transitory in nature. In dogs, vomiting, anorexia, lethargy, or mild depression are possible. When used orally in cats, pentosan seems to be tolerated well, but oral dosing twice daily can be stressful for both cat and owner. Because pentosan has some anticoagulant effects, bleeding is possible in any species and may be more likely in animals receiving other drugs that affect coagulation (e.g., aspirin), or undergoing stressful exercise. In horses, pentosan causes dose-dependent increases in partial thromboplastin time (PTT) up to 24 hours post-dose. In a small percentage of humans (<2%) taking the medication, transient increases in liver enzymes have been reported.

Reproductive/Nursing Safety

In humans, pentosan is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Pentosan is likely safe to use during nursing.

Overdosage/Acute Toxicity

Information regarding overdoses is not readily available. Potentially, overdoses could cause bleeding, thrombocytopenia, GI distress, and liver function abnormalities. At the present time, treatment recommendations are basically supportive in nature. If an oral overdose occurs, consider protocols for drug removal from the gut.

Drug Interactions

No specific drug interactions were located; use this drug cautiously with other **drugs that can affect coagulation** (e.g., NSAIDs, aspirin, heparin, etc.).

Laboratory Considerations

No laboratory interactions or considerations were noted

Doses

■ DOGS:

As a chondroprotective for osteoarthritis (OA):

- High loading dose: 20 mg/kg PO twice weekly for 5 weeks (for treatment of OA signs of pain, lameness and stiffness); Medium Loading dose: 10 mg/kg PO once weekly for 12 weeks (for management of OA after joint surgery); Maintenance dose: 10 mg/kg once weekly for 4 weeks as needed. Always give on an empty stomach. (Label information; *Cartrophen-Vet® Capsules*—Arthroparm)
- 3 mg/kg IM or SC on four occasions with an interval of 5–7 days between injections (Label information; *Pentosan 100® Injection* —Nature Vet)

■ CATS:

For treatment of persistent or recurrent FLUTD:

- 2–16 mg/kg PO q12h (Bartges 2002b)
- 8 mg/kg PO q12h (Lane 2002a)

■ HORSES:

For treating osteoarthritis:

- Intramuscular administration: 3 mg/kg IM on four occasions with an interval of 7 days between injections.
Intra-articular injection: Prepare site as for surgery. Avoid iodine based skin preps; use a neutral soapless skin cleanser. A 20 g non-cutting needle is preferred. Introduce into joint space with steady, even pressure. Allow approximately 1 mL of synovial fluid to escape. Attach syringe with pentosan into

the syringe and withdraw more synovial fluid to enter syringe, if possible. Inject mixture back into joint; draw back once or twice to mix pentosan and joint fluid within the joint. Firmly bandage and confine for 3–4 hours, then remove bandage. Rest horse for 2 weeks and follow with another 2 weeks of graded walking exercise before returning to work. (Label information; *Pentosan Equine® Injection*—Nature Vet)

Monitoring

- When used for veterinary indications clinical efficacy is the primary monitoring parameter.
- When administered into joints, animals should be assessed for intra-articular bleeding.

Client Information

- In cats, pentosan (human product) is usually dosed at 1/2 capsule (50 mg) twice daily. One half the contents of a commercially available capsule may be emptied into an empty gelatin capsule and administered.
- Give oral medication on an empty stomach

Chemistry/Synonyms

A heparin-like compound, pentosan polysulfate sodium is a mixture of linear polymers of beta-1->4-linked xylose that are usually sulfated at the 2- and 3- positions. Average molecular weight is between 4000 and 6000. It is not derived from animal sources, but from Beechwood hemicellulose.

Pentosan may also be known as: pentosan polysulphate sodium; PZ-68; sodium pentosan polysulphate; sodium xylanpolysulphate; SP-54, *Cartrophen-Vet®*, *Fibrase®*, *Fibrezym®*, *Fibrocid®*, *Fibrocide®*, *Hemoclar®*, *Lelong Contusions®*, *Elmiron®*, *Pentosan®*, *Polyanion®*, *Tavan®-SP 54*, and *Thrombocid®*.

Storage/Stability

Unless otherwise labeled, store oral pentosan products at controlled room temperature (15–30°C; 59–86°F) and injectable pentosan products under refrigeration and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No products currently available in USA.

In several other countries, *Cartrophen-Vet®* is available as oral 100 mg capsules (pentosan polysulfate calcium) labeled for use in dogs. Injectable pentosan polysulfate sodium 100mg/mL (*Pentosan 100® Injection*, and *Cartrophen-Vet® Injection*) labeled for use in dogs and pentosan polysulfate sodium 250 mg/mL (*Pentosan Equine® Injection*) for horses are available in several countries.

HUMAN-LABELED PRODUCTS:

Pentosan Polysulfate Sodium Capsules: 100 mg; *Elmiron®* (Baker Norton); (Rx)

PENTOXIFYLLINE

(pen-tox-ih-fi-leen) PTX, Trental®

HEMORRHEOLOGIC, IMMUNOMODULATORY AGENT

Prescriber Highlights

- ▶ Compound that increases erythrocyte flexibility & may decrease negative effects of endotoxemia
- ▶ Contraindications: Retinal or cerebral hemorrhage, intolerant or hypersensitive to it or other xanthines (*i.e.*, theophylline)
- ▶ Caution: Severe hepatic or renal impairment, or at risk for hemorrhage
- ▶ Adverse Effects: GI tract (vomiting/inappetence) most common. Potentially: Dizziness, other GI, CNS, or cardiovascular effects

Uses/Indications

In horses, pentoxifylline has been used as adjunctive therapy for cutaneous, vasculitis, endotoxemia and for the treatment of navicular disease.

Pentoxifylline has been used in dogs to treat immune-mediated dermatologic conditions, enhance healing, and reduce inflammation caused by ulcerative dermatosis in Shelties and Collies and for other conditions where improved microcirculation may be of benefit. It is being investigated for adjunctive therapy for dilated cardiomyopathy in Doberman pinschers.

Pentoxifylline has been tried in conjunction with prednisolone to decrease vasculitis associated with FIP in cats.

Pentoxifylline's major indications for humans include symptomatic treatment of peripheral vascular disease (*e.g.*, intermittent claudication, sickle cell disease, Raynaud's, etc.) and cerebrovascular diseases where blood flow may be impaired in the microvasculature.

Pharmacology/Actions

The mechanisms for pentoxifylline's actions are not fully understood. The drug increases erythrocyte flexibility probably by inhibiting erythrocyte phosphodiesterase and decreases blood viscosity by reducing plasma fibrinogen and increasing fibrinolytic activity.

Pentoxifylline is postulated to reduce negative endotoxemic effects of cytokine mediators via its phosphodiesterase inhibition.

Pharmacokinetics

In horses, after PO administration of crushed, sustained-release tablets, pentoxifylline is rapidly absorbed with a wide interpatient variation of bioavailability that averages around 68%. Bioavailability may decrease with continued administration over several days. The authors concluded that 10 mg/kg q12h PO yields serum levels equivalent to those observed after administration of therapeutic doses to humans and horses.

In dogs, pentoxifylline reportedly has a bioavailability of approximately 50% with peak levels occurring about 1–3 hours after dosing. Serum half-life is approximately 6–7 hours for the parent compound, 36 hours for active metabolite 1, and 8 hours for active metabolite 5.

In humans, pentoxifylline absorption from the gastrointestinal tract is rapid and almost complete, but a significant first-pass effect occurs. Food affects the rate, but not the extent, of absorption. While the distributive characteristics have not been fully described, it is known that the drug enters maternal milk. Pentoxifylline is me-

tabolized both in the liver and erythrocytes; all identified metabolites appear to be active.

Contraindications/Precautions/Warnings

Pentoxifylline should be considered contraindicated in patients who have been intolerant to the drug or xanthines (*e.g.*, theophylline, caffeine, theobromine) in the past and those with cerebral hemorrhage or retinal hemorrhage. It should be used cautiously in patients with severe hepatic or renal impairment and those at risk for hemorrhage.

Adverse Effects

Most commonly reported adverse effects involve the GI tract (vomiting/inappetence) or CNS (excitement, nervousness). Erythema multiforme may occur rarely, secondary to pentoxifylline therapy in dogs.

In horses, IV administration may be associated with transient leukocytosis, muscle fasciculations, sweating on shoulders and flanks, and mild increases in heart rate. Oral dosing at 10 mg/kg or less appears to be well tolerated.

There are reports of dizziness and headache occurring in a small percentage of humans receiving the drug. Other adverse effects, primarily GI, CNS, and cardiovascular related, have been reported in people, but are considered to occur rarely. Veterinary experience is limited with pentoxifylline and animal adverse effects may differ.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Pentoxifylline may be teratogenic at high dosages.

Pentoxifylline and its metabolites are excreted in maternal milk. Because of the potential for tumorigenicity (seen in rats), use cautiously in nursing patients.

Overdosage/Acute Toxicity

Humans overdosed with pentoxifylline have demonstrated signs of flushing, seizures, hypotension, unconsciousness, agitation, fever, somnolence, GI distress and ECG changes. One patient who ingested 80 mg/kg recovered completely. Overdoses should be treated using the usual methods of appropriate gut emptying and supportive therapies.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pentoxifylline and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS:** With pentoxifylline may increase hypotensive effect
- **NSAIDS:** Use of non-steroidal antiinflammatory agents with pentoxifylline in horses is controversial. Some sources state that when used for endotoxemia in horses, pentoxifylline's beneficial effects are negated by NSAIDs, but one study showed superior efficacy when flunixin and pentoxifylline were used together, compared with either used alone.
- **PLATELET-AGGREGATION INHIBITORS** (*e.g.*, aspirin, clopidogrel): Increased risk for bleeding
- **THEOPHYLLINE:** Serum levels may be increased when used concurrently with pentoxifylline
- **WARFARIN:** When pentoxifylline is used with warfarin or other anticoagulants, increased risk of bleeding may result; use together with enhanced monitoring and caution

Doses

■ DOGS:

- For dermatologic conditions (e.g., dermatomyositis, ear margin seborrhea/necrosis, ulcerative dermatitis of collies/shelties, contact dermatitis, atopy and any disease with underlying vasculitis): 10 mg/kg PO q8h, if the disease does not respond, 15 mg/kg PO q8h may be effective (Merchant 2000)
- 10 mg/kg PO 2–3 times daily (Marsella 1999)
- For dermatologic disorders including dermatomyositis, vasculitis, erythema multiforme, cutaneous and renal vasculitis of Greyhounds (Alabama rot), and allergic contact dermatitis: 10–30 mg/kg PO q 12 hours (Campbell 1999)
- For familial canine dermatomyositis: 25 mg/kg PO q12h appears to be an effective beginning dose (Rees and Boothe 20003)
- For atopic dermatitis: 10–15 mg/kg PO q8–12h. A 6–8 week course of therapy may be required to assess efficacy. (White 2003d)
- For vasculitis, dermatomyositis: 10 mg/kg PO q8h (Boord 2007)
- For vasculitis: 15 mg/kg PO q8h (Hillier 2006d)

■ CATS:

To reduce vasculitis in cats with FIP:

- 100 mg per cat PO twice daily (with prednisolone at 2–4 mg/kg/day PO; taper every two weeks).

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- 10 mg/kg q12h PO yields serum levels equivalent to those observed after administration of therapeutic doses to humans and horses. OK to crush the sustained-release tablets and mix with molasses. If efficacy wanes with time, consider increasing the dose to 15 mg/kg PO twice daily or 10 mg/kg PO three times a day. In the experience of the authors, 10 mg/kg PO twice daily for 30 days results in clinical response in horses with cutaneous vasculitis. (Liska, Akucowich et al. 2006)

To reduce cytokine effects in endotoxemia:

- 7.5 mg/kg PO q12h, efficacy may be improved if used with flunixin (Smith 2003b)
- 8 mg/kg PO q8h (Barton 2003)

For adjunctive treatment of equine pastern dermatitis:

- If clinical signs do not resolve after 14 days of topical and other immunomodulating therapy, add pentoxifylline at 4–8 mg/kg PO q12h (Yu 2003)

For adjunctive treatment of navicular disease:

- 6 grams per day PO for 6 weeks (Livesay 1996)

To increase oxygenation of placenta in placentitis:

- 7.5 mg/kg PO q12h (Troedsson 2003)

To increase the circulation to the podotrochlea:

- 4.5–7 mg/kg PO three times daily (Turner 1999)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Give with food to reduce the GI effects of pentoxifylline
- Clients should understand that veterinary experience with this medication is limited and that the risk versus benefit profile is not well-defined

Chemistry/Synonyms

A synthetic xanthine derivative structurally related to caffeine and theophylline, pentoxifylline occurs as a white, odorless, bitter-tasting, crystalline powder. At room temperature, approximately 77 mg are soluble in one mL of water and 63 mg in one mL of alcohol.

Pentoxifylline may also be known as: BL-191, oxpentifylline, or pentoxifyllinum and *Trental*®.

Storage/Stability

The commercially available tablets should be stored in well-closed containers, protected from light at 15–30°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pentoxifylline Controlled/Extended Release Tablets: 400 mg; *Trental*® (Hoechst Marion Roussel); generic; (Purepac); (Rx)

PERGOLIDE MESYLATE

(per-go-lide) Permax®

DOPAMINE AGONIST

Prescriber Highlights

- Dopamine agonist that can help control signs associated with equine Cushing's disease
- Apparently, very well tolerated in horses
- May be significant expense involved, since treatment is life-long
- Commercial availability an issue; may need to obtain via compounding pharmacies

Uses/Indications

The primary use for pergolide in veterinary medicine is in treatment of horses for pituitary pars intermedia dysfunction (PPID), commonly called equine Cushing's disease.

Pharmacology/Actions

Pergolide is a potent agonist at dopamine receptors D₁ and D₂ and is 10–1000 times more potent than bromocriptine. It is thought that pituitary pars intermedia dysfunction (PPID) in horses is a dopaminergic degenerative disease and pergolide (or dopamine) can reduce expression of proopiomelanocortin (POMC) peptides from the pars intermedia. These peptides are implicated in causing the signs associated with PPID.

Pharmacokinetics

No information on pergolide pharmacokinetics in horses was located. In humans, the drug is orally absorbed (estimated 60% bio-available) and is 90% bound to plasma proteins. At least 10 different metabolites have been identified, some of which are active. The principle route of elimination is via the kidneys.

Contraindications/Precautions

Pergolide is contraindicated in patients hypersensitive to it or other ergot derivatives.

Adverse Effects

Pergolide appears to be very well tolerated in horses. Adverse effects reported in humans include: nervous system complaints (dyskinesia, hallucinations, somnolence and insomnia), gastrointestinal complaints (nausea, vomiting, diarrhea, constipation), transient hypotension, and rhinitis.

Reproductive/Nursing Safety

Safety of pergolide in pregnant horses has not been established. In humans, pergolide is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known if pergolide enters maternal milk; however, like other ergot-derivative dopamine agonists, it may interfere with actation.

Overdosage/Acute Toxicity

There is limited information available on pergolide overdoses. Potential effects include GI disturbances, CNS effects, seizures, and hypotension.

There were 15 exposures to pergolide mesylate reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. All of these 15 reported cases were dogs with 6 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, depression, hyperactivity, and hypertension.

Treatment is supportive. Phenothiazines may decrease CNS stimulation effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pergolide and may be of significance in veterinary patients:

- **DOPAMINE ANTAGONISTS** (*i.e.*, **phenothiazines**): May decrease the effects of pergolide
- **METOCLOPRAMIDE**: May decrease the effects of pergolide

Laboratory Considerations

No specific laboratory interactions or considerations were noted for this drug.

Doses■ **HORSES:**

For treatment of Equine “Cushing’s-like” Disease [pituitary pars intermedia dysfunction (PPID)]:

- a) Initial dose is usually 0.5 mg per day. Reassess at 4–8 weeks by means of dexamethasone suppression test and blood glucose (if hyperglycemia was present prior to treatment). If not normal, increase dose in 0.25 mg increments and reassess as above. Most horses respond clinically in 6 weeks and usually at 0.75–1.25 mg per day. Treatment must be continued for life. (Dybdal 1997)

Monitoring

- Dexamethasone suppression test (baseline and at 4–8 weeks post pergolide therapy initiation, repeat in 4–8 weeks if dosage is adjusted)
- Blood glucose (baseline, and if abnormal and repeat as per dexamethasone suppression test)
- Clinical signs (hair coat, weight, PU/PD, etc.)
- Periodic CBC and clinical chemistry panel

Client Information

- Clients should understand that pergolide does not cure the disease and it may take several weeks to months to see efficacy.
- Treatment is required for the life of the horse and the drug can be expensive.
- Proper nutrition and weight control can be very important to the successful treatment of this disease.

Chemistry/Synonyms

An ergot derivative, dopamine receptor agonist, pergolide occurs as white to off-white powder that is slightly soluble in water, dehydrated alcohol, or chloroform. It is very slightly soluble in acetone; practically insoluble in ether and sparingly soluble in methyl alcohol.

Pergolide mesylate may also be known as: LY-127809, pergolide mesilate, pergolide mesilas, *Celance*®, *Nopar*®, *Parkotil*®, *Parlide*®, or *Pharken*®.

Storage/Stability

Store pergolide tablets in tight containers at room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Due to an increased potential for heart valve damage associated with pergolide use in humans, all dosage forms were withdrawn from the US market in the Spring of 2007. Pergolide may be available from compounding pharmacies for veterinary use.

PHENOBARBITAL SODIUM PHENOBARBITAL

(fee-noe-bar-bi-tal)

BARBITURATE

Prescriber Highlights

- ▶ Barbiturate used primarily as an antiseizure medication; also used as a sedative agent
- ▶ Contraindications: Known hypersensitivity, severe liver disease, nephritis, or severe respiratory depression (large doses)
- ▶ Caution: Hypovolemia, anemia, borderline hypoadrenal function, or cardiac or respiratory disease; use with caution in cats (sensitive to respiratory depression)
- ▶ Adverse Effects: DOGS: Anxiety/agitation or lethargy (when initiating treatment); profound depression, (even at low doses) is possible. Sedation, ataxia, polydipsia, polyuria, polyphagia can be seen at moderate to high serum levels. Increase in liver enzymes possible, but overt hepatotoxicity relatively uncommon. Rare: Anemia, thrombocytopenia or neutropenia.
- ▶ Adverse Effects: CATS: Ataxia, lethargy, polyphagia/weight gain & polydipsia/polyuria. Rare: Immune-mediated reactions & bone marrow hypoplasia
- ▶ When administering IV, give SLOWLY; do not give SC or perivascularly (very irritating)
- ▶ Drug Interactions; drug-lab interactions
- ▶ C-IV controlled substance

Uses/Indications

Although some believe that bromide salts are now the treatment of first choice for treating epilepsy in dogs (especially young dogs and those with liver disease), many still choose phenobarbital for dogs because of its favorable pharmacokinetic profile, relative safety, efficacy, low cost, and ability to treat epilepsy at sub-hypnotic doses. Phenobarbital is still widely considered the drug of first choice for treating epilepsy in cats. It is also occasionally used as an oral sedative agent in both species. Because it has a slightly longer onset of action, it is used principally in the treatment of status epilepticus in dogs, cats, and horses to prevent the recurrence of seizures after they have been halted with either a benzodiazepine or short-acting barbiturate. Phenobarbital may also be useful in controlling excessive feline vocalization while riding in automobiles.

In cattle, the microsomal enzyme stimulating properties of phenobarbital has been suggested for its use in speeding the detoxification of organochlorine (chlorinated hydrocarbon) insecticide poisoning. Additionally, phenobarbital has been used in the treatment and prevention of neonatal hyperbilirubinemia in human infants. It is unknown if hyperbilirubinemia is effectively treated in veterinary patients with phenobarbital.

Pharmacology/Actions

While barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. While the exact mechanisms for the CNS effects caused by barbiturates are unknown, they have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. The barbiturates also have effects on GABA and pento-

barbital has been shown to be GABA-mimetic. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced is dependent on the dosage, route of administration, pharmacokinetics of the drug, and species treated. Additionally, effects may be altered by patient age, physical condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. In humans, it has been shown that barbiturates reduce the rapid-eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates cause a dose-dependent respiratory depression, but, in some species, they can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses four times lower than those will cause cardiac arrest. These drugs must be used very cautiously in cats; they are particularly sensitive to the respiratory depressant effects of barbiturates.

The barbiturates cause reduced tone and motility of the intestinal musculature, probably secondary to its central depressant action. Administration of barbiturates reduces the sensitivity of the motor endplate to acetylcholine, thereby slightly relaxing skeletal muscle. Because the musculature is not completely relaxed, other skeletal muscle relaxants may be necessary for surgical procedures.

There is no direct effect on the kidney by the barbiturates, but severe renal impairment may occur secondary to hypotensive effects in overdose situations. Liver function is not directly affected when used acutely, but hepatic microsomal enzyme induction is well documented with extended barbiturate (especially phenobarbital) administration. Although barbiturates reduce oxygen consumption of all tissues, no change in metabolic rate is measurable when given at sedative dosages. Basal metabolic rates may be reduced with resultant decreases in body temperature when barbiturates are given at anesthetic doses.

Pharmacokinetics

The pharmacokinetics of phenobarbital have been thoroughly studied in humans and in a more limited fashion in dogs, cats, and horses. Phenobarbital is slowly absorbed from the GI tract. Bioavailabilities range from 70–90% in humans, approximately 90% in dogs, and absorption is practically complete in adult horses. Peak levels occur in 4–8 hours after oral dosing in dogs, and in 8–12 hours in humans.

Phenobarbital is widely distributed throughout the body, but because of its lower lipid solubility, it does not distribute as rapidly as most other barbiturates into the CNS. The amount of phenobarbital bound to plasma proteins has been reported to be 40–50%. The reported apparent volumes of distribution are approximately: Horse ≈ 0.8 L/kg; Foals ≈ 0.86 L/kg; Dogs ≈ 0.75 L/kg.

The drug is metabolized in the liver primarily by hydroxylated oxidation to p-hydroxyphenobarbital; sulfate and glucuronide conjugates are also formed. The elimination half-lives reported in humans range from 2–6 days; in dogs from 12–125 hours with an average of approximately 2 days. Because of its ability to induce the hepatic enzymes used to metabolize itself (and other drugs), elimination half-lives may decrease with time along with concomitant reductions in serum levels. Some dogs may have half-lives of less than 24 hours and may require 3 times daily dosing for maximal control. An elimination half-life of 34–43 hours has been reported in cats. Elimination half-lives in horses are considerably shorter with values reported of approximately 13 hours in foals and 18 hours in adult horses. Phenobarbital will induce hepatic microsomal enzymes

and it can be expected that elimination half-lives will decrease with time. Approximately 25% of a dose is excreted unchanged by the kidney. Alkalinizing the urine and/or substantially increasing urine flow will increase excretion rates. Anuric or oliguric patients may accumulate unmetabolized drug; dosage adjustments may need to be made.

Changes in diet, body weight, and body composition may alter the pharmacokinetics of phenobarbital in dogs and necessitate dosage adjustment.

Contraindications/Precautions/Warnings

Use cautiously in patients that are hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease. Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction. Barbiturates are contraindicated in patients with severe liver disease or who have demonstrated previous hypersensitivity reactions to them.

When administering IV, give slowly (not more than 60 mg/minute); too rapid IV administration may cause respiratory depression. Commercially available injectable preparations (excluding the sterile powder) must not be administered subcutaneously or perivascularly as significant tissue irritation and possible necrosis may result. Applications of moist heat and local infiltration of 0.5% procaine HCl solution have been recommended to treat these reactions.

Adverse Effects

Dogs may exhibit increased clinical signs of anxiety/agitation or lethargy when initiating therapy. These effects are generally transitory in nature. Occasionally dogs will exhibit profound depression at lower dosage ranges (and plasma levels). Polydipsia, polyuria, and polyphagia are also quite commonly displayed at moderate to high serum levels and may falsely infer a diagnosis of Cushing's disease; these signs are usually controlled by limiting intake of both food and water. Sedation and/or ataxia often become significant concerns as serum levels reach the higher ends of the therapeutic range. Rarely, anemia, thrombocytopenia or neutropenia may occur which are reversible if detected early. Increases in liver enzymes are well described for phenobarbital in dogs and are not necessarily indicative of liver dysfunction, but if serum ALT or ALP are greater than 4–5 times the upper limit of normal, or if any elevation of AST and GGT are noted, it should raise concern. Phenobarbital should generally be discontinued if any increases in serum bilirubin, total serum bile acids or hypoalbuminemia are seen. Frank hepatic failure is uncommon and is usually associated with higher serum levels (>30–40 mcg/mL).

Phenobarbital may rarely cause superficial necrolytic dermatitis (SND) in dogs associated with changes in hepatocytes (severe parenchymal collapse with glycogen-laden hepatocytes and moderate fibrosis sharply demarcated by nodules of normal hepatic parenchyma) distinct from that seen with phenobarbital hepatotoxicity.

Cats may develop ataxia, persistent sedation and lethargy, polyphagia/weight gain, and polydipsia/polyuria. Rarely, immune-mediated reactions and bone marrow hypoplasia (thrombocytopenia, neutropenia) may be seen. Cats, unlike dogs, apparently do not have the issues of increased liver enzymes. Very high dosages (10–40 mg/kg/day) have caused coagulopathies in cats.

Although there is much less information regarding its use in horses (and foals in particular), it would generally be expected that adverse effects would mirror those seen in other species.

Reproductive/Nursing Safety

Phenobarbital has been associated with rare congenital defects and bleeding problems in newborns, but may be safer than other anticonvulsants. In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal*

risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: *B* (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Exercise caution when administering to a nursing mother since small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported.

Overdosage/Acute Toxicity

There were 346 exposures to phenobarbital reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 304 were dogs with 54 showing clinical signs and the remaining 42 reported cases were cats with 10 showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, sedation, lethargy, coma and recumbency. Common findings in cats recorded in decreasing frequency included vomiting, ataxia, mydriasis, sedation, blindness and central nervous system depression.

Treatment of a phenobarbital overdose consists of removal of ingested product from the gut, if appropriate, and giving respiratory and cardiovascular support. Activated charcoal has been demonstrated to be of considerable benefit in enhancing the clearance of phenobarbital, even when the drug was administered parenterally. Charcoal acts as a “sink” for the drug to diffuse from the vasculature back into the gut. Forced alkaline diuresis can also be of substantial benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal dialysis or hemodialysis may be helpful in severe intoxications or in anuric patients.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenobarbital and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are given
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly selegiline): May prolong phenobarbital effects
- **PHENYTOIN:** Barbiturates may affect the metabolism of phenytoin, and phenytoin may alter barbiturate levels; monitoring of blood levels may be indicated
- **RIFAMPIN:** May induce enzymes that increase the metabolism of barbiturates

The following drugs may increase the effects of phenobarbital:

- **ANTIHISTAMINES**
- **CHLORAMPHENICOL**
- **OPIATES**
- **PHENOTHIAZINES**
- **VALPROIC ACID**

Phenobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:

- **ANTICOAGULANTS, ORAL (WARFARIN)**
- **BETA-BLOCKERS**
- **CHLORAMPHENICOL**
- **CLONAZEPAM**
- **CORTICOSTEROIDS**
- **CYCLOSPORINE**
- **DOXORUBICIN**
- **DOXYCYCLINE** (may persist for weeks after barbiturate discontinued)

- **ESTROGENS**
- **GRISEOFULVIN**
- **METHADONE**
- **METRONIDAZOLE**
- **QUINIDINE**
- **PAROXETINE**
- **PHENOTHIAZINES**
- **PROGESTINS**
- **THEOPHYLLINE**
- **TRICYCLIC ANTIDEPRESSANTS**
- **VERAPAMIL**

Laboratory Considerations

- Barbiturates may cause increased retention of **bromosulfophthalein** (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests; or, if they must, (e.g., for seizure control) the results be interpreted accordingly.
- Phenobarbital can alter **thyroid** testing. Decreased total and free T4, normal T3, and either normal or increased TSH have been reported. It has been suggested to wait at least 4 weeks after discontinuing phenobarbital to perform thyroid testing.
- In some dogs, phenobarbital may cause a false positive low dose **dexamethasone suppression test**, by increasing the clearance of dexamethasone. Phenobarbital apparently has no effect either on ACTH stimulation tests or on the hormonal equilibrium of the adrenal axis.

Doses

■ **DOGS:**

For treatment of idiopathic epilepsy:

- a) Initial oral dose: 2.5 mg/kg PO twice daily; to reach steady state levels faster may give an IV loading dose of 20 mg/kg. Adjust dosage based upon therapeutic levels, efficacy, and adverse effects. (Podell 2000)
- b) Perform CBC, Biochem profile and urology study. Initial dose: 2 (1–2.5) mg/kg q12h. Increase the dosage 50–100% in puppies due to their increased metabolic rate; adjust dosages based upon serum levels. (Quesnel 2000)
- c) Initially, 2–4 mg/kg PO divided into 2–3 doses per day. If ineffective, may increase in a stepwise fashion to a maximum of 18–20 mg/kg/day (divided 2–3 times a day). Sudden discontinuation of the drug may result in seizures. (LeCouteur 1999)
- d) Loading dose of 16–20 mg/kg once IV; maintenance dose of 2–5 mg/kg PO q12h. (Knipe 2006a)
- e) Begin at 3.5 mg/kg PO twice daily. Monitor at 2 to 4 weeks and 3 months later to detect induction. If response is insufficient, increase dose sufficiently to increase trough level by 3 to 5 mcg/mL increments, rechecking at 2 to 4 weeks after each dose increase. Monitor at 3 to 12 month intervals once steady-state is achieved. As concentrations approach 30 mcg/mL, begin monitoring hepatic function test (bile acids, albumin, BUN, chol). As concentrations approach 35 mcg/mL, consider adding an additional drug. Avoid any other drug metabolized by the liver. Consider hepatoprotectant drugs if liver dysfunction is of concern. (Axlund 2004b)

For treatment of status epilepticus:

- a) If seizures persist after diazepam therapy (2 or more seizures recur; or gross motor activity persists) give phenobarbital bolus of 2–5 mg/kg (can be repeated at 20 minute intervals, up to two times). Add phenobarb to diazepam infusion at a rate

of 2–10 mg/hour. If seizures are sustained or high frequency seizures recur, consider pentobarbital coma. (Quesnel 2000)

For sedation:

- a) 2.2–6.6 mg/kg PO twice daily (Walton 1986)
- b) Treatment of irritable bowel syndrome: 2.2 mg/kg PO twice daily (Morgan 1988)
- c) For adjunctive treatment of compulsive behaviors: 2–20 mg/kg q12–24h (Line 2000)

■ **CATS:**

Treatment of idiopathic epilepsy:

- a) Perform CBC, Biochem profile and urology study. Initial dose: 2 (1–2.5) mg/kg q12h. Increase the dosage 50–100% possibly in kittens due to their increased metabolic rate; adjust dosages based upon serum levels. (Quesnel 2000)
- b) For status epilepticus: If seizures persist after diazepam therapy (2 or more seizures recur; or gross motor activity persists) give phenobarbital bolus of 2–5 mg/kg (can be repeated at 20 minute intervals, up to two times). Add phenobarb to diazepam infusion at a rate of 2–10 mg/hour. If seizures are sustained or high frequency seizures recur, consider pentobarbital coma.
For oral maintenance therapy: 1–2 mg/kg PO every 12 hours; adjust dosages based upon serum levels (Shell 2000)
- c) Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–5 mg/kg PO q12h. (Knipe 2006a)
- d) Starting dose is 1–2 mg/kg (usually 3.25–15 mg/cat) PO q12h. Measure trough serum levels 2–3 weeks after initiating therapy and after each dosage change. In the cat, therapeutic levels are likely 50–100 mcg/L (lower than those in dogs). If seizure control is good, but levels are subtherapeutic, dose does not need to be increased. Measure phenobarbital levels, CBC and serum chemistries every 6 months. (Cochrane 2007)

Sedation; for controlling excessive feline vocalization for situational distress (e.g., riding in automobiles):

- a) 2–3 mg/kg PO as needed (Overall 2000)

■ **FERRETS:**

- a) 1–2 mg/kg PO 2–3 times daily (Williams 2000)
- b) Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–2 mg/kg PO q8–12h. (Knipe 2006a)

■ **CATTLE:**

For enzyme induction in organochlorine toxicity:

- a) 5 grams PO for 3–4 weeks, off 3–4 weeks, then repeat for 3–4 more weeks (Smith 1986)

■ **HORSES: (Note: ARCI UCGFS Class 2 Drug)**

- a) Loading dose of 12 mg/kg IV over 20 minutes, then 6.65 mg/kg IV over 20 minutes every 12 hours (Duran et al. 1987)
- b) Adult horses: Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–5 mg/kg PO twice daily.
Foals: Loading dose of 16–20 mg/kg once IV; maintenance dose of 100–500 mg (total dose) PO twice daily. (Knipe 2006a)
- c) Foals for seizures: 20 mg/kg diluted with normal saline to a volume of 30–35 mL infused over 25–30 minutes IV, then 9 mg/kg diluted and infused as above q8h. Recommend monitoring serum levels if possible. (Spehar et al. 1984)

Monitoring

- Anticonvulsant (or sedative) efficacy
- Adverse effects (CNS related, PU/PD, weight gain)
- Serum phenobarbital levels if lack of efficacy or adverse reactions

noted. Some recommend that all dogs have their phenobarbital level monitored once a year and cats monitored every 6 months. Although there is some disagreement among clinicians, therapeutic serum levels in dogs (15–45 mcg/mL; 65–194 mcmol/L) are thought to be similar to those in humans. Therapeutic levels in cats may be closer to 12–30 mcg/mL (50–129 mcmol/L). Animals on bromides and phenobarbital may require lower serum levels for seizure control. If phenobarbital was not “loaded”, wait at least 5–6 half-lives (approximately 12–14 days in dogs and 9–10 days in cats) before measuring serum concentrations; time of sampling does not appear to be significant

- If used chronically, routine CBC's, liver enzymes (especially ALT and AST), and bilirubin at least every 6 months.

Client Information

- For successful epilepsy treatment compliance with prescribed therapy must be stressed. Encourage client to give doses at the same time each day.
- Keep medications out of reach of children and stored in child-resistant packaging.
- Veterinarian should be contacted if animal develops significant adverse reactions (including clinical signs of anemia and/or liver disease) or seizure control is unacceptable.

Chemistry/Synonyms

Phenobarbital, a barbiturate, occurs as white, glistening, odorless, small crystals or a white, crystalline powder with a melting point of 174°–178°C and a pK_a of 7.41. One gram is soluble in approximately 1000 mL of water; 10 mL of alcohol. Compared to other barbiturates it has a low-lipid solubility.

Phenobarbital sodium occurs as bitter-tasting, white, odorless, flaky crystals or crystalline granules or powder. It is very soluble in water, soluble in alcohol, and freely soluble in propylene glycol. The injectable product has a pH of 8.5–10.5.

SI units (mcmol/L) are multiplied by 0.232 to convert phenobarbital levels to conventional units (mcg/mL).

Phenobarbital may also be known as fenobarbital, phenemalum, phenobarbitalum, phenobarbitone, phenylethylbarbituric acid, or phenylethylmalonylurea, *Luminal Sodium*® and *Solfoton*®.

Storage/Stability/Compatibility

Phenobarbital tablets should be stored in tight, light-resistant containers at room temperature (15–30°C); protect from moisture. Phenobarbital elixir should be stored in tight containers at 20–20°C.

Phenobarbital sodium injection should be stored at room temperature (15–30°C).

Aqueous solutions of phenobarbital are not very stable. Propylene glycol is often used in injectable products to help stabilize the solution. Solutions of phenobarbital sodium should not be added to acidic solutions nor used if they contain a precipitate or are grossly discolored.

The following solutions and drugs have been reported to be physically **compatible** with phenobarbital sodium: Dextrose IV solutions, Ringer's injection, lactated Ringer's injection, Saline IV solutions, dextrose-saline combinations, dextrose-Ringer's combinations, dextrose-Ringer's lactate combinations, amikacin sulfate, aminophylline, atropine sulfate (stable for at least 15 minutes, but not 24 hours), calcium chloride and gluconate, cephalirin sodium, dimenhydrinate, polymyxin B sulfate, sodium bicarbonate, thio-pental sodium, and verapamil HCl.

The following drugs have been reported to be physically **incompatible** with phenobarbital sodium: benzquinamide HCl, cephalothin sodium, chlorpromazine HCl, codeine phosphate, ephedrine

sulfate, fentanyl citrate, glycopyrrolate, hydralazine HCl, hydrocortisone sodium succinate, hydroxyzine HCl, insulin (regular), meperidine HCl, morphine sulfate, nalbuphine HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, procaine HCl, prochlorperazine edisylate, promazine HCl, promethazine HCl, and streptomycin sulfate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Phenobarbital Tablets: 15 mg, 16 mg (tablets and capsules), 30 mg, 60 mg, 90 mg, & 100 mg; *Solfoton*® (ECR Pharm); generic; (Rx, C-IV)

Phenobarbital Elixir: 15 mg/5mL in pt and UD 5 mL, 10 mL and 20 mL; 20 mg/5mL in pt, gal, UD 5 mL and 7.5 mL; generic; (Rx, C-IV)

Phenobarbital Sodium Injection: 30 mg/mL, 60 mg/mL, 65 mg/mL, & 130 mg/mL in 1 mL *Tubex*, *Carpuijects* and vials; *Luminal Sodium*® (Hospira); generic; (Rx, C-IV)

PHENOXYBENZAMINE HCL

(fen-ox-ee-ben-za-meen) Dibenzyline®

ALPHA-ADRENERGIC BLOCKER

Prescriber Highlights

- ▶ Alpha-adrenergic blocker used in small animals: detrusor areflexia, pheochromocytoma (hypertension); horses: laminitis or diarrhea
- ▶ Contraindications: When hypotension would be deleterious; possibly glaucoma or diabetes mellitus, horses with clinical signs of colic. Caution: CHF or other heart disease, renal damage, or cerebral/coronary arteriosclerosis
- ▶ Adverse Effects: Hypotension, hypertension (rebound), miosis, increased intraocular pressure, tachycardia, inhibition of ejaculation, nasal congestion, weakness/dizziness, & GI effects (e.g., nausea, vomiting). Constipation may occur in horses.
- ▶ May need to be obtained from compounding pharmacy
- ▶ Drug Interactions

Uses/Indications

Phenoxybenzamine is used in small animals primarily for its effect in reducing internal urethral sphincter tone in dogs and cats when urethral sphincter hypertonus is present. It can also be used to treat the hypertension associated with pheochromocytoma prior to surgery or as adjunctive therapy in endotoxemia.

In horses, phenoxybenzamine has been used for preventing or treating laminitis in its early stages and to treat secretory diarrheas.

Pharmacology/Actions

Alpha-adrenergic response to circulating epinephrine or norepinephrine is noncompetitively blocked by phenoxybenzamine. The effect of phenoxybenzamine has been described as a "chemical sympathectomy." No effects on beta-adrenergic receptors or on the parasympathetic nervous system occur.

Phenoxybenzamine causes cutaneous blood flow to increase, but little effects are noted on skeletal or cerebral blood flow. Phenoxybenzamine can also block pupillary dilation, lid retraction, and nictitating membrane contraction. Both standing and supine blood pressures are decreased in humans.

Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, phenoxybenzamine is variably absorbed from the GI, with a bioavailability of 20–30%. Onset of action of the drug is slow (several hours) and increases over several days after regular dosing. Effects persist for 3–4 days after discontinuation of the drug.

Phenoxybenzamine is highly lipid soluble and may accumulate in body fat. It is unknown if it crosses the placenta or is excreted into milk. The serum half-life is approximately 24 hours in humans. It is metabolized (dealkylated) and excreted in both the urine and bile.

Contraindications/Precautions/Warnings

Phenoxybenzamine is contraindicated in horses with clinical signs of colic and in patients when hypotension would be undesirable (e.g., shock, unless fluid replacement is adequate). One author (Labato 1988) lists glaucoma and diabetes mellitus as contraindications for the use of phenoxybenzamine in dogs.

Phenoxybenzamine should be used with caution in patients with CHF or other heart disease as drug-induced tachycardia can occur. It should be used cautiously in patients with renal damage or cerebral/coronary arteriosclerosis.

Adverse Effects

Adverse effects associated with alpha-adrenergic blockade include: hypotension, hypertension, miosis, increased intraocular pressure, tachycardia, sodium retention, inhibition of ejaculation, and nasal congestion. Additionally, it can cause weakness/dizziness and GI effects (e.g., nausea, vomiting). Constipation may occur in horses.

Reproductive/Nursing Safety

Phenoxybenzamine has been shown to cause abnormalities in the closure of the patent ductus in guinea pigs. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if phenoxybenzamine is excreted into milk.

Overdosage/Acute Toxicity

Overdosage of phenoxybenzamine may yield signs of postural hypotension (dizziness, syncope), tachycardia, vomiting, lethargy, or shock.

Treatment should consist of emptying the gut if the ingestion was recent and there are no contraindications to those procedures. Hypotension can be treated with fluid support. Epinephrine is contraindicated (see Drug Interactions) and most vasopressor drugs are ineffective in reversing the effects of alpha-blockade. Intravenous norepinephrine (levarterenol) may be beneficial, however, if clinical signs are severe.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenoxybenzamine and may be of significance in veterinary patients:

- **EPINEPHRINE:** If used with drugs that have both alpha- and beta-adrenergic effects increased hypotension, vasodilatation or tachycardia may result
- **PHENYLEPHRINE:** Phenoxybenzamine will antagonize the effects of alpha-adrenergic sympathomimetic agents
- **RESERPINE:** Phenoxybenzamine can antagonize the hypothermic effects of reserpine

Doses

■ DOGS:

To treat functional urethral obstruction by decreasing sympathetic-mediated urethral tone:

- a) 0.25 mg/kg PO q12–24h or 2.5–20 mg (total dose) PO q12–24h (Lane 2000)
- b) 0.25 mg/kg PO q12h (Lulich 2004)
- c) 0.25–0.5 mg/kg PO once or twice daily (Coates 2004)
- d) 5–15 mg (total dose) PO q12h (Bartges 2003a)

Treatment of hypertension associated with pheochromocytoma:

- a) 0.2–1.5 mg/kg PO twice daily for 10–14 days before surgery; start at low end of dosage range and increase until blood pressure reduced to desired range. Propranolol (0.15–0.5 mg/kg PO three times a day) may be added to help control arrhythmias and hypertension. Beta-blockers must be used with phenoxybenzamine or severe hypertension may result. (Wheeler 1986)
- b) Initial dose is 0.25 mg/kg PO twice daily, followed by gradual increase every few days until dog shows improvement or signs of hypotension. Maximum dosage is around 1.5–2 mg/kg twice daily. (Reusch 2006)

For adjunctive treatment of endotoxemia with appropriate antimicrobial agents, steroids (if indicated), and other supportive care:

- a) 0.25–0.5 mg/kg PO q6h (Coppock and Mostrom 1986)

■ CATS:

To treat functional urethral obstruction by decreasing sympathetic-mediated urethral tone:

- a) 2.5–7.5 mg/cat PO once to twice daily (Osborne, Kruger et al. 2000)
- b) 1.25–7.5 mg (total dose) PO q12–24h (Lane 2000)
- c) 2.5–10 mg (total dose) PO q24h (Bartges 2003a)

For short-term treatment of hypertension:

- a) 0.5 mg/kg q12h (Sparkes 2003b)
- b) 2.5 mg (total dose) q12h increasing by 2.5 mg up to a maximum of 10 mg (total dose) q12h PO (Brovido 2002)
- c) 2.5–7.5 mg per cat q8–12h (Waddell 2005)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- a) To decrease urethral sphincter tone in horses with bladder paresis: 0.7 mg/kg PO 4 times a day (in combination with bethanechol at 0.25–0.75 mg/kg PO 2–4 times a day) (Schott II and Carr 2003)
- b) For adjunctive treatment of laminitis (developmental phase): 1 mg/kg IV q12h for 2 doses (Brumbaugh, Lopez et al. 1999)
- c) For treatment of profuse, watery diarrhea: 200–600 mg q12h (Clark 1988)

Monitoring

- Clinical efficacy (adequate urination, etc.)
- Blood pressure, if necessary/possible

Client Information

- Contact veterinarian if animal has continuing problems with weakness, appears dizzy, collapses after standing, or has persistent vomiting. GI upset may be reduced if the drug is given with meals.

Chemistry/Synonyms

An alpha-adrenergic blocking agent, phenoxybenzamine HCl occurs as an odorless, white crystalline powder with a melting range of 136°–141° and a pK_a of 4.4. Approximately 40 mg are soluble in 1 mL of water and 167 mg are soluble in 1 mL of alcohol.

Phenoxybenzamine may also be known as: SKF-688A, *Dibenyline*®, *Dibenzylan*®, or *Fenoxene*®.

Storage/Stability

Phenoxybenzamine capsules should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None; contact compounding pharmacies for dosage form availability.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Phenoxybenzamine HCl Capsules: 10 mg; *Dibenzylan*® (Wellspring); (Rx)

PHENYLBUTAZONE

(fen-ill-*byoo*-ta-zone) Butazolidin®, “Bute”

NON-STEROIDAL ANTIINFLAMMATORY AGENT**Prescriber Highlights**

- ▶ **NSAID used primarily in horses; little reason to use in dogs today**
- ▶ **Contraindications:** Known hypersensitivity, history or preexisting hematologic or bone marrow abnormalities, preexisting GI ulcers, food producing animals
- ▶ **Caution:** Foals or ponies, preexisting renal disease, CHF, other drug allergies
- ▶ **Adverse Effects:** **HORSES:** Oral & GI erosions & ulcers, hypoalbuminemia, diarrhea, anorexia, & renal effects. **DOGS:** GI ulceration, sodium & water retention, diminished renal blood flow, blood dyscrasias.
- ▶ **Do not give IM or SC; IA injections may cause seizures**
- ▶ **Drug Interactions;** lab interactions

Uses/Indications

One manufacturer lists the following as the indications for phenylbutazone: “For the relief of inflammatory conditions associated with the musculoskeletal system in dogs and horses.” (Package Insert; *Butazolidin*®—Coopers). It has been used primarily for the treatment of lameness in horses and, occasionally, as an analgesic/antiinflammatory, antipyretic in dogs, cattle, and swine.

Pharmacology/Actions

Phenylbutazone has analgesic, antiinflammatory, antipyretic, and mild uricosuric properties. The proposed mechanism of action is by the inhibition of cyclooxygenase, thereby reducing prostaglandin synthesis. Other pharmacologic actions phenylbutazone may induce include reduced renal blood flow and decreased glomerular filtration rate, decreased platelet aggregation, and gastric mucosal damage.

Pharmacokinetics

Following oral administration, phenylbutazone is absorbed from both the stomach and small intestine. The drug is distributed throughout the body with highest levels attained in the liver, heart, lungs, kidneys, and blood. Plasma protein binding in horses exceeds 99%. Both phenylbutazone and oxyphenbutazone cross the placenta and are excreted into milk.

The serum half-life in the horse ranges from 3.5–6 hours, and like aspirin is dose-dependent. Therapeutic efficacy, however, may last for more than 24 hours, probably due to the irreversible binding of phenylbutazone to cyclooxygenase. In horses and other species, phenylbutazone is nearly completely metabolized, primarily to oxyphenbutazone (active) and gamma-hydroxyphenylbutazone. Oxyphenbutazone has been detected in horse urine up to 48 hours after a single dose. Phenylbutazone is more rapidly excreted into alkaline than acidic urine.

Other serum half-lives reported for animals are: Cattle ≈ 40–55 hrs; Dogs ≈ 2.5–6 hrs; Swine ≈ 2–6 hrs.; Rabbits ≈ 3 hrs.

Contraindications/Precautions/Warnings

Phenylbutazone is contraindicated in patients with a history of or preexisting hematologic or bone marrow abnormalities, preexisting GI ulcers, and in food producing animals or lactating dairy cattle. Cautious use in both foals and ponies is recommended because of increased incidences of hypoproteinemia and GI ulceration. Foals with a heavy parasite burden or that are undernourished may be more susceptible to developing adverse effects.

Phenylbutazone may cause decreased renal blood flow and sodium and water retention, and should be used cautiously in animals with preexisting renal disease or CHF.

Because phenylbutazone may mask clinical signs of lameness in horses for several days following therapy, unethical individuals may use it to disguise lameness for “soundness” exams. States may have different standards regarding the use of phenylbutazone in track animals. Complete elimination of phenylbutazone in horses may take 2 months and it can be detected in the urine for at least 7 days following administration. Phenylbutazone is contraindicated in patients demonstrating previous hypersensitivity reactions to it, and should be used very cautiously in patients with a history of allergies to other drugs.

Do not administer injectable preparation IM or SC as it is very irritating (swelling, to necrosis and sloughing). Intracarotid injections may cause CNS stimulation and seizures.

Adverse Effects

While phenylbutazone is apparently a safer drug to use in horses and dogs than in people, serious adverse reactions can still occur. Toxic effects that have been reported in horses include oral and GI erosions and ulcers, hypoalbuminemia, diarrhea, anorexia, and renal effects (azotemia, renal papillary necrosis). Unlike humans, it does not appear that phenylbutazone causes much sodium and water retention in horses at usual doses, but edema has been reported. In dogs, however, phenylbutazone may cause sodium and water retention, and diminished renal blood flow. Phenylbutazone-induced blood dyscrasias and hepatotoxicity have also been reported in dogs.

The primary concerns with phenylbutazone therapy in humans include its bone marrow effects (agranulocytosis, aplastic anemia), renal and cardiovascular effects (fluid retention to acute renal failure), and GI effects (dyspepsia to perforated ulcers). Other serious concerns with phenylbutazone include hypersensitivity reactions, neurologic, dermatologic, and hepatic toxicities.

IM or SC injection can cause swelling, necrosis and sloughing. Intracarotid injections may cause CNS stimulation and seizures.

Therapy should be halted at first signs of any toxic reactions (e.g., anorexia, oral lesions, depression, reduced plasma proteins, increased serum creatinine or BUN, leukopenia, or anemias). The use of sucralfate or the H₂ blockers (cimetidine, ranitidine) have been suggested for use in treating the GI effects. Misoprostol, a prostaglandin E analog, may also be useful in reducing the gastrointestinal effects of phenylbutazone.

Reproductive/Nursing Safety

Although phenylbutazone has shown no direct teratogenic effects, rodent studies have demonstrated reduced litter sizes, increased neonatal mortality, and increased stillbirth rates. Phenylbutazone should, therefore, be used in pregnancy only when the potential benefits of therapy outweigh the risks associated with it.

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

The safety of phenylbutazone during nursing has not been determined; use with caution.

Overdosage/Acute Toxicity

Manifestations (human) of acute overdosage with phenylbutazone include a prompt respiratory or metabolic acidosis with compensatory hyperventilation, seizures, coma, and acute hypotensive crisis. In an acute overdose, clinical signs of renal failure (oliguric, with proteinuria and hematuria), liver injury (hepatomegaly and jaundice), bone marrow depression, and ulceration (and perforation) of the GI tract may develop. Other symptoms reported in humans include: nausea, vomiting, abdominal pain, diaphoresis, neurologic and psychiatric symptoms, edema, hypertension, respiratory depression, and cyanosis.

There were 47 exposures to phenylbutazone reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 45 were dogs with 7 showing clinical signs. The remaining 2 reported cases consisted of 1 equine and 1 cat neither of which showed clinical signs. Common findings in dogs recorded in decreasing frequency included tremors, vomiting, anorexia, death and diarrhea.

Standard overdose procedures should be followed (empty gut following oral ingestion, etc.). Supportive treatment should be instituted as necessary and intravenous diazepam used to help control seizures. Monitor fluid therapy carefully, as phenylbutazone may cause fluid retention.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylbutazone and may be of significance in veterinary patients:

- **FUROSEMIDE:** Phenylbutazone may antagonize the increased renal blood flow effects caused by furosemide
- **HEPATOTOXIC DRUGS:** Phenylbutazone administered concurrently with hepatotoxic drugs may increase the chances of hepatotoxicity developing

- **NSAIDS:** Concurrent use with other NSAIDs may increase the potential for adverse reactions, however, some clinicians routinely use phenylbutazone concomitantly with flunixin in horses. One study did not show synergistic actions with flunixin, but did however, when phenylbutazone and ketoprofen were “stacked”.

- **PENICILLAMINE:** May increase the risk of hematologic and/or renal adverse reactions

- **PENICILLIN G:** Phenylbutazone may increase plasma half-life of penicillin G

- **SULFONAMIDES:** Phenylbutazone could potentially displace sulfonamides from plasma proteins; increasing the risk for adverse effects

- **WARFARIN:** Phenylbutazone could potentially displace warfarin from plasma proteins; increasing the risk for bleeding

Laboratory Considerations

- Phenylbutazone and oxyphenbutazone may interfere with **thyroid function tests** by competing with thyroxine at protein binding sites or by inhibiting thyroid iodine uptake.

Doses

■ DOGS:

Note: With the release of safer and approved NSAIDs, it is this author's (Plumb) opinion that there is little reason to use this agent today in dogs.

- a) 14 mg/kg PO three times daily initially (maximum of 800 mg/day regardless of weight), titrate dose to lowest effective dose (Package Insert; *Butazolidin*®—Coopers)
- b) For analgesia: 1–5 mg/kg PO q8h (Taylor 2003a)

■ CATTLE:

Note: The Food and Drug Administration (FDA) has issued an order prohibiting the extralabel use of phenylbutazone animal and human drugs in female dairy cattle 20 months of age or older. In addition, many believe that phenylbutazone use in any food animal should be banned.

- a) 4 mg/kg IV or orally q24h (Koritz 1986)
- b) 4–8 mg/kg PO or 2–5 mg/kg IV (Howard 1986)
- c) 10–20 mg/kg PO, then 2.5–5 mg/kg q24h or 10 mg/kg every 48 hours PO (Jenkins 1987)

■ HORSES:

- a) 4.4–8.8 mg/kg q24hrs PO or 3–6 mg/kg q12h IV (Do not exceed 8.8 mg/kg/day (Jenkins 1987)
- b) 1–2 grams IV per 454 kg (1000 lb.) horse. Injection should be made slowly and with care. Limit IV administration to no more than 5 successive days of therapy. Follow with oral forms if necessary; or 2–4 grams PO per 454kg (1000 lb.) horse. Do not exceed 4 grams/day. Use high end of dosage range initially, then titrate to lowest effective dose. (Package Insert; *Butazolidin*®—Coopers)
- c) For adjunctive treatment of colic (to reduce endotoxic effects): 2.2 mg/kg twice daily (Moore 1999)
- d) For adjunctive treatment of laminitis: 4.4 mg/kg IV or PO twice daily (Brumbaugh, Lopez et al. 1999)

■ SWINE:

- a) 4 mg/kg IV or orally q24h (Koritz 1986)
- b) 4–8 mg/kg PO or 2–5 mg/kg IV (Howard 1986)

Monitoring

- Analgesic/antiinflammatory/antipyretic effect
- Regular complete blood counts with chronic therapy (especially in dogs). The manufacturer recommends weekly CBC's early in therapy, and biweekly with chronic therapy
- Urinalysis &/or renal function parameters (serum creatinine/BUN) with chronic therapy
- Plasma protein determinations, especially in ponies, foals, and debilitated animals.

Client Information

- Do not administer injectable preparation IM or SC.
- Approved for use in dogs and horses not intended for food.
- The Food and Drug Administration (FDA) has issued an order prohibiting the extralabel use of phenylbutazone animal and human drugs in female dairy cattle 20 months of age or older.
- While phenylbutazone is not approved for use in beef cattle, and its use is discouraged, it is used. A general guideline for meat withdrawal times are: one dose = 30 days, 2 doses = 35 days, and 3 doses = 40 days. Contact FARAD for more information.

Chemistry/Synonyms

A synthetic pyrazolone derivative related chemically to aminopyrine, phenylbutazone occurs as a white to off-white, odorless crystalline powder that has a pK_a of 4.5. It is very slightly soluble in water and 1 gram will dissolve in 28 mL of alcohol. It is tasteless at first, but has a slightly bitter after-taste.

Phenylbutazone may also be known as: butadiene, fenilbutazona, bute, or phenylbutazonum, and *Phenylbute*®.

Storage/Stability

Oral products should be stored in tight, child-resistant containers if possible. The injectable product should be stored in a cool place (46–56° F) or kept refrigerated.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Note: The Food and Drug Administration (FDA) has issued an order prohibiting the extralabel use of phenylbutazone animal and human drugs in female dairy cattle 20 months of age or older.

Phenylbutazone Tablets: 100 mg, & 200 mg; Many trade name and generic products available. Approved for use in dogs. (Rx)

Phenylbutazone Tablets: 1 gram; Many trade name and generic products available. Approved for use in horses. Not to be used in animals used for food. (Rx)

Phenylbutazone Oral Powder: 1 gram in 10 grams of powder to be mixed into feed. *Phenylbute*® Powder (Phoenix), (Rx). Labeled for use in horses.

Phenylbutazone Paste Oral Syringes: containing 6 grams or 12 grams/syringe; Many trade name and generic products available. Approved for use in horses not intended for food purposes. (Rx)

Phenylbutazone Injection: 200 mg/mL in 100 mL vials; Many trade name and generic products available. Approved for use in horses. Not to be used in horses intended for food. (Rx)

HUMAN APPROVED PRODUCTS: None

PHENYLEPHRINE HCL (SYSTEMIC)

(fen-ill-ef-rin) Neo-Synephrine®

ALPHA-ADRENERGIC AGONIST

Prescriber Highlights

- ▶ Alpha-adrenergic used parenterally to treat hypotension without overt cardiostimulation
- ▶ Contraindications: Severe hypertension, ventricular tachycardia, or hypersensitive to it. Extreme Caution: Geriatric patients, patients with hyperthyroidism, bradycardia, partial heart block, or other heart disease
- ▶ Not a replacement for adequate volume therapy in patients with shock
- ▶ Adverse Effects: Reflex bradycardia, CNS effects (excitement, restlessness, headache), & rarely, arrhythmias
- ▶ Blood pressure must be monitored
- ▶ Extravasation injuries with phenylephrine can be very serious

Uses/Indications

Phenylephrine has been used to treat hypotension and shock (after adequate volume replacement), but many clinicians prefer to use an agent that also has cardiostimulatory properties. Phenylephrine is recommended for use to treat hypotension secondary to drug overdoses or idiosyncratic hypotensive reactions to drugs such as phenothiazines, adrenergic blocking agents, and ganglionic blockers. Its use to treat hypotension resulting from barbiturate or other CNS depressant agents is controversial. Phenylephrine has been used to increase blood pressure to terminate attacks of paroxysmal supraventricular tachycardia, particularly when the patient is also hypotensive. Phenylephrine has been used to both treat hypotension and prolong the effects of spinal anesthesia.

Ophthalmic uses of phenylephrine include use for some diagnostic eye examinations, reducing posterior synechiae formation, and relieving pain associated with complicated uveitis. It has been applied intranasally in an attempt to reduce nasal congestion.

Pharmacology/Actions

Phenylephrine has predominantly post-synaptic alpha-adrenergic effects at therapeutic doses. At usual doses, it has negligible beta effects, but these can occur at high doses.

Phenylephrine's primary effects, when given intravenously, include peripheral vasoconstriction with resultant increases in diastolic and systolic blood pressures, small decreases in cardiac output, and an increase in circulation time. A reflex bradycardia (blocked by atropine) can occur. Most vascular beds are constricted (renal splanchnic, pulmonary, cutaneous), but coronary blood flow is increased. Its alpha effects can cause contraction of the pregnant uterus and constriction of uterine blood vessels.

Pharmacokinetics

After oral administration, phenylephrine is rapidly metabolized in the GI tract and cardiovascular effects are generally unattainable via this route of administration. Following IV administration, pressor effects begin almost immediately and will persist for up to 20 minutes. The onset of pressor action after IM administration is usually within 10–15 minutes, and will last for approximately one hour.

It is unknown if phenylephrine is excreted into milk. It is metabolized by the liver, and the effects of the drug are also terminated by uptake into tissues.

Contraindications/Precautions/Warnings

Phenylephrine is contraindicated in patients with severe hypertension, ventricular tachycardia or those who are hypersensitive to it. It should be used with extreme caution in geriatric patients, patients with hyperthyroidism, bradycardia, and partial heart block or with other heart disease. Phenylephrine is not a replacement for adequate volume therapy in patients with shock.

Adverse Effects

At usual doses, a reflex bradycardia, CNS effects (excitement, restlessness, headache) and, rarely, arrhythmias are seen. Blood pressure must be monitored to prevent hypertension.

Extravasation injuries with phenylephrine can be very serious (necrosis and sloughing of surrounding tissue). Patient's IV sites should be routinely monitored. Should extravasation occur, infiltrate the site (ischemic areas) with a solution of 5–10 mg phentolamine (*Regitine*®) in 10–15 mL of normal saline. A syringe with a fine needle should be used to infiltrate the site with many injections.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known if these agents are excreted in maternal milk; exercise caution when administering to a nursing patient.

Overdosage/Acute Toxicity

Overdosage of phenylephrine can cause hypertension, seizures, vomiting, paresthesias, ventricular extrasystoles, and cerebral hemorrhage.

There were 36 exposures to phenylephrine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases all 36 were dogs with 12 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, inappropriate urination, hypertension, cyanosis and hypersalivation.

Hypertension, if severe, can be treated by the administration of phentolamine (an alpha blocking agent). Should cardiac arrhythmias require treatment, use a beta-blocking drug such as propranolol.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylephrine (systemically) and may be of significance in veterinary patients:

- **ALPHA-ADRENERGIC BLOCKERS** (phentolamine, phenothiazines, phenoxymethamine): Higher dosages of phenylephrine may be required to attain a pressor effect if these agents have been used prior to therapy
- **ANESTHETICS, GENERAL (halogenated)**: Phenylephrine potentially may induce cardiac arrhythmias when used with halothane anesthesia
- **ATROPINE** (and other **anticholinergics**): Block the reflex bradycardia caused by phenylephrine
- **BETA-ADRENERGIC BLOCKERS**: The cardiostimulatory effects of phenylephrine can be blocked
- **DIGOXIN**: Use with phenylephrine may cause increased myocardium sensitization

- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly selegiline): Monoamine oxidase (MAO) inhibitors should not be used with phenylephrine because of a pronounced pressor effect
- **OXYTOCIN**: When used concurrently with oxytocic agents, pressor effects may be enhanced
- **SYMPATHOMIMETIC AGENTS (epinephrine)**: Tachycardia and serious arrhythmias are possible

Doses

■ DOGS:

- a) As a constant rate infusion: 1–3 mcg/kg/minute in either 0.9% sodium chloride or D5W (Dhupa and Shaffron 1995)
- b) As a constant rate infusion: 0.5–3 mcg/kg/minute. (Ko 2007)
- c) As a vasopressor in catastrophic stages of hypovolemic shock: 1–3 mcg/kg/min (Rudloff 2002)

■ CATS:

- a) As a constant rate infusion: 1–3 mcg/kg/minute in either 0.9% sodium chloride or D5W (Dhupa and Shaffron 1995)
- b) As a constant rate infusion: 0.5–3 mcg/kg/minute. (Ko 2007)
- c) As a vasopressor in catastrophic stages of hypovolemic shock: 1–3 mcg/kg/min (Rudloff 2002)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- a) 5 mg IV (Enos and Keiser 1985)

Monitoring

- Cardiac rate/rhythm
- Blood pressure, and blood gases if possible

Client Information

- Parenteral phenylephrine should only be used by professionals in a setting where adequate monitoring is possible

Chemistry/Synonyms

An alpha-adrenergic sympathomimetic amine, phenylephrine HCl occurs as bitter-tasting, odorless, white to nearly white crystals with a melting point of 145–146°C. It is freely soluble in water and alcohol. The pH of the commercially available injection is 3–6.5.

Phenylephrine may also be known as: fenilefrina, phenylephrinum, or m-synephrine, *AH-chew D*®, *Little Colds Decongestant for Infants & Children*®, *Lusonal*®, *Nasop*®, *Neo-Synephrine*®, *Sudogest PE*®, and *Sudafed PE*®.

Storage/Stability/Compatibility

The injectable product should be stored protected from light. Do not use solutions if they are brown or contain a precipitate. Oxidation of the drug can occur without a color change. To protect against oxidation, the air in commercially available ampules for injection is replaced with nitrogen and a sulfite added.

Phenylephrine is reported to be physically **compatible** with all commonly used IV solutions and the following drugs: chloramphenicol sodium succinate, dobutamine HCl, lidocaine HCl, potassium chloride, and sodium bicarbonate. While stated to be physically **incompatible** with alkalis, it is stable with sodium bicarbonate solutions. Phenylephrine is reported to be **incompatible** with ferric salts, oxidizing agents, and metals.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

There are oral combination products marketed as “cough” syrups for veterinary use that contain phenylephrine, pyrilamine (antihistamine), guaifenesin, sodium citrate, and sometimes ammonium chloride.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Phenylephrine HCl Tablets: 10 mg (regular, chewable & orally disintegrating); *AH-chew D*® (WE Pharm); *Sudafed PE*® (Pfizer); *Sudogest PE*® (Major); *Nasop*® (Hawthorn); (OTC or Rx)

Phenylephrine HCl Oral Suspension/Liquid/Drops: 2.5 mg/mL, 7.5 mg/5 mL & 2 mg (as phenylephrine HCl)/mL; in 15 mL, 20 mL, 30 mL or 118 mL; *AH-chew D*® (WE Pharm); *Little Colds Decongestant for Infants & Children*® (Vetco); *Lusonal*® (WraSer); (OTC or Rx)

Phenylephrine HCl Strips: 10 mg; *Sudafed PE Quick-dissolve* (Pfizer Consumer Healthcare); (OTC)

Phenylephrine HCl Injection: 1% (10 mg/mL) in 1 mL and 5 mL vials and 1 mL Uni-Nest amps; *Neo-Synephrine*® (Sanofi Winthrop); generic; (Rx)

Phenylephrine is also available in ophthalmic and intranasal dosage forms and in combination with antihistamines, analgesics, decongestants, etc., for oral administration in humans.

PHENYLPROPANOLAMINE HCL

(fen-ill-proe-pa-nole-a-meen) PPA

SYMPATHOMIMETIC**Prescriber Highlights**

- ▶ Sympathomimetic used primarily for urethral sphincter hypotonus
- ▶ Caution: Glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension
- ▶ Adverse Effects: Restlessness, irritability, hypertension, & anorexia

Uses/Indications

Phenylpropanolamine is used chiefly for the treatment of urethral sphincter hypotonus and resulting incontinence in dogs and cats. It has also been used in an attempt to treat nasal congestion in small animals.

Pharmacology/Actions

While the exact mechanisms of phenylpropanolamine's actions are undetermined, it is believed that it indirectly stimulates both alpha- and beta-adrenergic receptors by causing the release of norepinephrine. Prolonged use or excessive dosing frequency can deplete norepinephrine from its storage sites, and tachyphylaxis (decreased response) may ensue. Tachyphylaxis has not been documented in dogs or cats when used for urethral sphincter hypotonus, however.

Pharmacologic effects of phenylpropanolamine include increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased nasal congestion and appetite. Phenylpropanolamine can also increase urethral sphincter tone and produce closure of the bladder neck; its principal veterinary indications are because of these effects.

Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, phenylpropanolamine is readily absorbed after oral administration and has an onset of action (nasal decongestion) of about 15–30 minutes with duration of effect lasting approximately 3 hours (regular capsules or tablets).

Phenylpropanolamine is reportedly distributed into various tissues and fluids, including the CNS. It is unknown if it crosses the placenta or enters milk. The drug is partially metabolized to an active metabolite, but 80–90% is excreted unchanged in the urine within 24 hours of dosing. The serum half-life is approximately 3–4 hours.

Contraindications/Precautions/Warnings

Phenylpropanolamine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension.

Adverse Effects

Most likely side effects include restlessness, irritability, urine retention, tachycardia, and hypertension. Anorexia may be a problem in some animals. Rare reports of “stroke” have occurred in dogs given therapeutic dosages of phenylpropanolamine.

Reproductive/Nursing Safety

Phenylpropanolamine may cause decreased ovum implantation; uncontrolled clinical experience, however, has not demonstrated any untoward effects during pregnancy.

Overdosage/Acute Toxicity

Clinical signs of overdosage may consist of an exacerbation of the adverse effects listed above or, if a very large over-dose, severe cardiovascular (hypertension to rebound hypotension, bradycardias to tachycardias, and cardiovascular collapse) or CNS effects (stimulation to coma) can be seen.

There were 255 exposures to phenylpropanolamine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 250 were dogs with 59 showing clinical signs. The remaining 5 cases were cats that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included hypertension, piloerection, vomiting, bradycardia and mydriasis.

A dog ingesting 48 mg/kg of PPA has been reported (Crandell and Ware 2005). Ventricular tachycardia and regions of myocardial necrosis were noted. All abnormalities resolved within 6 months.

If the overdose was recent, empty the stomach using the usual precautions and administer charcoal and a cathartic. Treat clinical signs supportively as they occur. Do not use propranolol to treat hypertension in bradycardic patients and do not use atropine to treat bradycardia. Hypertension may be managed with a phenothiazine (e.g., acepromazine—very low dose such as 0.02 mg/kg IV or IM). If phenothiazines do not normalize blood pressure, consider using a CRI of nitroprusside. Contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylpropanolamine and may be of significance in veterinary patients:

- **HALOTHANE:** An increased risk of arrhythmias developing can occur if phenylpropanolamine is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly **selegiline**): Phenylpropanolamine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors
- **NSAIDS:** An increased chance of hypertension if given concomitantly with NSAIDs, including aspirin
- **RESERPINE:** An increased chance of hypertension if given concomitantly
- **SYMPATHOMIMETIC AGENTS, OTHER:** Phenylpropanolamine should not be administered with other sympathomimetic agents (e.g., ephedrine) as increased toxicity may result
- **TRICYCLIC ANTIDEPRESSANTS** (**clomipramine**, **amitriptyline**, etc.): An increased chance of hypertension if given concomitantly

Doses

■ DOGS:

For urethral sphincter hypotonus:

- a) 12.5–50 mg PO q8h (Labato 1988), (Polzin and Osborne 1985), (Bartges 2003a)
- b) Using the time-release 75 mg capsules: Dogs weighing less than 40 lbs: 1/2 capsule PO daily. Dogs 40–100 lbs: 1 capsule PO daily. Dogs weighing >100 lbs: 1.5 capsules PO per day. (Label information; *Cystolamine*® —VPL)
- c) 1–1.5 mg/kg PO two to three times a day controls 74–92% of dogs with primary sphincter mechanism incontinence. Over half of dogs not responding to regular PPA will respond to sustained-release PPA. Incontinence control becomes less over time in some dogs. (Chew 2007)
- d) 5–50 mg per dog PO q8h or 1.5 mg/kg PO q8h–12h (Ver-nau 2006)

For retrograde ejaculation:

- a) 3–4 mg/kg PO twice daily may be tried. (Fontbonne 2007)

■ CATS:

For urethral sphincter hypotonus:

- a) 12.5 mg PO q8h (Labato 1988), (Polzin and Osborne 1985)
- b) 1.5 mg/kg PO q8h (Bartges 2003a)
- c) 1.1–2.2 mg/kg PO two to three times daily (Lane 2003)

Monitoring

- Clinical effectiveness
- Adverse effects (see above)
- Blood pressure

Client Information

- In order for this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.
- Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

Chemistry/Synonyms

A sympathomimetic amine, phenylpropanolamine HCl occurs as a white crystalline powder with a slightly aromatic odor, a melting range between 191°–194°C, and a pK_a of 9.4. One gram is soluble in approximately 1.1 mL of water or 7 mL of alcohol.

Phenylpropanolamine may also be known as: (+/-)-norephedrine, dl-norephedrine or PPA, *Cystolamine*®, *Proin*®, *Propalin*®, *Uricon*®, and *Uriflex-PT*®.

Storage/Stability/Compatibility

Store phenylpropanolamine products at room temperature in light-resistant, tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Phenylpropanolamine Chewable Tablets: 25 mg, 50 mg, & 75 mg; *Proin*® (PRN Pharmacal), *Propalin*® (Vetoquinol), *Uriflex-PT*® (Butler), *Uricon*® (Neogen); (Rx). Labeled for use in dogs.

Phenylpropanolamine Timed-Release Capsules: 75 mg; *Cystolamine*® (VPL); (Rx). Labeled for use in dogs.

Phenylpropanolamine oral solution: 25 mg/mL in 60 mL bottles; *Proin*® Drops (PRN Pharmacal) (Rx); 50 mg/mL in 30 mL and 100 mL bottles; (Rx). Labeled for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

In the USA, phenylpropanolamine is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

HUMAN-LABELED PRODUCTS:

Note: Because of potential adverse effects in humans, phenylpropanolamine has been removed from the US market for human use.

PHENYTOIN SODIUM

(*fen-i-toe-in*) Dilantin®

ANTICONVULSANT, ANTIDYSRHYTHMIC

Prescriber Highlights

- Rarely used (in USA) for seizures in small animals; sustained release formulations may be useful (not available in USA)
- Potentially useful as a treatment for ventricular dysrhythmias in horses or digoxin-induced arrhythmias in dogs or horses; may be useful in cats with myokemia and neuro-myotonia
- Contraindications: Hypersensitivity; IV use contraindicated for 2nd or 3rd degree heart block, sinoatrial block, Adams-Stokes syndrome, or sinus bradycardia.
- Adverse Effects: DOGS: Anorexia & vomiting, ataxia, sedation, gingival hyperplasia, hepatotoxicity. CATS: Ataxia, sedation, anorexia, dermal atrophy syndrome, thrombocytopenia
- Potentially teratogenic; many drug interactions possible

Uses/Indications

Because of its undesirable pharmacokinetic profiles in dogs and cats, the use of phenytoin as an anticonvulsant for long-term treatment of epilepsy has diminished over the years and few use it today for this purpose. It remains, however, of interest due to its efficacy in humans, and the potential for sustained-release products to be marketed for dogs. Until then prerequisites for successful therapy in dogs include: a motivated client who will be compliant with multiple daily dosing and willing to assume the financial burden of high dose phenytoin therapy and therapeutic drug monitoring expenses.

Although not commonly used, phenytoin has been employed as an oral or IV antiarrhythmic agent in both dogs and cats. It has been described as the drug of choice for digitalis-induced ventricular arrhythmias in dogs. A cat with myokemia and neuromyotonia was treated with phenytoin in a recent case report (Galano, Olby et al. 2005).

Phenytoin has been studied as a treatment for ventricular dysrhythmias in horses and preliminary reports demonstrate efficacy (Wijnberg and Ververs 2004).

It has been suggested that phenytoin be used as adjunctive treatment of hypoglycemia secondary to hyperinsulinism, but apparently, little clinical benefit has resulted from this therapy.

Pharmacology/Actions

The anticonvulsant actions of phenytoin are thought to be caused by the promotion of sodium efflux from neurons, thereby inhibiting the spread of seizure activity in the motor cortex. It is believed that excessive stimulation or environmental changes can alter the sodium gradient, which may lower the threshold for seizure spread. Hydantoines tend to stabilize this threshold and limit seizure propagation from epileptogenic foci.

The cardiac electrophysiologic effects of phenytoin are similar (not identical) to that of lidocaine (Group 1B). It depresses phase 0 slightly and can shorten the action potential. Its principle cardiac use is in the treatment of digitalis-induced ventricular arrhythmias.

Phenytoin can inhibit insulin and vasopressin (ADH) secretion.

Pharmacokinetics

After oral administration, phenytoin is nearly completely absorbed in humans, but in dogs, bioavailabilities may only be about 40%. Phenytoin is well distributed throughout the body and about 78% bound to plasma proteins in dogs (vs. 95% in humans). Protein binding may be reduced in uremic patients. Small amounts of phenytoin may be excreted into the milk and it readily crosses the placenta.

The drug is metabolized in the liver with much of the drug conjugated to a glucuronide form and then excreted by the kidneys. Phenytoin will induce hepatic microsomal enzymes, which may enhance the metabolism of itself and other drugs. The serum half-life (elimination) differences between various species are striking. Phenytoin has reported half-lives of 2–8 hours in dogs, 8 hours in horses, 15–24 hours in humans, and 42–108 hours in cats. Because of the pronounced induction of hepatic enzymes in dogs, phenytoin metabolism is increased with shorter half-lives within 7–9 days after starting treatment. Puppies possess smaller volumes of distribution and shorter elimination half-lives (1.6 hours) than adult dogs.

Contraindications/Precautions/Warnings

Some data suggest that additive hepatotoxicity may result if phenytoin is used with either primidone or phenobarbital. Weigh the potential risks versus the benefits before adding phenytoin to either of these drugs in dogs.

Phenytoin is contraindicated in patients known to be hypersensitive to it or other hydantoines. Intravenous use of the drug is contraindicated in patients with 2nd or 3rd degree heart block, sinoatrial block, Adams-Stokes syndrome, or sinus bradycardia.

Adverse Effects

Adverse effects in dogs associated with high serum levels include anorexia and vomiting, ataxia, and sedation. Liver function tests should be monitored in patients on chronic therapy as hepatotoxicity (elevated serum ALT, decreased serum albumin, hepatocellular hypertrophy and necrosis, hepatic lipidosis, and extramedullary hematopoiesis) have been reported. Gingival hyperplasia has been reported in dogs receiving chronic therapy. Oral absorption may be enhanced and GI upset decreased if given with food.

Cats exhibit ataxia, sedation, and anorexia secondary to accumulation of phenytoin and high serum levels. Cats have also been reported to develop thrombocytopenia and a dermal atrophy syndrome secondary to phenytoin.

High plasma concentrations of phenytoin in horses can cause excitement and recumbency.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Phenytoin is excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, consider whether to accept the risks, discontinue nursing or to discontinue the drug.

Overdosage/Acute Toxicity

Clinical signs of overdosage may include sedation, anorexia, and ataxia at lower levels, and coma, hypotension, and respiratory depression at higher levels. Treatment of overdoses in dogs is dependent on the severity of the clinical signs demonstrated, since dogs rapidly clear the drug. Severe intoxications should be handled supportively.

Drug Interactions

■ **CHLORAMPHENICOL:** A case report of chloramphenicol increasing the serum half-life of phenytoin from 3 to 15 hours in a dog has been reported.

Note: The following interactions are from the human literature: because of the significant differences in pharmacokinetics in dogs and cats, their veterinary significance will be variable. This list includes only agents used in small animal medicine, many more agents have been implicated in the human literature:

■ **LITHIUM:** The toxicity of lithium may be enhanced.

■ **MEPERIDINE:** Phenytoin may decrease the analgesic properties meperidine, but enhance its toxic effects.

■ **PHENOBARBITAL/PRIMIDONE:** The pharmacologic effects of primidone may be altered. Some data suggest that additive hepatotoxicity may result if phenytoin is used with either primidone or phenobarbital. Weigh the potential risks versus the benefits before adding phenytoin to either of these drugs in dogs.

The following agents may **increase the effects of phenytoin:**

■ **ALLOPURINOL**

■ **CHLORAMPHENICOL**

■ **CHLORPHENIRAMINE**

- CIMETIDINE
- DIAZEPAM
- ETHANOL
- ISONIAZID
- PHENYLBUTAZONE
- SALICYLATES
- SULFONAMIDES
- TRIMETHOPRIM
- VALPROIC ACID

The following agents may **decrease the pharmacologic activity of phenytoin**:

- ANTACIDS
- ANTINEOPLASTICS
- BARBITURATES
- CALCIUM (DIETARY AND GLUCONATE)
- DIAZOXIDE
- ENTERAL FEEDINGS
- FOLIC ACID
- NITROFURANTOIN
- PYRIDOXINE
- THEOPHYLLINE

Phenytoin may **decrease the pharmacologic activity of the following agents**:

- CORTICOSTEROIDS
- DISOPYRAMIDE
- DOPAMINE
- DOXYCYCLINE
- ESTROGENS
- FUROSEMIDE
- QUINIDINE

Doses

■ DOGS:

For treatment of seizures:

- a) 15–40 mg/kg PO three times daily (Morgan 1988)
- b) 20–35 mg/kg three times daily (Bunch 1986)
- c) Initially, 8.8–17.6 mg/kg PO in divided doses, then gradually increase or decrease dose to maintain control. May take several days for seizure control to be attained. (Package insert; *Dilantin® Veterinary*—Parke-Davis)

(Plumb's Note): Because of the extremely fast half-life of phenytoin in dogs, it is unlikely that this dosage regimen ("c") will attain serum levels of 10–20 micrograms/mL which are thought to be necessary for adequate seizure control.

For treatment of ventricular arrhythmias:

- a) Up to 10 mg/kg IV in increments of 2–4 mg/kg or 20–35 mg/kg PO three times daily (Moses 1988)
- b) 10 mg/kg slowly IV; 30–50 mg/kg PO q8h (Ware 2003)

For treatment (or prophylaxis) of digitalis intoxication:

- a) 50 mg/kg PO q8h; long-term use may cause increases in serum alkaline phosphatase and increased hepatic cell size. (Kittleson 2006c)

For treatment of hypoglycemia secondary to tumor:

- a) 6 mg/kg PO two to three times daily (Morgan 1988)

■ CATS:

Note: Because cats can easily accumulate this drug and develop clinical signs of toxicity, the use of phenytoin is very controversial in this species. Diligent monitoring is required.

- a) For treatment of ventricular arrhythmias: 2–3 mg/kg PO q24h (Wilcke 1985)
- b) For treatment of seizures: 2–3 mg/kg daily PO; 20 mg/kg per week (Bunch 1986)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) For seizures: 2.83–16.43 mg/kg PO q8h to obtain serum levels from 5–10 micrograms/mL. Suggest monitoring serum levels to adjust dosage. (Kowalczyk and Beech 1983)
- b) For digoxin induced arrhythmias: 10–22 mg/kg PO q12h. Adverse effects are muscle fasciculations and sedation. (Mogg 1999)
- c) For treatment of ventricular dysrhythmias: For persistent ventricular extra systoles or ventricular tachycardia where conventional treatment has failed: 20 mg/kg PO q12h initially for the first 3–4 doses, followed by a maintenance dose of 10–15 mg/kg PO q12h. Suggest monitoring plasma concentrations. (Wijnberg and Ververs 2004)

Monitoring

- Level of seizure control; sedation/ataxia
- Body weight (anorexia)
- Liver enzymes (if chronic therapy) and serum albumin
- Serum drug levels if signs of toxicity or lack of seizure control

Client Information

- Notify veterinarian if patient becomes anorexic, lethargic, ataxic, or seizures are not adequately controlled.
- The importance of regular dosing is imperative for successful therapy.

Chemistry/Synonyms

A hydantoin-derivative, phenytoin sodium occurs as a white, hygroscopic powder which is freely soluble in water and warm propylene glycol, and soluble in alcohol.

Because phenytoin sodium slowly undergoes partial hydrolysis in aqueous solutions to phenytoin (base) with the resultant solution becoming turbid, the commercial injection contains 40% propylene glycol and 10% alcohol. The pH of the injectable solution is approximately 12.

Phenytoin sodium is used in the commercially available capsules (both extended and prompt) and the injectable preparations. Phenytoin (base) is used in the oral tablets and suspensions. Each 100 mg of phenytoin sodium contains 92 mg of the base.

Phenytoin may also be known as: diphenylhydantoin, DPH, fenitoina, phenantoinum, or phenytoinum, *Dilantin®*, and *Phenytek®*.

Storage/Stability/Compatibility

Store capsules at room temperature (below 86°F) and protect from light and moisture. Store phenytoin sodium injection at room temperature and protect from freezing. If injection is frozen or refrigerated, a precipitate may form which should resolubilize when warmed. A slight yellowish color will not affect either potency or efficacy, but do not use precipitated solutions. Injectable solutions at less than a pH of 11.5 will precipitate. No problems with adsorption to plastic have been detected thus far.

Phenytoin sodium injection is generally physically **incompatible** with most IV solutions (upon standing) and drugs. It has been successfully mixed with sodium bicarbonate and verapamil HCl.

Because an infusion of phenytoin sodium is sometimes desirable, several studies have been performed to determine whether such a procedure can be safely done. The general conclusions and recommendations of these studies are: **1)** use either normal saline or lactated Ringer's; **2)** a concentration of 1 mg/mL phenytoin be used; **3)** start infusion immediately and complete in a relatively short time; **4)** use a 0.22 µm in-line IV filter; **5)** watch the admixture carefully.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Phenytoin Sodium Extended-Release Capsules: 30 mg, 100 mg, 200 mg and 300 mg; *Dilantin Kapseals*® (Parke-Davis); *Phenytek*® (Bertek); generic, (Rx)

Phenytoin Oral Suspension: 25 mg/mL in 240 mL; *Dilantin-125*® (Parke-Davis); generic (Alpharma); (Rx)

Phenytoin Sodium, Prompt Capsules: 100 mg (92 mg phenytoin); generic; (Rx)

Phenytoin Tablets: 50 mg (chewable); *Dilantin*® *Infra-Tabs* (Parke-Davis); (Rx)

Phenytoin Sodium Injection: 50 mg/mL (46 mg/mL phenytoin) in 2 mL and 5 mL amps, 2 mL *Dosettes* & vials; generic (Elkins-Sinn); (Rx)

PHEROMONES

(*fer*-i-mones) Feliway®, D.A.P.®

PHEROMONE BEHAVIOR MODIFIER

Prescriber Highlights

- ▶ Commercially available pheromones may be useful in CATS for urine marking or spraying, vertical scratching, avoidance of social contact, loss of appetite, stressful situations, or inter-cat aggression; DOGS: Behaviors associated with fear or stress or for calming in new environments or situations; HORSES: Alleviating stressful situations
- ▶ May need adjunctive therapy (behavior modification, drug therapy) for negative behaviors
- ▶ Dog/Cat products are administered via the environment; Equine product administered intranasally
- ▶ Appears to be safe

Uses/Indications

In cats, FFP may be useful in treating urine marking or spraying, vertical scratching, avoidance of social contact, loss of appetite, stressful situations, or inter-cat aggression. Behavioral modification and/or concomitant drug therapy may be required.

In dogs, DAP may be useful in treating behaviors associated with fear or stress (e.g., separation anxiety, destruction, excessive barking, house soiling, licking, phobias) or calming animals in new environments or situations.

In horses, EAP may be useful in alleviating stressful situations (e.g., transport, shoeing, clipping, new environments, training).

Pharmacology/Actions

Appeasing pheromones produced during nursing are thought to exist with all mammals. They are detected by the Jacobson's organ or vomero-nasal organ (VNO). The VNO is more sensitive in young animals, but is believed to continue to function in older animals as well. It is not well understood what neurotransmitters or neurochemical processes are involved for pheromones to exhibit their effects. In most animals, pheromones have a general calming effect. In cats, the F3 facial pheromone is thought to inhibit urine marking, encourage feeding, and enhance exploratory behaviors in unfamiliar situations. The F4 pheromone is a so-called allomarking pheromone that calms and familiarizes the cat with its surroundings.

Pharmacokinetics

No information located.

Contraindications/Precautions/Reproductive Safety

No information located.

Adverse Effects

No significant adverse effects were located for these products and are unlikely to occur.

Overdosage/Acute Toxicity

No specific animal toxicity data was located. Although the ingredients in these products are not thought toxic, the manufacturer recommends that humans accidentally exposed resulting in an adverse reaction should report to a physician or poison control center.

Drug Interactions

None were located. Effects may be reduced or negated by concurrent use of drugs that cause CNS stimulation.

Laboratory Considerations

No information was located.

Doses

■ CATS:

- a) Diffusers: Diffuser vial lasts approximately 4 weeks and covers 500–650 sq. ft. Plug diffuser into electric outlet in the room most often used by the animal. Do not cover diffuser or place behind or under furniture. When plugged in, do not touch diffuser with wet hands or metal objects. Do not touch diffuser with uncovered hands during, or immediately after use. May require up to 72 hours to saturate area, so effects may not be immediate. (Label Information; *Feliway*® *Diffuser*—VPL)
- b) Spray: Do not spray directly on cats. Pump spray approximately 4 inches from site, 8 inches from the floor. One spray per application site. Clean urine marks with clear water only. Urine marks and prominent objects (furniture, window or doorframes) should be sprayed 1–2 times daily for 30 days. If cat is observed rubbing its own facial pheromones onto a spot, treatment is no longer necessary at that location. Maintenance sprays every 2–3 days may be required. Intercat aggression problems may require behavior modification and concomitant drug therapy. (Label Information; *Feliway*® *Spray*—VPL)

■ DOGS:

- a) Diffusers: Diffuser vial lasts approximately 4 weeks and covers 500–650 sq. ft. Plug diffuser into electric outlet in the room most often used by the animal. Do not cover diffuser or place behind or under furniture. When plugged in, do not touch diffuser with wet hands or metal objects. Do not touch diffuser with uncovered hands during, or immediately after

use. May require up to 72 hours to saturate area, so effects may not be immediate. (Label Information; *Feliway® Diffuser*—VPL)

- b) Spray: Do not spray directly on dogs. May spray in car, kennels, crates, carriers, or on neck bandanas. Spray approximately 20 minutes prior to travel, etc. When entering unfamiliar places/rooms, spray twice day in the area. (Label Information; *D.A.P.® Spray*—VPL)

■ HORSES:

- a) Administer 2 sprays into each nostril 1/2 hour before anticipated stress or event. After administration, keep horse in a non-stressful environment for 1/2 hour to achieve best results. (Label Information; *Modipher EQ® Spray*—VPL)

Monitoring

- Clinical efficacy

Chemistry

Mammalian pheromones are fatty acids. Dog appeasing pheromone (DAP) is a synthetic derivative of bitch intermammary pheromone. Feline pheromone is a synthetic analog of feline cheek gland secretions (feline facial pheromone; FFP). The commercially available product available in the USA is an analog of the F3 fraction of the pheromone. Equine appeasing pheromone (EAP) is derived from maternal pheromones found in the “wax area” close to the mammae of nursing mares.

Storage/Stability/Compatibility

Unless otherwise labeled, store at room temperature and do not mix with other ingredients or substances. Keep products out of reach of children.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Feline Facial Pheromone (FFP-F3 fraction) Diffuser (electric diffuser plus a 2% FFP vial) 48 mL vial; *Feliway® Diffuser* (Farnam); *Comfort Zone® Feline* (Farnam); (OTC)

Feline Facial Pheromone (FFP-F3 fraction) Spray 10% 75 mL bottle; *Feliway® Spray* (VPL); *Comfort Zone® Spray for Cats* (Farnam); (OTC)

Dog Appeasing Pheromone (DAP) Diffuser (electric diffuser plus a 2% DAP vial) 48 mL vial; *D.A.P.® Diffuser* (VPL); (OTC)

Dog Appeasing Pheromone 2% (DAP) Spray 60 mL bottle; *D.A.P.® Spray* (VPL); *Comfort Zone® Spray for Dogs* (Farnam); (OTC)

Dog Appeasing Pheromone (DAP) 48 mL with or without plug in adapter; *Comfort Zone® Canine* (Farnam); (OTC)

Dog Appeasing Pheromone Collar; *D.A.P.® Collar* (VPL), (OTC)

Equine Appeasing Pheromone (EAP) 0.1% Spray 7.5 mL bottle, *Modipher EQ® Mist with E.A.P.* (VPL); (OTC)

A product (not currently available in the USA) called *FeliFriend®* contains a synthetic F4 fraction of FFP.

HUMAN-LABELED PRODUCTS: None

PHOSPHATE, PARENTERAL POTASSIUM PHOSPHATE SODIUM PHOSPHATE

ELECTROLYTE

Prescriber Highlights

- For treatment or prevention of hypophosphatemia
- Contraindications: Hyperphosphatemia, hypocalcemia, oliguric renal failure, or if tissue necrosis is present; Potassium phosphate contraindicated if hyperkalemia present; sodium phosphate if hypernatremia present
- Caution: Cardiac (esp. if receiving digoxin) or renal disease
- Adverse Effects: Hyperphosphatemia, resulting in hypocalcemia, hypotension, renal failure or soft tissue mineralization; hyperkalemia or hypernatremia are possible
- Dilute before giving IV

Uses/Indications

Phosphate is useful in large volume parenteral fluids to correct or prevent hypophosphatemia when adequate oral phosphorous intake is not possible. Hypophosphatemia may cause hemolytic anemia, thrombocytopenia, neuromuscular and CNS disorders, bone and joint pain, and decompensation in patients with cirrhotic liver disease. There is some controversy whether “a low phos” indicates that treatment is necessary.

Pharmacology/Actions

Phosphate is involved in several functions in the body, including calcium metabolism, acid-base buffering, B-vitamin utilization, bone deposition, and several enzyme systems.

Pharmacokinetics

Intravenously administered phosphate is eliminated via the kidneys. It is glomerularly filtered, but up to 80% is reabsorbed by the tubules.

Contraindications/Precautions/Warnings

Both potassium and sodium phosphate are contraindicated in patients with hyperphosphatemia, hypocalcemia, oliguric renal failure, or if tissue necrosis is present. Potassium phosphate is contraindicated in patients with hyperkalemia. It should be used with caution in patients with cardiac or renal disease. Particular caution should be used in using this drug in patients receiving digitalis therapy.

Sodium phosphate is also contraindicated in patients with hypernatremia.

Adverse Effects

Overuse of parenteral phosphate can result in hyperphosphatemia, resulting in hypocalcemia (refer to the Overdose section for more information). Phosphate therapy can also result in hypotension, renal failure or soft tissue mineralization. Either hyperkalemia or hypernatremia may result in susceptible patients.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in maternal milk. It is unlikely to be of concern.

Overdosage/Acute Toxicity

Patients developing hyperphosphatemia secondary to intravenous therapy with potassium phosphate should have the infusion stopped and be given appropriate parenteral calcium therapy to restore serum calcium levels. Serum potassium should be monitored and treated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phosphates and may be of significance in veterinary patients:

- **ALUMINUM and CALCIUM SALTS (oral) and SEVELAMER:** May reduce phosphorus levels
- **ANGIOTENSIN CONVERTING ENZYME INHIBITORS (ACE Inhibitors):** May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.
- **DIGOXIN:** Potassium salts (potassium phosphate) must be used very cautiously in patients on digitalis therapy and should not be used in digitalized patients with heart block
- **POTASSIUM SPARING DIURETICS (e.g., spironolactone):** May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.

Doses

Both sodium and potassium phosphate injections must be diluted before intravenous administration.

■ DOGS & CATS:

For hypophosphatemia:

- a) For significant hypophosphatemia (<1.5 mg/dl) in patients unable to receive oral supplementation: 0.06 – 0.18 mM/kg IV given over 6 hours (0.01 – 0.03 mM/kg/hr). Recheck serum phosphorous before continuing. Usually may stop therapy when serum phosphorous level reaches 2 mg/dl. (Hardy and Adams 1989)
- b) Cats: For severe hypophosphatemia in diabetic ketoacidosis: Using potassium phosphate give 0.01 – 0.03 mM/kg/hr for 6 hours IV. Recheck serum phosphorous before continuing. In order to provide enough potassium without inducing hyperphosphatemia, supply 50–75% of patient's potassium using potassium chloride and the remainder as potassium phosphate. (Peterson and Randolph 1989)
- c) Correct underlying cause if possible. If serum phosphorus concentration is >1.5 mg/dl and unlikely to decrease further, no treatment is usually necessary. If <1.5 mg/dl, clinical signs or hemolysis present, treat. Also, consider treating during the first 24 hours of therapy for DKA. Goal of therapy is to maintain serum phosphorus >2 mg/dl without causing hyperphosphatemia. Oral phosphate supplementation is preferred; either a buffered phosphate laxative (e.g., Phospho-Soda), balanced commercial diet or milk. Severe hypophosphatemia is treated with intravenous therapy: Using either potassium phosphate (3 mMol phosphate/mL and 4.4 mEq potassium/mL) or sodium phosphate (if potassium supplementation is contraindicated; 3 mMol phosphate/mL and 4 mEq sodium/mL) give 0.01 – 0.03 mMol/kg/hr preferably by CRI. Avoid hyperphosphatemia. Monitor serum phosphorus every 6–8 hours and adjust dose. (Nelson and Elliott 2003b)
- d) In treating diabetic ketoacidosis, 1/3 of the IV potassium should be administered as potassium phosphate, particularly in small dogs and cats who are most susceptible to hemolysis

caused by hypophosphatemia. Use caution as over supplementation of phosphorus can result in metastatic calcification and hypocalcemia. (Greco 2007b)

- e) Cats with DKA and a serum phosphorus of <2 mg/dL: CRI of potassium phosphate at 0.03 – 0.06 mMol/kg/hr; severe cases of hypophosphatemia (<1 mg/dL) may require doses as high as 0.12 – 0.2 mMol/kg/hr. Recheck phosphorus after 6–12 hours. Alternatively may provide half the potassium requirements as KCl and half as K Phos. (Waddell 2007b)

Monitoring

- Serum inorganic phosphate (phosphorous)
- Other electrolytes, including calcium

Chemistry

Potassium phosphate injection is a combination of 224 mg monobasic potassium phosphate and 236 mg dibasic potassium phosphate. The pH of the injection is 6.5 and has an osmolarity of 7357 mOsm/L.

Sodium phosphate injection is a combination of 276 mg monobasic sodium phosphate and 142 mg dibasic sodium phosphate. The pH of the injection is 5.7 and has an osmolarity of about 7000 mOsm/L.

Because commercial preparations are a combination of monobasic and dibasic forms, prescribe and dispense in terms of mmoles of phosphate.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, store potassium or sodium phosphate injection at room temperature; protect from freezing.

Phosphates may be physically **incompatible** with metals such as calcium and magnesium.

Potassium phosphate injection is reportedly physically **compatible** with the following intravenous solutions and drugs: amino acids 4%/dextrose 25%, D₁₀LRS, D₁₀Ringer's, Dextrose 2.5%–10% injection, sodium chloride 0.45%–0.9%, magnesium sulfate, metoclopramide HCl, and verapamil HCl.

Potassium phosphate injection is reportedly physically **incompatible** with the following solutions or drugs: D_{2.5} in half normal Ringer's or LRS, D₅ in Ringer's, D₁₀/sodium chloride 0.9%, Ringer's injection, LRS, and dobutamine HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

There are no parenteral phosphate-only products approved for veterinary medicine. There are several proprietary phosphate-containing products available that may also include calcium, magnesium, potassium, and/or dextrose; refer to the individual product's labeling for specific dosage information. Trade names for these products include: *Magnadex*®—Osborn, *Norcalciphos*®—SKB, *Cal-Dextro*® Special, and #2, (Fort Dodge), and *CMPK*®, and *Cal-Phos*® #2 (TechAmerica). They are legend (Rx) drugs.

HUMAN-LABELED PRODUCTS:

Potassium Phosphate Injection; each mL provides 3 mM of phosphate (99.1 mg/dl of phosphorous) and 4.4 mEq of potassium per mL in 5, 10, 15, 30, and 50 mL vials; generic; (Rx)

Sodium Phosphate Injection; each mL provides 3 mM of phosphate (93 mg/dl of phosphorous) and 4 mEq of sodium per mL in 10, 15, 30, and 50 mL vials; generic; (Rx)

PHYSOSTIGMINE SALICYLATE

(fye-zoh-*stig*-meen sah-lis-ah-layt) Antilirium®

CHOLINESTERASE INHIBITOR

Prescriber Highlights

- ▶ Cholinesterase inhibitor that may be used for the adjunctive treatment of ivermectin toxicity in dogs, as a provocative agent for the diagnosis of narcolepsy in dogs & horses, or as a treatment for anticholinergic toxicity
- ▶ Crosses into the CNS, so it is effective for treating central anticholinergic toxicity, but also increases the risks for central physostigmine toxic effects (e.g., seizures)
- ▶ Must be administered with direct patient supervision; toxic effects from this drug can be serious

Uses/Indications

Physostigmine has been used for the adjunctive treatment of ivermectin toxicity in dogs, as a provocative agent for the diagnosis of narcolepsy in dogs and horses, and as a treatment for anticholinergic toxicity. Because of the potential for serious adverse effects, use of physostigmine as an antidote is generally reserved for very serious toxicity affecting the CNS. Otherwise, safer alternatives such as neostigmine or pyridostigmine are preferred.

While physostigmine has been used to antagonize the CNS depressant effects of benzodiazepines in humans, it should not be used for this purpose because of the potential toxicity and non-specific action of physostigmine.

Pharmacology/Actions

Physostigmine reversibly inhibits the destruction of acetylcholine by acetylcholinesterase, thereby increasing acetylcholine at receptor sites. Because physostigmine is a tertiary amine, unlike the quaternary amine cholinesterase inhibitors neostigmine and pyridostigmine, it crosses the blood-brain barrier and inhibits acetylcholinesterase both centrally and peripherally. Pharmacologic effects include miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands). At higher dosages, cholinergic crisis can occur; seizures, bradycardia, tachycardia, asystole, nausea, vomiting, diarrhea, depolarizing neuromuscular block, pulmonary edema, and respiratory paralysis are possible.

Pharmacokinetics

Physostigmine is rapidly absorbed from the GI tract (no oral dosage form available), subcutaneous tissue or mucous membranes. After parenteral administration, physostigmine readily crosses the blood-brain barrier into the CNS. Peak effects occur within 5 minutes after IV administration; about 25 minutes after IM dosing. The majority of administered drug is rapidly destroyed via hydrolysis by cholinesterases. Very small amounts can be eliminated unchanged into the urine. Duration of pharmacologic effects can be from 30 minutes to 5 hours; average duration is 30–60 minutes.

Contraindications/Precautions/Warnings

Contraindications for humans and, presumably, animal patients include: prior hypersensitivity reactions to physostigmine or sulfites, bronchoconstrictive disease (asthma), gangrene, diabetes mellitus, cardiovascular disease, mechanical obstruction of the GI or urinary tract, any vagotonic state, or the concurrent use of choline esters (e.g., bethanechol, methacholine) or neuromuscular blocking agents (e.g., succinylcholine)—see Drug Interactions.

When physostigmine is used in the absence of anticholinergic toxicity or to treat tricyclic or tetracyclic antidepressant overdoses, there is an increased risk for cholinergic crisis.

Rapid IV administration increases the potential for bradycardia, hypersalivation, or seizures. In humans, it should be given intravenously at a slow, controlled rate not exceeding 1 mg/minute (adults) and 0.5 mg/min (children).

Because of the risks for toxicity, atropine should be readily available (see Overdosage).

Physostigmine injection contains benzyl alcohol which may be toxic in neonatal animals.

Adverse Effects

Adverse effects are a result of the drug's pharmacologic actions and, except for hypersensitivity reactions, are dose related depending upon concurrent anticholinergic effects secondary to anticholinergics on board. Pharmacologic effects include miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands). At higher dosages, cholinergic crisis can occur; seizures, bradycardia, tachycardia, asystole, nausea, vomiting, diarrhea, depolarizing neuromuscular block, pulmonary edema, and respiratory paralysis are possible.

Reproductive/Nursing Safety

Little information is available, but it would be expected that physostigmine would cross the placenta. Teratogenic effects (behavioral, biochemical and metabolic) have reportedly been observed in mice studies. Weigh the potential risks of using physostigmine during pregnancy versus its potential benefits. In humans, the FDA categorizes alendronate as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known if physostigmine enters milk, but it would unlikely pose much risk to nursing offspring.

Overdosage/Acute Toxicity

Overdoses or acute toxicity can be life-threatening (see Adverse Reactions), however, because of the short duration of effect, supportive care may be all that is required. Treatment of serious acute toxicity includes mechanical ventilation, repeated bronchial aspiration, and administration of IV atropine. Refer to the Atropine monograph for dosages for cholinergic toxicity. Readministration of atropine may be required. Pralidoxime (2-PAM) may be useful in reversing the ganglionic and skeletal muscle effects of physostigmine. Refer to the Pralidoxime monograph for more information. An animal poison control center may be helpful in assisting with case management.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving physostigmine and may be of significance in veterinary patients:

- **CHOLINE ESTERS** (bethanechol, carbachol, methacholine) or **ORGANO-PHOSPHATES**: Physostigmine may cause additive adverse effects
- **SUCCINYLCHOLINE**: Physostigmine (high doses) may cause muscle fasciculations or depolarization block (very high doses), which may be additive to the effects of succinylcholine-like neuromuscular blockers

Laboratory Considerations

None were noted

Doses

■ DOGS:

- To temporarily reverse the CNS effects of ivermectin toxicosis in support of the diagnosis: 1 mg (total dose) IV (Mealey 2006)
- To temporarily reverse the CNS effects of ivermectin toxicosis in support of the diagnosis: 1 mg (total dose)/12 hours IV. May reverse ivermectin-induced coma for 30–90 minutes. In comatose patients, it does not appear to induce seizures, but seizure-like activity can be observed in patients with only minor ataxia and confusion. (Estrada 2002)
- Provocative test for narcolepsy/cataplexy if feeding test (10 pieces of highly tasty food that the dog loves to eat in a row 12–24 inches apart; affected dogs will usually take 2 minutes or longer to eat the food and will have several attacks) is not successful: Physostigmine at 0.025 mg/kg IV, wait 9–15 minutes and observe response to stimulus (food test or similar). If clinical signs do not appear, may try a higher dose of 0.05 mg/kg as above. Subsequent testing can be done at doses of 0.075 mg/kg and 1 mg/kg as above. Increased severity of signs that may persist for 15–45 minutes in response to stimulus is indicative of cataplexy/narcolepsy. (Shell 2003b)

■ HORSES: (Note: RCI Class 3 drug)

- Provocative test in diagnosing cataplexy or narcolepsy: 0.05–0.1 mg/kg slow IV will precipitate a cataplectic attack within 3–10 minutes after administration in affected horses. Untoward effects may include colic or cholinergic stimulation. (Andrews and Matthews 2004).
- Provocative test in diagnosing cataplexy or narcolepsy: 0.06–0.08 mg/kg IV. Lack of positive response does not rule out diagnosis of narcolepsy. Diarrhea can occur and caution is advised as horse can cause colic. (Mayhew 2005b)

■ CATTLE:

- For reversal of tall larkspur (*Delphinium barbeya*) poisoning: 0.04–0.08 mg/kg IV rapidly; serial injections may be necessary. (Pfister, Panter et al. 1994)

Monitoring

- Direct patient supervision required for monitoring adverse effects
- Heart rate, blood pressure; monitor heart rhythm if heart rate is abnormal

Client Information

- This medication must be administered in a setting where direct veterinary supervision is available

Chemistry/Synonyms

Physostigmine salicylate is made from an extract of *Physostigma venenosum* (Calabar Bean) seeds. It occurs as white, shining, odorless, crystals or crystalline powder. Upon exposure to heat, light, air, or exposure to traces of metals for a long period, it develops a red tint. One gram is soluble in 75 mL of water and 16 mL of alcohol. The injection has a pH of 3.5–5.

Physostigmine salicylate may also be known as eserine salicylate, physostigmine monosalicylate and *Anticholium*®.

Storage/Stability/Compatibility

The injection (ampules) should be stored below 40°C and preferably between 15–30°C. Protect from light and freezing. Physostigmine is labeled for human use to be administered IV undiluted. It may be given via a Y-site or stopcock port on IV set, but it should not be added to IV solutions. IM dosing (although not approved) is not uncommon in humans.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Physostigmine Salicylate Injection: 1mg/mL in 2 mL ampules, also contains benzyl alcohol 2% and 0.1% sodium metabisulfite; *Antilirium*® (Forest), generic; (Rx)

PHYTONADIONE VITAMIN K₁

(fye-toe-na-dye-ohne) Vitamin K1, Mephyton®

ANTIDOTE, FAT SOLUBLE VITAMIN

Prescriber Highlights

- Used for the treatment of anticoagulant rodenticide toxicity, dicumarol toxicity associated with sweet clover ingestion in ruminants, sulfaquinoxaline toxicity, & in bleeding disorders associated with faulty formation of vitamin K-dependent coagulation factors
- Contraindications: Hypersensitivity; does not correct hypoprothrombinemia due to hepatocellular damage.
- Adverse Effects: Anaphylactoid reactions after IV administration, IM use may result in acute bleeding from the site of injection during the early stages of treatment. SC injections or oral dosages may be slowly or poorly absorbed in hypovolemic animals.
- May require 6–12 hours for effect
- Small gauge needles are recommended for use when injecting SC or IM

Uses/Indications

The principal uses of exogenously administered phytonadione is in the treatment of anticoagulant rodenticide toxicity. It is also used for treating dicumarol toxicity associated with sweet clover ingestion in ruminants, sulfaquinoxaline toxicity, and in bleeding disorders associated with faulty formation of vitamin K-dependent coagulation factors.

Pharmacology/Actions

Vitamin K₁ is necessary for the synthesis of blood coagulation factors II, VII, IX, and X in the liver. It is believed that Vitamin K₁ is involved in the carboxylation of the inactive precursors of these factors to form active compounds.

Pharmacokinetics

Phytonadione is absorbed from the GI tract in monogastric animals via the intestinal lymphatics, but only in the presence of bile salts. Oral absorption of phytonadione may be significantly enhanced by administration with fatty foods. The relative bioavailability of the drug is increased 4–5 times in dogs given canned dog food with the dose. After oral administration, increases in clotting factors may not occur until 6–12 hours later.

In humans, oral administration may be more rapidly absorbed than with SC administration.

Phytonadione may concentrate in the liver for a short period of time, but is not appreciably stored in the liver or other tissues.

Only small amounts are distributed across the placenta in pregnant animals. Exogenously administered phytonadione enters milk. The elimination of Vitamin K₁ is not well understood.

Contraindications/Precautions/Warnings

Many veterinary clinicians state that the intravenous use of phytonadione is contraindicated because of increased risk of anaphylaxis development, and while intravenous phytonadione is used in human medicine and several intravenous dosage regimens are outlined below in the Dosage section, the FDA-CVM has warned to avoid administering the drug IV. However, in human medicine, intravenous phytonadione is recommended (with caution) for severe bleeding associated with very high INR. Phytonadione is contraindicated in patients hypersensitive to it or any component of its formulation.

Vitamin K does not correct hypoprothrombinemia due to hepatocellular damage.

Adverse Effects

Anaphylactoid reactions have been reported following IV administration of Vitamin K₁; use with extreme caution (See Contraindications above). Intramuscular administration may result in acute bleeding from the site of injection during the early stages of treatment. Small gauge needles are recommended for use when injecting SC or IM. Subcutaneous injections or oral dosages may be slowly or poorly absorbed in animals that are hypovolemic.

Because 6–12 hours may be required for new clotting factors to be synthesized after phytonadione administration, emergency needs for clotting factors must be provided by giving blood products.

Reproductive/Nursing Safety

Phytonadione crosses the placenta only in small amounts, but its safety has not been documented in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Vitamin K is excreted in maternal milk, but is unlikely to have negative effects in nursing offspring.

Overdosage/Acute Toxicity

Phytonadione is relatively non-toxic, and it would be unlikely that toxic clinical signs would result after a single overdosage. However, refer to the Adverse Effects section for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phytonadione and may be of significance in veterinary patients:

- **ANTIBIOTICS, ORAL:** Although chronic antibiotic therapy should have no significant effect on the absorption of phytonadione, these drugs may decrease the numbers of vitamin K producing bacteria in the gut
- **MINERAL OIL:** Concomitant administration of oral mineral oil may reduce the absorption of oral vitamin K.
- **WARFARIN:** As would be expected, phytonadione antagonizes the anticoagulant effects of coumarin (and indanedione agents). There are many drugs that may prolong or enhance the effects of anticoagulants and antagonize some of the therapeutic effects of phytonadione, including: **phenylbutazone, aspirin, chloramphenicol, sulfonamides diazoxide, allopurinol, cimetidine, metronidazole, anabolic steroids, erythromycin, ketoconazole, propranolol, and thyroid drugs.**

Doses

■ DOGS & CATS:

For adjunctive therapy of acute liver failure:

- a) 1–5 mg/kg PO or SC q24h (Rosanski 2002)

For anticoagulant rodenticide toxicity:

- a) For known warfarin, fumarin, pindone, or valone ingestions: 1 mg/kg PO once daily for 4–6 days.

For known bromadiolone or brodifacoum ingestions: 2.5 mg/kg PO once daily usually for 2–3 weeks (bromadiolone duration unknown).

For known diphacinone or chlorphacinone ingestions: 2.5–5 mg/kg PO for 3–4 weeks.

Note: Usual dosages and duration—use oral route (with one teaspoon of canned dog food) if animal not vomiting, otherwise SC route preferred over IV. Therapy must be continued for as long as rodenticide is inhibiting vitamin K₁ epoxide recycling. (Felice and Murphy 1995)

- b) For acute cases: Handle animal gently. Avoid IM injections; give fresh, whole blood transfusion 10–20 mL/kg IV (first half rapidly, then at 20 drops/minute). Give oxygen if hypoxic; if dyspneic consider radiographs and thoracentesis for intrathoracic hemorrhage. Then give phytonadione as below.

For subacute cases: Give phytonadione at 2–3 mg/kg SC q12h for large dogs and 5 mg/kg SC q12h for small dogs and cats. Repeat until coagulation times are normal. Follow with oral phytonadione at 2.5–3 mg/kg PO divided three times daily for 4–6 days if short acting coumarin (e.g., warfarin) or up to 30 days for long-acting agents. (Grauer and Hjelle 1988)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs: 1–10 mg/kg IM (Adamcak and Otten 2000)

■ CATTLE:

For anticoagulant rodenticide toxicity:

- a) Initially 0.5–2.5 mg/kg IV in D₅W at a rate of 10 mg/minute. Subsequent doses may be given IM or SC. Second generation agents may require 3–4 weeks of treatment. (Bailey 1986b)
- b) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D₅W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

- c) For acute hypoprothrombinemia with hemorrhage: 0.5–2.5 mg/kg IV, not to exceed 10 mg/minute in mature animals and 5 mg/minute in newborn and very young animals.

For non-acute hypoprothrombinemia: 0.5–2.5 mg/kg IM or SC (Label directions; *Veda-K₁*®—Vedco)

For sweet clover (dicumarol) toxicity:

- a) Give blood if necessary, then phytonadione 1 mg/kg IV or IM; repeat 2–3 times daily for 2 days. (Osweiler and Ruhr 1986)

■ HORSES:

For warfarin (or related compounds) toxicity:

- a) 500 mg SC q4–6h until one-stage prothrombin time (OSPT) returns to normal control values. Whole blood or fresh plasma may also be necessary early in the course of treatment. (Byars 1987)
- b) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D₅W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

■ SWINE:

For warfarin (or related compounds) toxicity:

- 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D₅W/saline and give very slowly (not to exceed 5 mg/minute). (Upton 1988)

■ SHEEP & GOATS:

For warfarin (or related compounds) toxicity:

- 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D₅W/saline and give very slowly (not to exceed 5 mg/minute). (Upton 1988)

■ BIRDS:

For hemorrhagic disorders:

- 0.25–0.5 mL/kg IM of the 10 mg/mL injectable product. Commonly used before surgery where hemorrhage is anticipated. (McDonald 1989)
- 0.2–2.5 mg/kg IM as needed; usually only 1–2 injections are required. May also be used prophylactically when amprolium and sulfas are administered. (Clubb 1986)

Monitoring

- Clinical efficacy (lack of hemorrhage)
- One-stage prothrombin time (OSPT); INR

Client Information

- Because it may take several weeks to eliminate some of the anti-coagulant rodenticides from the body, clients must be counseled on the importance of continuing to administer the drug (phytonadione) for as long as instructed or renewed bleeding may occur.
- Unless otherwise instructed, oral phytonadione should be administered with food, preferably foods high in fat content.
- During therapy, animals should be kept quiet whether at home or hospitalized.

Chemistry/Synonyms

A naphthoquinone derivative identical to naturally occurring vitamin K₁, phytonadione occurs as a clear, yellow to amber, viscous liquid. It is insoluble in water, slightly soluble in alcohol and soluble in lipids.

Phytonadione may also be known as: methylphytylnaphthochinonum, phylloquinone, phytomenadionum, phytomenadione, vitamin K₁, *AmTech*®, *Glakay*®, *Aqua-Mephyton*®, *K1*®, *K-Caps*®, *K-Chews*®, *K-Ject*®, *KP*®, *Kanakion*®, *Kanavit*®, *Kavit*®, *Kaytwo*®, *Kaywan*®, *Kenadion*®, *Konakion*®, *Konakion Novum*®, *Mephyton*®, *Pertix-Solo*®, *Veda-K1*, *Vikatron*®, *Vita-Jec*®, or *Vitamion K*®.

Storage/Stability/Compatibility

Phytonadione should be protected from light at all times, as it is quite sensitive to light. If used as an intravenous infusion, the container should be wrapped with an opaque material. Tablets and capsules should be stored in well-closed, light-resistant containers.

Because most veterinary clinicians state that phytonadione is contraindicated for intravenous use; consult specialized references or a hospital pharmacist for more specific information on compatibility of phytonadione with other agents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Phytonadione Oral Capsules: 25 mg; *K-Caps*® (Butler), *Veda-K1*® Capsules (Vedco), *Veta-K1*® (Bimeda), *Vitamin K1* (Phoenix Pharmaceutical, RXV); (Rx) Labeled for use in dogs and cats.

Phytonadione Oral Capsules: 50 mg; *Vitamin K1 Double Strength*® (Phoenix); (Rx) Labeled for use in dogs.

Phytonadione Oral Tablets, Chewable: 25 mg, 50 mg; *Vitamin K1 Chewable*® (V.E.T.), *Vitamin K1 Chewable*® (Pala-Tech), *K-Chews*® (Butler); (Rx). Products may be labeled for use in dogs and cats.

Phytonadione Aqueous Colloidal Solution for Injection: 10 mg/mL in 30 mL and 100 mL vials; *AmTech*® *Vitamin K1* (IVX), *K-Ject*® (Butler), *Veda-K1*® Injection (Vedco), *Vita-Jec*® (RXV), *Vitamin K1* (Vet Tek, Bimeda, Neogen, Phoenix Pharmaceutical), (Rx) Labeled for use dogs, cats, cattle, calves, horses, swine, sheep, and goats. No withdrawal times listed.

HUMAN-LABELED PRODUCTS:

Phytonadione Tablets: 5 mg; *Mephyton*® (Merck); (Rx)

Phytonadione Injection, Emulsion: 2 mg/mL (aqueous colloidal solution) & 10 mg/mL in 0.5 mL & 1 mL amps; generic (Hospira); (Rx)

PIMOBENDAN

(pi-moe-ben-den) Vetmedin®

INODILATOR

Prescriber Highlights

- Oral drug that may be useful in treatment of congestive heart failure in dogs
- Limited clinical experience, particularly in North America; many ongoing studies being performed
- May increase risks for arrhythmias

Uses/Indications

Pimobendan is used to treat dogs with congestive heart failure secondary to dilated cardiomyopathy or chronic mitral valve insufficiency (CMVI).

Pharmacology/Actions

Pimobendan is a so-called inodilator; it has both inotropic and vasodilator effects. Pimobendan usually decreases heart rate (negative chronotrope) in animals with CHF. Its inotropic effects occur via inhibition of phosphodiesterase III (PDE-III) and by increasing intracellular calcium sensitivity in the cardiac contractility apparatus. Cardiac contractility is enhanced without an increase in myocardial oxygen consumption, as pimobendan does not increase intracellular calcium levels. Its vasodilator effects are via vascular PDE-III inhibition and both arterial and venous dilation occur.

Pharmacokinetics

In dogs, following a single oral administration of 0.25 mg/kg pimobendan peak levels of the parent compound and the active metabolite were observed 1–4 hours post-dose (mean: 2 and 3 hours, respectively). Food decreased the bioavailability of an aqueous solution of pimobendan, but the effect of food on the absorption of pimobendan from chewable tablets is unknown. The steady-state volume of distribution of pimobendan is 2.6 L/kg. Protein binding of pimobendan and the active metabolite in dog plasma is >90%. Pimobendan is oxidatively demethylated to a pharmacologically active metabolite which is then conjugated with sulfate or glucuronic acid and excreted mainly via feces. Clearance of pimobendan is approximately 90 mL/min/kg, and the terminal elimination half-lives of pimobendan and the active metabolite are approximately 0.5 hours and 2 hours, respectively. Plasma levels of pimobendan and the active metabolite were below quantifiable levels by 4 and 8 hours respectively after oral administration.

In humans with heart failure, pimobendan is rapidly absorbed with peak levels occurring in less than one hour after dosing. The volume of distribution was about 3.2 L/kg; clearance about 25 mL/min/kg. Terminal half-life is slightly less than 3 hours.

Contraindications/Precautions/Warnings

Pimobendan is contraindicated in animals hypersensitive to it, with hypertrophic cardiomyopathy, aortic stenosis, or any other condition where an augmentation of cardiac output is inappropriate for functional or anatomic reasons. It should be used with caution in patients with uncontrolled cardiac arrhythmias.

The label states the drug has not been evaluated in dogs younger than 6 months of age, dogs with congenital heart defects, diabetes mellitus or other serious metabolic diseases, dogs used for breeding, or pregnant or lactating bitches.

Adverse Effects

Because clinical experience with this drug is still limited, the adverse effect profile is still being developed. In a US field trial (56 day), the adverse effect incidence (at least one occurrence reported per dog) was: poor appetite (38%), lethargy (33%), diarrhea (30%), dyspnea (29%), azotemia (14%), weakness and ataxia (13%), pleural effusion (10%), syncope (9%), cough (7%), sudden death (6%), ascites (6%), and heart murmur (3%).

In a study comparing cardiac adverse effects of pimobendan with benazepril (Chetboul, Lefebvre et al. 2007), dogs with mitral valve regurgitation had increases in systolic function but also developed worsening mitral valve disease and specific mitral valve lesions (acute hemorrhages, endocardial papilloform hyperplasia on the dorsal surfaces of the leaflets, and infiltration of *chordae tendinae* by glycosaminoglycans) not seen in the benazepril group. The authors recommend that patients with mitral valve disease that are treated chronically with pimobendan be regularly and cautiously examined for any worsening mitral valvular lesions and regurgitation.

There is some evidence that pimobendan may increase the development of arrhythmias. Atrial fibrillation or increased ventricular ectopic beats have been reported in dogs on pimobendan, but because cardiomyopathy can cause arrhythmias, a causative effect has not been fully established. A trial of pimobendan in humans with heart failure demonstrated an increased mortality rate while on the drug, but this result has not been duplicated in canine studies.

Reproductive/Nursing Safety

The label states the drug has not been evaluated in dogs used for breeding, or pregnant or lactating bitches. When pimobendan was given in high dosages (300 mg/kg) to pregnant laboratory animals, increased resorptions occurred. Rabbits given 100 mg/kg showed no adverse fetal effects.

No information on the safety of pimobendan during nursing was located.

Overdosage/Acute Toxicity

No specific information was located. In case of an animal overdose, contact an animal poison control center.

Drug Interactions

In field trials, the drug is labeled as being used safely with furosemide, digoxin, enalapril, atenolol, nitroglycerin, hydralazine, diltiazem, antiparasitic products (including heartworm preventative), antibiotics, famotidine, theophylline, levothyroxin, diphenhydramine, hydrocodone, metoclopramide and butorphanol.

The U.K. label states that “pimobendan-induced increase in contractility of the heart are attenuated in the presence of the calcium antagonist **verapamil** and the beta-antagonist **propranolol**.” It is assumed that other drugs in these categories (e.g., diltiazem, atenolol) may also have effect.

Milrinone, a human drug that also inhibits phosphodiesterase, has been used with a variety of other drugs (e.g., cardiac glycosides, lidocaine, hydralazine, prazosin, quinidine, nitroglycerin, furosemide, warfarin, spironolactone, heparin, potassium) without apparent problems, but because pimobendan also increases calcium sensitivity, comparing the two drugs may not be fully informative.

Laboratory Considerations

No laboratory interactions or special considerations were located.

Doses

■ DOGS:

- For management of the signs of mild, moderate or severe congestive heart failure due to AV valve insufficiency or dilated cardiomyopathy: 0.5 mg/kg total daily dose. Divide daily dose into two portions that are not necessarily equal (using whole and half tablets) and administer approximately 12 hours apart. (Label directions; *Vetmedin*®—B-I)
- For treatment of congestive heart failure secondary to myxomatous mitral valve disease (MMVD): 0.4–0.6 mg/kg PO divided twice daily (Lombard 2004)
- For treatment of heart failure secondary to dilated cardiomyopathy or chronic mitral valve insufficiency: 0.25 mg/kg PO twice daily (O’Grady, Minors et al. 2004)
- 0.2–0.6 mg/kg PO divided q12h (U.K. Label directions; *Vetmedin*®—BI; 2003)

Monitoring

■ Cardiovascular parameters used to monitor heart function, including ECG (rate/rhythm), blood pressure, echo studies, clinical signs, etc.

Client Information

- Give medication approximately one hour before feeding.
- Clients should understand that there is limited clinical experience with this drug, that there may be risks (arrhythmias) associated with its use, and that pimobendan is a treatment, and not a cure for heart failure.
- Compliance with the veterinarian’s instructions is essential.
- Keep out of reach of children.

Chemistry/Synonyms

A benzimidazole-derivative phosphodiesterase inhibitor, pimobendan occurs as a white or slightly yellowish, hygroscopic powder. It is practically insoluble in water and slightly soluble in acetone or methyl alcohol. Pimobendan’s chemical name is: 4,5-Dihydro-6-[2-(p-methoxyphenyl)-5-benzimidazolyl]-5-methyl-3(2H)pyridazinone. It has a molecular weight of 334.4.

Pimobendan may also be known as: UDCG-115, *Acardi*®, and *Vetmedin*®.

Storage/Stability

Unless otherwise labeled, pimobendan chewable tablets or capsules should be stored at room temperature below 25°C (77°F) in a dry place.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Pimobendan Chewable Tablets: 1.25 mg, 2.5 mg and 5 mg: *Vetmedin*® (B-I); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS: None**PIPERACILLIN SODIUM**

(*pype-er-ah-sill-in*) Pipracil®

EXTENDED SPECTRUM PENICILLIN**Prescriber Highlights**

- ▶ Extended-action penicillin, with good gram-negative spectrum, including many strains of *Pseudomonas*
- ▶ Limited experience in veterinary medicine, but appears quite safe
- ▶ Also available with a beta-lactamase inhibitor (tazobactam); see the next monograph

Uses/Indications

Although veterinary experience is limited with piperacillin or piperacillin/tazobactam, these drugs have expanded coverage against many bacteria and may be suitable for empiric use until culture and susceptibility data are available, or for surgical prophylaxis when gram-negative or mixed aerobic/anaerobic infections are concerns.

Pharmacology/Actions

Piperacillin is a bactericidal, extended action acylaminopenicillin that inhibits septum formation and cell wall synthesis in susceptible bacteria. It has a wide spectrum of activity against many aerobic and anaerobic gram-positive (including many enterococci) and gram-negative bacteria. It has a similar spectrum of activity as the aminopenicillins, but with additional activity against several gram-negative organisms of the family Enterobacteriaceae, including many strains of *Pseudomonas aeruginosa*. Like the aminopenicillins, it is susceptible to inactivation by beta-lactamases. The addition of a beta-lactamase inhibitor (tazobactam) in the product *Zosyn*® (see next monograph), increases piperacillin's spectrum of activity against many beta lactamase producing strains of bacteria.

Pharmacokinetics

Limited information is available for veterinary species. In mares, piperacillin has an elimination half-life of about 7 hours. IM bioavailability is 86% and protein binding about 19%.

In humans, piperacillin is not appreciably absorbed from the gut so it must be administered parenterally. After IM administration peak levels occur in about 30 minutes. The drug exhibits low protein binding and has a volume of distribution of 0.1L/kg. It is widely distributed into many tissues and fluids including lung, gall-bladder, intestinal mucosa, uterus, bile, and interstitial fluid. With inflamed meninges, piperacillin levels in the CSF are approximately 30% those in serum. If meninges are normal, CSF concentrations are only about 6% of serum levels. Piperacillin crosses the placenta and is distributed into milk in low concentrations. Piperacillin is metabolized somewhat in the liver to a desethyl metabolite that has only minimal antibacterial activity. Piperacillin is primarily (68%) eliminated unchanged in the urine via active tubular secretion and glomerular filtration; it is also excreted in the bile. Elimination half-life in humans is approximately one hour.

Contraindications/Precautions/Warnings

Piperacillin should not be used in patients with documented hypersensitive reactions to a beta-lactam.

Because of sodium content, high dosages of piperacillin may adversely affect patients with cardiac failure or hypernatremic conditions.

Dosage adjustment may be required in patients with significantly decreased renal function (CrCl <40 mL/min).

Adverse Effects

Piperacillin is generally well tolerated. Hypersensitivity reactions are possible. Local effects (thrombophlebitis, etc.) associated with intravenous injection or pain after IM injection may occur. Alterations in gut flora may lead to antibiotic-associated diarrhea.

In humans, piperacillin has caused coagulation abnormalities on occasion, particularly in patients with renal failure. Very high doses may cause neurotoxicity (seizures); again, these are more likely in patients with diminished renal function. Superinfections with *Clostridium difficile* have been reported rarely.

Reproductive/Nursing Safety

Piperacillin is thought relatively safe to use during pregnancy. No teratogenic effects have been attributed to it in either humans or laboratory animals. In humans, the FDA categorizes piperacillin as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Piperacillin is distributed in milk in low concentrations; it is likely safe to use during nursing.

Overdosage/Acute Toxicity

Single overdoses are unlikely to pose much risk although very large overdoses may cause vomiting, diarrhea, or neurotoxicity. Dogs receiving up to 800 mg/kg/day of piperacillin/tazobactam for 6 months demonstrated no serious toxic effects. Doses at 400 mg/kg/day or greater caused some transient effects to the liver (glycogen granules in the cytoplasm and increases in smooth endoplasmic reticulum in hepatocytes) that were mostly reversed after one month.

Treatment for overdoses, if required, is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperacillin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES (amikacin, gentamicin, tobramycin):** *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. Beta-lactam antibiotics, however, can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **ANTICOAGULANTS:** Because piperacillin may rarely affect platelets, increased monitoring of coagulation parameters is suggested for patients on heparin or warfarin
- **METHOTREXATE:** Piperacillin may increase MTX serum levels
- **PROBENECID:** Can reduce the renal tubular secretion of piperacillin thereby maintaining higher systemic levels for longer periods; this potential "beneficial" interaction requires further investigation before dosing recommendations can be made for veterinary patients
- **VECURIUM:** Piperacillin may prolong neuromuscular blockade

Laboratory Considerations

- **Urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®): Piperacillin may cause false-positive results; tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by piperacillin
- **Aminoglycoside serum quantitative analysis:** As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- **Direct antiglobulin (Coombs') tests:** False-positive results may occur
- **Urine protein:** May produce false-positive urine protein results with the sulfosalicylic acid and boiling test, nitric acid test, or the acetic acid test. Strips using bromophenol blue reagent (e.g., *Multi-Stix*®) do not appear to be affected by high levels of penicillins in the urine.

Doses

■ DOGS/CATS:

- a) For bacteremia with or without endocarditis: 30 mg/kg IV q6h for 7–14 days. (Calvert and Wall 2006)
- b) For respiratory infections: 25–50 mg/kg IV q8h. (Greene and Reinero 2006)
- c) Dogs: For systemic treatment of otitis media or proliferative otitis externa complicated by gram-negative (especially *Pseudomonas*) bacteria: 20 mg/kg SC three times daily. (Bloom 2006d)

■ BIRDS:

- a) For *Bordetella avium* infections: 150 mg/kg IM q8–12h; minimum treatment period is two weeks. (Flammer 2006)
- b) For susceptible infections: 100 mg/kg IM two to three times daily. (Antinoff 2004)

■ HORSES:

- a) For susceptible infections: 15–50 mg/kg IV or IM q6–12h. (Bertone and Horspool 2004)

■ REPTILES:

- a) For susceptible infections: 100 mg/kg route not specified q48h. (Antinoff 2004)
- b) Snakes: 100 mg/kg IM q24h (Mader 2004)

Monitoring

- Efficacy for the infection treated (WBC, clinical signs, etc.)

Client Information

- Limited experience in veterinary medicine
- Best suited for inpatient use

Chemistry/Synonyms

Piperacillin sodium occurs as a white or almost white, hygroscopic powder. It is freely soluble in water or alcohol. A 40% solution has a pH of 5–7.

Piperacillin sodium for injection contains 42.5 mg (1.85 mEq) sodium per gram.

Piperacillin may also be known as: piperacillinum, BL-P 1908, Cl 867, CL 227 193, T 12220, TA 058, *Pipracil*®, and *Pipril*®.

Storage/Stability/Compatibility

Piperacillin powder for injection vials should be stored at controlled room temperature (20–25°C).

Conventional vials should be reconstituted with 5 mL of diluent per gram of piperacillin. Suitable diluents include 0.9% sodium chloride, sterile water for injection, D5W, and bacteriostatic saline or water for injection. Once reconstituted, further dilute for intravenous infusion with 50–150 mL of 0.9% sodium chloride, LRS (must be given within 2 hours) or D5W. IV infusion of diluted products should be over at least 30 minutes. IV infusion from the contents of the reconstituted vials should be administered over at least 3–5 minutes to reduce the chance for vein irritation.

Once reconstituted, vials should be used within 4 hours of initial puncture. The manufacturer recommends not freezing reconstituted vials. IV bags (50–150 mL) containing further diluted product are stable for up to 24 hours at room temperature and one week if refrigerated. As no preservatives are used, sterility is not assured in stored reconstituted products.

For IM use, 5 mL of 0.5% or 1% lidocaine injection (without epinephrine) may be added to a 2 gram vial and used immediately.

Do not mix with aminoglycosides. Intravenous admixture solutions containing potassium, clindamycin, or hydrocortisone sodium succinate are reported **compatible** with piperacillin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Piperacillin Sodium Injection (powder for reconstitution): 2, 3, & 4 g (as base) vials, 40 g bulk vials; generic (American Pharmaceutical Partners); (Rx)

PIPERACILLIN SODIUM + TAZOBACTAM

(*pyp*e-er-ah-sill-in; tay-zoh-*bak*-tam) Zosyn®

EXTENDED SPECTRUM PENICILLIN + BETA-LACTAMASE INHIBITOR

Prescriber Highlights

- Extended action parenteral penicillin with a beta lactamase inhibitor; has increased spectrum of activity when compared with piperacillin alone, but is more expensive
- Limited experience or research in veterinary medicine, but appears quite safe

Uses/Indications

Although veterinary experience is limited with piperacillin or piperacillin/tazobactam, these drugs have expanded coverage against many bacteria and may be suitable for empiric use until culture and susceptibility data are available, or for surgical prophylaxis when gram-negative or mixed aerobic/anaerobic infections are concerns.

Pharmacology/Actions

For information on piperacillin, refer to the preceding monograph. Tazobactam irreversibly binds to beta-lactamases thereby “protecting” the beta-lactam ring of piperacillin from hydrolysis. When

tazobactam is combined with piperacillin, it extends piperacillin's spectrum of activity to those bacteria that produce beta-lactamases of Richmond-Sykes types II-V that would otherwise render it ineffective. It has slightly more activity than either clavulanate or sulbactam against some Type I beta-lactamases.

Tazobactam has minimal antibacterial activity when used alone, but in combination with piperacillin, synergistic effects may result. It is more potent than sulbactam and, unlike clavulanic acid, does not induce chromosomal beta-lactamases at serum concentrations achieved.

Pharmacokinetics

For information on the pharmacokinetics of piperacillin, refer to the previous monograph; tazobactam's pharmacokinetics generally mirrors that of piperacillin. In dogs, piperacillin reduced the renal clearance of tazobactam, presumably due to competition for tubular secretion.

Contraindications/Precautions/Warnings

Piperacillin/tazobactam should not be used in patients with documented hypersensitive reactions to a beta-lactam or beta-lactamase inhibitor.

Because of sodium content, high dosages of piperacillin/tazobactam may adversely affect patients with cardiac failure or hypertremic conditions.

Dosage adjustment may be required in patients with significantly decreased renal function (CrCl <40 mL/min).

Adverse Effects

Piperacillin/tazobactam is generally well tolerated. Hypersensitivity reactions are possible. Local effects (thrombophlebitis, etc.) associated with intravenous injection may occur. Alterations in gut flora may lead to antibiotic-associated diarrhea.

In humans, piperacillin has caused coagulation abnormalities on occasion, particularly in patients with renal failure. Very high doses may cause neurotoxicity (seizures); again, this is more likely in patients with diminished renal function. Superinfections with *Clostridium difficile* have been rarely reported.

Reproductive/Nursing Safety

Piperacillin/tazobactam is thought relatively safe to use during pregnancy. No teratogenic effects have been attributed to either drug in either humans or laboratory animals. In humans, the FDA categorizes piperacillin/tazobactam as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Piperacillin is distributed in milk in low concentrations. It is not known if tazobactam enters milk. This drug combination is likely safe to use during nursing.

Overdosage/Acute Toxicity

Single overdoses are unlikely to pose much risk although very large overdoses may cause vomiting, diarrhea, or neurotoxicity. Dogs receiving up to 800 mg/kg/day of piperacillin/tazobactam for 6 months demonstrated no serious toxic effects. Doses at 400 mg/kg/day or greater caused some transient effects to the liver (glycogen granules in the cytoplasm and increases in smooth endoplasmic reticulum in hepatocytes) that were mostly reversed after one month.

Treatment for overdoses, if required, is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperacillin/tazobactam and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (amikacin, gentamicin, tobramycin): *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. Beta-lactam antibiotics however, can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **ANTICOAGULANTS**: Because piperacillin may rarely affect platelets, increased monitoring of coagulation parameters is suggested for patients on heparin or warfarin.
- **METHOTREXATE**: Piperacillin may increase MTX serum levels
- **PROBENECID**: Can reduce the renal tubular secretion of both piperacillin and tazobactam, thereby maintaining higher systemic levels for a longer period of time; this potential "beneficial" interaction requires further investigation before dosing recommendations can be made for veterinary patients.
- **VECURIUM**: Piperacillin may prolong neuromuscular blockade

Laboratory Considerations

- **Urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®): Piperacillin may cause false-positive results. Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by piperacillin.
- **Aminoglycoside serum quantitative analysis**: As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- **Direct antiglobulin (Coombs') tests**: False-positive results may occur
- **Urine protein**: Piperacillin may produce false-positive urine protein results with the sulfosalicylic acid and boiling test, nitric acid test, or the acetic acid test. Strips using bromophenol blue reagent (e.g., *Multi-Stix*®) do not appear to be affected by high levels of penicillins in the urine.

Doses

■ DOGS / CATS:

- a) For single-agent therapy of intra-abdominal sepsis: 50 mg/kg IV or IM q4–6h for 5–7 days; dose extrapolated from human dosage with limited studies in dogs or cats. (Greene 2006)
- b) For bacterial sepsis in dogs: 3.375 g (total dose per dog) IV q6h or 4.5 g (total dose per dog) IV q8h for 7 days. (Greene, Hartmann et al. 2006)

■ BIRDS:

- a) For susceptible infections: Reconstitute to 200 mg/mL and administer at 100 mg/kg IM q8–12h; for severe polymicrobial bacteremia give 100 mg/kg IV q6h; for preoperative orthopedic or coelomic surgery: 100 mg/kg IM q12h. (Nemetz and Lennox 2006)

Monitoring

- Efficacy for the infection treated (CBC, clinical signs, etc.)

Client Information

- Limited experience in veterinary medicine
- Best suited for inpatient use

Chemistry/Synonyms

Piperacillin sodium/tazobactam sodium occurs as a white or almost white, cryodesiccated powder. Tazobactam is structurally related to sulbactam and a penicillanic acid sulfone derivative. The commercially available piperacillin/tazobactam injection contains 2.79 mEq of sodium and 0.25 mg of EDTA per gram of piperacillin.

Tazobactam may also be known as: CL 298741, or YTR 830H. Piperacillin may also be known as piperacillinum, BL-P 1908, CL 867, CL 227193, T 12220, and TA 058. International trade names for piperacillin/tazobactam include: *Tazobac*®, *Tazocin*®, *Zosyn*® and others.

Storage/Stability/Compatibility

Piperacillin/tazobactam injection vials and *ADD-Vantage* vials should be stored at controlled room temperature (20–25°C).

Conventional vials should be reconstituted with 5 mL of diluent per gram of piperacillin. Suitable diluents include 0.9% sodium chloride, sterile water for injection, and bacteriostatic saline or water for injection. Once reconstituted, further dilute for intravenous infusion with 50–150 mL of 0.9% sodium chloride, LRS (reformulated product only—see below) or D5W. IV infusion should be over at least 30 minutes.

Once reconstituted, vials should be used immediately. It is recommended to discard after 24 hours if kept at room temperature or 48 hours if stored in the refrigerator. The manufacturer recommends not freezing reconstituted vials. IV bags (50–150 mL) containing further diluted product are stable for up to 24 hours at room temperature and one week if refrigerated. As no preservatives are used, sterility is not assured in stored reconstituted products.

Zosyn® (piperacillin/tazobactam) injection underwent a formulation change in 2006. Sodium citrate (buffer) and EDTA (metal chelator) were added that made it **compatible** with lactated Ringer's injection and via simultaneous Y-site administration at specific concentrations of gentamicin and amikacin (but not tobramycin). This reformulated product has a yellow background behind the *Zosyn*® name on the label. Refer to the package insert for specific information on diluent and concentration compatibility.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Piperacillin Sodium & Tazobactam Injection (lyophilized powder for injection); *Zosyn*® (Wyeth); (Rx):

2.25 g (piperacillin 2 g/tazobactam 0.25 g) in vials and *ADD-Vantage*® vials; contains 4.69 mEq sodium

3.375 g (piperacillin 3 g/tazobactam 0.375 g) in vials and *ADD-Vantage*® vials; contains 7.04 mEq sodium

4.5 g (piperacillin 4 g/tazobactam 0.5 g) in vials and *ADD-Vantage*® vials; contains 9.36 mEq sodium

40.5 g bulk vials (piperacillin 36 g/tazobactam 4.5 g); in bulk vials; contains 84.5 mEq sodium

Also available in 3.375 g/50 mL and 4.5 g/100 mL premixed, frozen *Galaxy*® containers.

PIPERAZINE

(pi-per-a-zeen) Pipa-Tabs®

ANTIPARASITIC (ASCARIDS)

Prescriber Highlights

- Anthelmintic for ascarids in a variety of species
- Contraindications: Chronic liver, kidney disease, & gastrointestinal hypomotility.
- Caution: Seizure disorders, horses with heavy infestations of *P. equorum*
- Adverse Effects: Unlikely, but diarrhea, emesis, or ataxia possible

Uses/Indications

Piperazine is used for the treatment of ascarids in dogs, cats, horses, swine and poultry. Piperazine is considered safe to use in animals with concurrent gastroenteritis and during pregnancy.

Pharmacology/Actions

Piperazine is thought to exert “curare-like” effects on susceptible nematodes, thereby paralyzing or narcotizing the worm and allowing it to be passed out with the feces. The neuromuscular blocking effect is believed to be caused by blocking acetylcholine at the myoneural junction. In ascarids, succinic acid production is also inhibited.

Pharmacokinetics

Piperazine and its salts are reportedly readily absorbed from the proximal sections of the GI tract and the drug is metabolized and excreted by the kidneys. Absorptive, distribution, and elimination kinetics on individual species were not located.

Contraindications/Precautions/Warnings

Piperazine should be considered contraindicated in patients with chronic liver or kidney disease, and those with gastrointestinal hypomotility. There is some evidence in humans that high-dose piperazine may provoke seizures in patients with a history of seizures, or with renal disease.

If used in horses with heavy infestations of *P. equorum*, rupture or blockage of intestines is possible due to the rapid death and detachment of the worm.

Adverse Effects

Adverse effects are uncommon at recommended doses, but diarrhea, emesis, and ataxia may be noted in dogs or cats. Horses and foals generally tolerate the drug quite well, even at high dosage rates, but a transient softening of the feces may be seen. Other adverse effects have been seen at toxic dosages; refer to the Overdosage section below for more information.

Reproductive/Nursing Safety

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

No information was located on use during nursing, but it probably is safe to use.

Overdosage/Acute Toxicity

Acute massive overdosage can lead to paralysis and death, but the drug is generally considered to have a wide margin of safety. The oral LD₅₀ of piperazine adipate in mice is 11.4 g/kg.

In cats, adverse effects occur within 24 hours after a toxic dose is ingested. Emesis, weakness, dyspnea, muscular fasciculations of ears, whiskers, tail and eyes, rear limb ataxia, hypersalivation, depression, dehydration, head-pressing, positional nystagmus and slowed pupillary responses have all been described after toxic ingestions. Many of these effects may also be seen in dogs after toxic piperazine ingestions.

Treatment is symptomatic and supportive. If ingestion was recent, use of activated charcoal and a cathartic has been suggested. Intravenous fluid therapy and keeping the animal in a quiet, dark place is recommended. Recovery generally takes place within 3–4 days.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperazine and may be of significance in veterinary patients:

- **CHLORPROMAZINE:** Although data conflicts, piperazine and chlorpromazine may precipitate seizures if used concomitantly
- **LAXATIVES:** The use of purgatives (laxatives) with piperazine is not recommended as the drug may be eliminated before its full efficacy is established
- **PYRANTEL/MORANTEL:** Piperazine and pyrantel/morantel have antagonistic modes of action and should generally not be used together

Laboratory Considerations

- Piperazine can have an effect on **uric acid** blood levels, but references conflict with regard to the effect. Both falsely high and low values have been reported; interpret results cautiously.

Doses

CAUTION: Piperazine is available in several salts that contain varying amounts of piperazine base (see Chemistry below). Many of the doses listed below do not specify what salt (if any) is used in the dosage calculations. If the dose is in question, refer to the actual product information for the product you are using.

■ DOGS:

For treatment of ascarids (**Note:** Because larval stages in the host's tissues may not be affected by the drug, many clinicians recommend retreating about 2–3 weeks after the first dose):

- a) 45–65 mg of base/kg PO; for pups less than 2.5 kg: 150 mg maximum. (Cornelius and Roberson 1986)
- b) 110 mg/kg PO (Chiapella 1988)
- c) 100 mg/kg PO; repeat in 3 weeks (Morgan 1988)
- d) 20–30 mg/kg PO once (Davis 1985)
- e) 110 mg/kg PO; repeat in 21 days (Kirk 1989)
- f) 45–65 mg/kg (as base) PO (Roberson 1988b)

■ CATS:

For treatment of ascarids (**Note:** Because larval stages in the host's tissues may not be affected by the drug, many clinicians recommend retreating about 2–3 weeks after the first dose):

- a) 45–65 mg of base/kg PO; 150 mg maximum (Cornelius and Roberson 1986)
- b) 110 mg/kg PO (Chiapella 1988)
- c) 100 mg/kg PO; repeat in 3 weeks (Morgan 1988)
- d) 20–30 mg/kg PO once (Davis 1985)

- e) 110 mg/kg PO; repeat in 21 days (Kirk 1989)
- f) 45–65 mg/kg (as base) PO (Roberson 1988b)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Mice, rats, hamsters, gerbils, and rabbits: For pinworms: Piperazine citrate in drinking water at 3 grams/liter for 2 weeks. (Burke 1999)
- b) Rabbits: For Pinworms: Piperazine citrate 100 mg/kg PO q24h for 2 days. Piperazine adipate: Adults: 200–500 mg/kg PO q24h for 2 days. Young rabbits: 750 mg/kg, PO once daily for 2 days. Wash the perianal area. (Ivey and Morrissey 2000)
- c) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: For pinworms/tapeworms using piperazine citrate: 2–5 mg/mL drinking water for 7 days, off 7 days and repeat (Adamcak and Otten 2000)

■ HORSES:

There are combination products available for use in horses (see Dosage Forms/Preparations section) that contain piperazine with increased efficacy against nematodes and other helminths. Refer to the individual products' package insert for more information.

- a) 110 mg/kg (base) PO; repeat in 3–4 weeks. Retreating at 10-week intervals for *P. equorum* infections in young animals is recommended. (Roberson 1988b)
- b) 200 mg/kg, PO. Maximum of 80 grams in adults, 60 grams in yearlings, and 30 grams in foals. (Brander, Pugh, and Bywater 1982)

■ CATTLE, SHEEP & GOATS:

Because of high resistance of many nematode species to piperazine, it is rarely used alone in these species.

■ SWINE:

For *Ascaris suum* and *Oesophagostomum*:

- a) 0.2–0.4% in the feed, or 0.1–0.2% in the drinking water. All medicated water or feed must be consumed within 12 hours, so fasting or withholding water overnight may be beneficial to ensure adequate dosing; retreat in 2 months. Safe in young animals, and during pregnancy. Drug withdrawal times not determined for swine. (Paul 1986)
- b) 110 mg/kg (as base). Citrate salt usually used in feed as a one-day treatment, and hexahydrate in drinking water. Dose must be consumed in 8–12 hours. Withholding water or feed the previous night may be beneficial. (Roberson 1988b)

■ BIRDS:

- a) For ascarids in poultry (not effective in psittacines): 100–500 mg/kg PO once; repeat in 10–14 days (Clubb 1986)
- b) For nematodes: Piperazine citrate: 45–100 mg/kg single dose or 6–10 grams/gallon for 1–4 days. In raptors: 100 mg/kg. In parakeets and canaries: 0.5 mg/gram (Stunkard 1984)
- c) For *Ascaridia galli* in poultry: 32 mg/kg (as base) (approximately 0.3 grams for each adult) given in each of 2 successive feedings or for 2 days in drinking water. Citrate or adipate salts are usually used in feed and the hexahydrate in drinking water. (Roberson 1988b)

Monitoring

- Clinical and/or laboratory efficacy
- Adverse effects

Client Information

- Clients should be instructed to administer only the amount prescribed and to relate any serious adverse effects to the veterinarian.

Chemistry/Synonyms

Piperazine occurs as a white, crystalline powder that may have a slight odor. It is soluble in water and alcohol. Piperazine is available commercially in a variety of salts, including citrate, adipate, phosphate, hexahydrate, and dihydrochloride. Each salt contains a variable amount of piperazine (base): adipate (37%), chloride (48%), citrate (35%), dihydrochloride (50–53%), hexahydrate (44%), phosphate (42%), and sulfate (46%).

Piperazine may also be known as diethylendiamin, dispermin, hexahydropropyrazin, piperazinum, and *Pipa-Tabs*®.

Storage/Stability

Unless otherwise specified by the manufacturer, piperazine products should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Piperazine Dihydrochloride tablets equivalent to 50 mg or 250 mg base. *Pipa-Tabs*® (Vet-A-Mix); (Rx). Approved for use in dogs and cats.

Additional OTC products and combination products may be available for a variety of species. Products and/or trade names include: *Alfalfa Pellet Horse Wormer*, *Tasty Paste*® Dog & Puppy Wormer, *Wonder Wormer*™ for Horses, *D-Worm*™ Liquid Wormer for Cats and Dogs, *Wazine*®-17, *Wazine*®-34, *Hartz*® Advanced Care™ Liquid Wormer, *Hartz*® Advanced Care™ Once-a-Month® Wormer for Kittens and Cats, *Hartz*® Advanced Care™ Once-a-Month® Wormer for Dogs, *Sergeant's*® Vetscription® Worm-Away® for Cats, *Sergeant's*® Vetscription® Sure Shot® Liquid Wormer for Cats & Kittens, *Piperazine-17 Medicated*, *WormEze*™ Canine Anthelmintic, *WormEze*™ Feline Anthelmintic Paste, *WormEze*™ Canine & Feline Anthelmintic Liquid.

HUMAN-LABELED PRODUCTS: None

PIRLIMYCIN HCL

(per-li-mye-sin) *Pirsue*®

INTRAMAMMARY LINCOSAMIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Lincosamide antibiotic for intramammary use in dairy cattle
- ▶ Milk withdrawal (at labeled doses) = 36 hours after last treatment; Meat withdrawal (at labeled doses) = 9 days

Uses/Indications

Pirlimycin mastitis tubes are indicated for the treatment of clinical and subclinical mastitis caused by susceptible organisms in lactating dairy cattle.

Pharmacology/Actions

Like other lincosamides, pirlimycin acts by binding to the 50S ribosomal subunit of susceptible bacterial RNA, thus interfering with bacterial protein synthesis. It is primarily active against gram-positive bacteria, including a variety of species of staphylococcus (*S. aureus*, *S. epidermidis*, *S. chromogenes*, *S. hyicus*, *S. xylosus*), streptococcus (*S. agalactiae*, *S. dysgalactiae*, *S. uberis*, *S. bovis*) and *Enterococcus faecalis*.

Organisms with a MIC of ≤ 2 mcg/mL are considered susceptible, and organisms with a MIC value of 4 mcg/mL are considered resistant. If using a 2 microgram disk for Kirby-Bauer plate testing, a zone diameter of ≤ 12 mm indicates resistance and a diameter of ≥ 13 mm indicates susceptibility.

Pharmacokinetics

Little information is available; the manufacturer states that the drug penetrates the udder well and is absorbed systemically from the udder and then secreted into the milk of all four quarters. Tissue levels in treated quarters of pirlimycin are approximately 2–3 times those found in the extracellular fluid.

Contraindications/Precautions/Warnings

No information was noted.

Adverse Effects

No adverse effects, including udder irritation have been reported thus far.

Milk from untreated quarters must be disposed of during withdrawal time as residues may be detected from untreated quarters.

Reproductive/Nursing Safety

No information was noted.

Overdosage/Acute Toxicity

No data was located.

Drug Interactions

Because **erythromycin** and **clindamycin** have shown antagonism *in vitro*, this could also occur with pirlimycin.

Laboratory Considerations

- The established tolerance of pirlimycin in milk is 0.4 ppm.

Doses

■ CATTLE:

- a) Lactating Dairy Cattle: Infuse one syringe into each affected quarter; repeat one time in 24 hours. See label directions for more specific information on administrative techniques. (Package Insert; *Pirsue*®—Upjohn)

Monitoring

- Efficacy
- Withdrawal periods

Client Information

- Be sure clients understand dosage recommendations and withdrawal periods.
- Milk from untreated quarters must be disposed of during withdrawal time as residues may be detected from untreated quarters.

Chemistry/Synonyms

Pirlimycin HCl is a lincosamide antibiotic. It has a molecular weight of 465.4.

Pirlimycin HCl may also be known as U-57930E and *Pirsue*®.

Storage/Stability

Store syringes at or below 25°C (77°F); protect from freezing.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Pirlimycin HCl Sterile Solution 50 mg (equiv. to free base) in a 10 mL disposable teat syringe; *Pirsue® Aqueous Gel* (Pfizer); (Rx). Approved for use in lactating dairy cattle. Milk withdrawal (at labeled doses) = 36 hours after last treatment; Meat withdrawal (at labeled doses) = 9 days

HUMAN-LABELED PRODUCTS: None

PIROXICAM

(peer-ox-i-kam) Feldene®

NON-STEROIDAL ANTIINFLAMMATORY,
ANTI-TUMOR

Prescriber Highlights

- ▶ NSAID with antiinflammatory & antitumor (indirect) activity
- ▶ Contraindications: Hypersensitivity or severely allergic to aspirin or other NSAIDs. Extreme Caution: Active, or a history of GI ulcer disease or bleeding disorders. Caution: Severely compromised cardiac function
- ▶ Use in cats is controversial; use with extreme caution
- ▶ Adverse Effects: GI ulceration & bleeding, renal papillary necrosis, & peritonitis
- ▶ Probably safer NSAIDs available for pain/inflammation for dogs & cats

Uses/Indications

In dogs, piroxicam may be beneficial in reducing the pain and inflammation associated with degenerative joint disease, but there are safer alternatives available. Its primary use is in dogs as adjunctive treatment of bladder transitional cell carcinoma. It may also be of benefit in squamous cell carcinomas, mammary adenocarcinoma, and transmissible venereal tumor (TVT). There is some use of it in cats for its anti-tumor effects, but it must be used with extreme caution in this species.

Pharmacology/Actions

Like other non-steroidal antiinflammatory agents, piroxicam has antiinflammatory, analgesic, and antipyretic activity. The drug's antiinflammatory activity is thought to be primarily due to its inhibition of prostaglandin synthesis, but additional mechanisms (e.g., superoxide formation inhibition) may be important. As with other NSAIDs, piroxicam can affect renal function, cause GI mucosal damage, and inhibit platelet aggregation.

Piroxicam's antitumor effects are believed to be due to its action on the immune system and not because of direct effects on tumor cells.

Pharmacokinetics

After oral administration, piroxicam is well absorbed from the gut. While the presence of food will decrease the rate of absorption, it will not decrease the amount absorbed. It is not believed that antacids significantly affect absorption.

After single oral doses in cats, piroxicam is well absorbed with an oral bioavailability of about 80%. Peak levels occur in approximately 3 hours. Elimination half-life after intravenous dosing is about 12 hours.

Piroxicam is highly bound to plasma proteins. In humans, synovial levels are about 40% of those found in plasma. Maternal milk concentrations are only about 1% of plasma levels.

In humans, piroxicam has a very long plasma half-life (about 50 hours). The drug is principally excreted as metabolites in the urine after hepatic biotransformation.

Contraindications/Precautions/Warnings

Piroxicam is contraindicated in patients hypersensitive to it or who are severely allergic to aspirin or other NSAIDs. It should be used only when its potential benefits outweigh the risks in patients with active or history of GI ulcer disease or bleeding disorders. Because peripheral edema has been noted in some human patients, it should be used with caution in patients with severely compromised cardiac function.

Piroxicam has not been evaluated for use in cats. It must be used with extreme caution, if at all, in this species.

Adverse Effects

Like other NSAIDs used in dogs, piroxicam has the potential for causing significant GI ulceration and bleeding. The therapeutic window for the drug is very narrow in dogs, as doses as low as 1 mg/kg given daily have caused significant GI ulceration, renal papillary necrosis, and peritonitis. Other adverse effects reported in humans and potentially possible in dogs include: CNS effects (headache, dizziness, etc.), otic effects (tinnitus), elevations in hepatic function tests, pruritus and rash, and peripheral edema. Renal papillary necrosis has been seen in dogs at post-mortem but, apparently, clinical effects have not been noted with these occurrences.

Reproductive/Nursing Safety

Animal studies have not demonstrated any teratogenic effects associated with piroxicam. The drug is excreted into milk in very low concentrations (about 1% found in maternal plasma). In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) If using in the third trimester or near delivery in humans, the FDA categorizes all NSAIDs as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Most NSAIDs are excreted in maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity

There is limited information available, but dogs may be more sensitive to the drugs ulcerative effects than are humans.

There were 87 exposures to piroxicam reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 76 were dogs with 8 showing clinical signs and 11 were cats with 3 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, abdominal pain, diarrhea, lethargy and abnormal colored feces. Common findings in cats recorded in decreasing frequency included vomiting.

As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis should be considered. Patients ingesting

significant overdoses should be monitored carefully and treated supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piroxicam and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (**gentamicin**, **amikacin**, etc.): Increased risk for nephrotoxicity
- **ANTICOAGULANTS** (**heparin**, **LMWH**, **warfarin**): Increased risk for bleeding possible
- **ASPIRIN**: When aspirin is used concurrently with piroxicam, plasma levels of piroxicam could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with piroxicam cannot be recommended.
- **BISPHOSPHONATES** (**alendronate**, etc.): May increase risk for GI ulceration
- **CISPLATIN**: Piroxicam may potentiate the renal toxicity of cisplatin when used in combination
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **FUROSEMIDE**: Piroxicam may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (e.g., **phenytoin**, **valproic acid**, **oral anti-coagulants**, **other antiinflammatory agents**, **salicylates**, **sulfonamides**, and the **sulfonylurea antidiabetic agents**): Because piroxicam is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution

Laboratory Considerations

- Piroxicam may cause falsely elevated **blood glucose** values when using the glucose oxidase and peroxidase method using ABTS as a chromogen.

Doses

■ DOGS:

As an adjunctive therapy of transitional cell carcinomas, squamous cell carcinomas, and palliative therapy for other neoplastic diseases:

- a) 0.3 mg/kg PO once a day (Frimberger and London 2003)
- b) 0.3 mg/kg PO once a day. Give with food. Consider adding misoprostol at 3 mcg/kg, PO q8h for dogs who tolerate NSAIDs poorly. Discontinue if severe irritation or ulceration occurs. Treat ulcers and if signs abate, may resume piroxicam with misoprostol. (Frimberger 2000)
- c) For adjuvant therapy for splenic hemangiosarcoma (stage II): Etoposide 50 mg/m² PO once daily for 3 weeks, alternating 3 week cycles with cyclophosphamide at 12.5–25 mg/m² PO once daily. Piroxicam is given at 0.3 mg/kg PO every day. Continue until disease recurrence and progression is noted. (Lana, U'ren et al. 2007)
- d) For transitional cell carcinoma after laser ablation of the primary tumor: Mitoxantrone at IV 5 mg/m² every 3 weeks for 4 treatments. Piroxicam was given at a dosage of 0.3 mg/kg PO once daily for the remaining life of the dog. (Upton, Tanger et al. 2006)

As an antiinflammatory/analgesic:

- a) 0.3 mg/kg PO every other day (q48h) (Boothe 1992), (Hansen 2003b)

■ CATS:

As an adjunctive therapy of transitional cell carcinomas, but may be of limited utility in squamous cell carcinoma:

- a) 0.3 mg/kg PO q24–72h. Gastric protectants (misoprostol, H₂ blockers sucralfate, omeprazole) may be useful to prevent/teat GU ulceration. Use with caution in patients with pre-existing renal disease and avoid use with other nephrotoxic drugs. Fluid supplementation may be warranted. (Smith 2003a)

■ RABBITS, RODENTS, SMALL MAMMALS:

Rabbits: For fracture associated limb swelling:

- a) 0.1–0.2 mg/kg PO q8h for 3 weeks (Ivey and Morrissey 2000)

Monitoring

- Adverse Effects (particularly GI bleeding)
- Liver function and renal function tests should be monitored occasionally with chronic use

Client Information

- Have clients monitor for GI ulceration/bleeding (anorexia, tarry stools, etc.).
- Do not exceed dosage recommendations without veterinarian's approval. It has been suggested to give the drug with food to reduce GI upset potential.

Chemistry/Synonyms

An oxican derivative non-steroidal antiinflammatory agent, piroxicam occurs as a white, crystalline solid. It is sparingly soluble in water. Piroxicam is structurally not related to other non-steroidal antiinflammatory agents.

Piroxicam may also be known as: CP-16171, piroxicamum or PIRO; many trade names are available.

Storage/Stability

Capsules should be stored at temperatures less than 30°C in tight, light-resistant containers. When stored as recommended, capsules have an expiration date of 36 months after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Piroxicam Capsules: 10 mg & 20 mg; *Feldene*® (Pfizer); generic; (Rx)

Plasma-Lyte—see the section on intravenous fluids in the Appendix

POLYSULFATED GLYCOSAMINOGLYCAN (PSGAG)

(*pol-ee-sulf-ayte-ed glye-kose-a-meen-ohe-glye-kan*)

Adequan®, Chondroprotect®

PROTEOLYTIC ENZYME INHIBITOR;
CHONDROPROTECTANT

Prescriber Highlights

- ▶ Proteolytic enzyme inhibitor used IM or intra-articularly for non-infectious &/or traumatic joint dysfunction & associated lameness of the carpal joints in horses & non-infectious degenerative &/or traumatic arthritis in dogs
- ▶ Contraindications: Intra-articular injection if patient hypersensitive to PSGAG. Should not be used in place of other treatments when infection suspected or present, or when surgery or joint immobilization required
- ▶ Adverse Effects: IM use: Unlikely. Intra-articular: Post-injection inflammation possible. *Dogs:* Dose-related inhibition of coagulation/hemostasis possible.

Uses/Indications

PSGAG administered either IM or IA is indicated for the treatment of non-infectious and/or traumatic joint dysfunction and associated lameness of the carpal joints in horses. Some studies have indicated that PSGAG is much less effective in joints where there has been acute trauma but no degradative enzymes present.

It is also approved for the control of signs associated with non-infectious degenerative and/or traumatic arthritis in dogs.

Pharmacology/Actions

In joint tissue, PSGAG inhibits proteolytic enzymes that can degrade proteoglycans (including naturally occurring glycosaminoglycans), thereby preventing or reducing decreased connective tissue flexibility, resistance to compression, and resiliency. By acting as a precursor, PSGAG increases the synthesis of proteoglycans, reduces inflammation by reducing concentrations of prostaglandin E₂ (released in response to joint injury) and increases hyaluronate concentrations in the joint, thereby restoring synovial fluid viscosity.

Pharmacokinetics

PSGAG is deposited in all layers of articular cartilage and preferentially taken up by osteoarthritic cartilage. When administered IM, articular levels will with time exceed those found in the serum. After IM injection, peak joint levels are reached in 48 hours and persist up to 96 hours.

Contraindications/Precautions/Warnings

PSGAG is contraindicated for intra-articular administration in patients hypersensitive to it. While the manufacturer states there are no contraindications for IM use of the drug, the drug should not be used in place of other therapies in cases where infection is present or suspected, or in place of surgery or joint immobilization where indicated.

Some clinicians feel that PSGAG should not be used within one week of arthrotomy in dogs, because it may cause increased bleeding. This effect apparently has not been confirmed in the literature, however.

Adverse Effects

Adverse effects are unlikely when using the IM route. Intra-articular administration may cause a post-injection inflammation (joint pain, effusion, swelling, and associated lameness) secondary to sensitivity reactions, traumatic injection technique, overdosage, or the number or frequency of the injections. Treatment consisting of antiinflammatory drugs, cold hydrotherapy, and rest is recommended. Although rare, joint sepsis secondary to intraarticular injection is possible; strict aseptic technique should be employed to minimize this occurrence.

In dogs, a dose-related inhibition of coagulation/hemostasis has been described.

Reproductive/Nursing Safety

Reproductive studies have apparently not been performed; use with caution during pregnancy or in breeding animals (the manufacturer does not recommend use in breeding animals).

In humans, the FDA categorizes glycosaminoglycans as category *B* for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether glycosaminoglycans are excreted in maternal milk, but is unlikely to be of significant concern.

Overdosage/Acute Toxicity

Doses five times those recommended (2.5 grams) given IM to horses twice weekly for 6 weeks revealed no untoward effects. Approximately 2% of horses receiving overdoses (up to 1250 mg) IA showed transient clinical signs associated with joint inflammation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving PSGAG and may be of significance in veterinary patients:

While specific drug interactions have not been detailed to date, using this product in conjunction with either steroids or non-steroidal antiinflammatory agents could mask the signs and clinical signs associated with septic joints.

There is some concern that since PSGAG is a heparin analog that it should not be used in conjunction with other NSAIDs or other anticoagulants. Clinical significance remains unclear, but use together with caution.

Doses

■ HORSES:

- a) For IM administration: 500 mg IM (of IM product) every 4 days for 28 days. Thoroughly cleanse injection site before injecting. Do not mix with other drugs or chemicals. (Package Insert; Adequan® I.M.)

For intra-articular administration: 250 mg (of IA product) IA once a week for 5 weeks. Joint area should be shaved, and cleansed as if a surgical procedure, prior to injecting. Do not mix with other drugs or chemicals. (Package Insert; Adequan® I.A.)

- b) For IM injection: 500 mg IM every 3–4 days for a minimum of 4 and preferably, 7 treatments.

For intra-articular injection: As above; author recommends adding 125 mg of amikacin for injection into the IA injection to reduce potential for infection. (Nixon 1992)

DOGS:

For the treatment of non-infectious degenerative and/or traumatic arthritis:

- 4.4 mg/kg IM twice weekly for up to 4 weeks. (Label information; *Adequan® Canine*—Luitpold)
- 1.1–4.8 mg/kg IM every 4 days for six doses and then as needed (Kelly 1995)
- Osteoarthritis: 5 mg/kg IM twice a week (McLaughlin 2000)
- Osteoarthritis: 5 mg/kg IM once weekly (Hardie and Grauer 2007)

CATS:

As a chondroprotective drug:

- 1.1–4.8 mg/kg IM every 4 days for six doses and then as needed (Kelly 1995)
- 2 mg/kg IM every 3–5 days for 4 treatments; only anecdotal experience in cats. (Kerwin 2007)

RABBITS, RODENTS, SMALL MAMMALS:

- Rabbits: For arthritis:
2.2 mg/kg SC or IM every 3 days for 21–28 days, then once every 2 weeks (Ivey and Morrissey 2000)

Monitoring

- Efficacy
- Joint inflammation/infection if administered IA.

Client Information

- The IA product must be administered by veterinary professionals; the IM product could, with proper instruction, be administered by the owner.

Chemistry/Synonyms

Polysulfated glycosaminoglycan (PSGAG) is chemically similar to natural mucopolysaccharides found in cartilaginous tissues. PSGAG is reportedly an analog of heparin.

Polysulfated glycosaminoglycan is also known as PSGAG, *Adequan®* and *Chondroprotec®*.

Storage/Stability/Compatibility

Commercial products should be stored in a cool place 8–15°C (46–59°F). The manufacturer recommends discarding any unused portion from the vial or ampule and, also does not recommend mixing with any other drug or chemical.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Polysulfated Glycosaminoglycan for Intra-Articular Injection: 250 mg/mL in 1 mL single use vials, boxes of 6; *Adequan® I.A.* (Luitpold); (Rx). Approved for use in horses, (not in those intended for food).

Polysulfated Glycosaminoglycan for Intra-Muscular Injection: 100 mg/mL in 5 mL glass ampules or 5 mL vials, boxes of 4; *Adequan® I.M.* (Luitpold); (Rx). Approved for use in horses, (not in those intended for food).

Polysulfated Glycosaminoglycan for IM Injection: 100 mg/mL; *Adequan® Canine* (Luitpold); (Rx). Approved for use in dogs.

Polysulfated Glycosaminoglycan Topical Solution: sterile solution of 1000 mg in 10 mL vials. Approved for use on horses. No reported side effects. *Chondroprotec®* (Neogen) (Rx)

HUMAN-LABELED PRODUCTS: None

PONAZURIL

(poe-naz-yoor-ill) Marquis®

ANTIPROTOZOAL

Prescriber Highlights

- Equine approved triazine for treating EPM
- Adverse Effect profile not well established; in field trials: rashes, hives, blisters, or GI signs noted
- Treatment is relatively expensive

Uses/Indications

Ponazuril is indicated for the treatment of equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*.

Ponazuril could potentially be useful in treating *Neospora caninum* and *Toxoplasma* infections in dogs or cats.

Pharmacology/Actions

The triazine class of antiprotozoals are believed to target the “plastid” body, an organelle found in the members of the Apicomplexa phylum, including *Sarcocystis neurona*. *In vitro* levels required to kill *Sarcocystis neurona* range from 0.1–1 mcg/mL.

Pharmacokinetics

After daily (5 mg/kg) oral administration to horses, ponazuril reaches its peak serum levels in about 18 days and peak CSF levels in about 15 days. Peak CSF levels are about 1/20th (0.21 mcg/mL) those found in the serum. Elimination half-life from serum averages about 4.5 days.

Contraindications/Precautions/Warnings

None were noted. Before treating, other conditions that can cause ataxia should be ruled out.

Adverse Effects

Limited experience at time of writing. Field trials showed some animals developing blisters on nose and mouth or a rash/hives. Single animals developed diarrhea, mild colic or seizures.

Successful treatment may not negate all the clinical signs associated with EPM.

Keratoconjunctivitis sicca (KCS) has been reported in some dogs, especially those breeds with a predilection towards developing KCS or when the drug was given in overdose quantities.

Reproductive/Nursing Safety

Safety during pregnancy or in lactating mares has not been evaluated.

Overdosage/Acute Toxicity

Daily doses of up to 30 mg/kg (6X) primarily caused loose feces. Moderate edema of the uterine epithelium was noted on histopathology for female horses receiving the 6X dose.

Drug Interactions/Laboratory Considerations

None noted

Doses■ **DOGS, CATS:**

- a) For Neosporosis or Toxoplasmosis: 7.5–15 mg/kg PO once daily for 28 days. Dose extrapolated between doses for horses and mice. (Greene, Hartmann et al. 2006)
- b) For coccidiosis: Anecdotal, 15–30 mg/kg PO once or repeated after 7–10 days. (Hurley 2007)

■ **HORSES:**

For EPM:

- a) 5 mg/kg, PO once daily for 28 days. See the package insert for specific dosing instructions. (Package insert; *Marquis*®—Bayer)

Monitoring

- Clinical efficacy

Client Information

- For this drug to be effective it must be given as prescribed.
- Contact veterinarian if rashes, hives, blisters, or GI signs develop.
- Clients should be forewarned of the considerable expense associated with this drug and that clinical improvement may be marginal or not occur at all in some horses treated.

Chemistry/Synonyms

Related to other antiprotozoals such as toltrazuril, ponazuril is a triazine antiprotozoal (anticoecidial) agent. The commercially available oral paste is white to off-white in color and odorless; pH is 5.7–6.

Ponazuril may also be known as: ICI-128436, *Marquis*®, and *Ponalrestat*®.

Storage/Stability

Store the paste at room temperature (15–30°C).

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Ponazuril Oral Paste (15% w/w): 127-gram tubes; each gram of paste contains 150 mg of ponazuril; each syringe is enough to treat a 1200 lb. horse for 7 days. *Marquis*® (Bayer); (Rx). Not for use in horses intended for food.

HUMAN-LABELED PRODUCTS: None

Potassium Bromide—see Bromides

Potassium Iodide—see Iodide, Potassium

POTASSIUM CHLORIDE POTASSIUM GLUCONATE

(po-tass-ee-um) Cal-Dextro® K, Tumil-K®

ELECTROLYTE**Prescriber Highlights**

- Used for treatment or prevention of hypokalemia
- Contraindications: Hyperkalemia, renal failure or severe renal impairment, severe hemolytic reactions, untreated Addison's disease, acute dehydration, GI motility impairment (solid oral dosage forms)
- Caution: Patients on digoxin
- Adverse Effects: Hyperkalemia. Oral therapy: GI distress; IV therapy may be irritating to veins
- Intravenous potassium salts must be diluted before administering & drug must be given slowly
- Acid/base, hydration status important
- Drug Interactions

Uses/Indications

Potassium supplementation is used to prevent or treat potassium deficits. When feasible and appropriate, because it is generally safer, oral or nutritional therapy is generally preferred over parenteral potassium administration.

Pharmacology/Actions

Potassium is the principal intracellular cation in the body. It is essential in maintaining cellular tonicity; nerve impulse transmission; smooth, skeletal and cardiac muscle contraction; and maintenance of normal renal function. Potassium is also used in carbohydrate utilization and protein synthesis.

Pharmacokinetics

Potassium is primarily (80–90%) excreted via the kidneys with the majority of the remainder excreted in the feces. Very small amounts may be excreted in perspiration (animals with sweat glands).

Contraindications/Precautions/Warnings

Potassium salts are contraindicated in patients with hyperkalemia, renal failure or severe renal impairment, severe hemolytic reactions, untreated Addison's disease, and acute dehydration. Solid oral dosage forms should not be used in patients where GI motility is impaired. Use cautiously in digitalized patients (see Drug Interactions).

Because potassium is primarily an intracellular electrolyte, serum levels may not adequately reflect the total body stores of potassium. Acid-base balance may also mask the actual potassium picture. Patients with systemic acidosis conditions may appear to have hyperkalemia when, in fact, they may be significantly low in total body potassium. Conversely, alkalosis may cause a falsely low serum potassium value. Assess renal and cardiac function prior to therapy and closely monitor serum potassium levels. Supplementation should generally occur over 3–5 days to allow equilibration to occur between extracellular and intracellular fluids. Some clinicians feel that if acidosis is present or a concern, use potassium acetate, citrate or bicarbonate; if alkalosis is present, use potassium chloride.

Adverse Effects

The major problem associated with potassium supplementation is the development of hyperkalemia. Clinical signs associated with hyperkalemia can range from muscular weakness and/or GI disturbances to cardiac conduction disturbances. Clinical signs can be exacerbated by concomitant hypocalcemia, hyponatremia, or acidosis. Intravenous potassium salts must be diluted before administering and given slowly (see Doses).

Oral therapy can cause GI distress and IV therapy may be irritating to veins.

Reproductive/Nursing Safety

Monitored potassium supplementation is unlikely to have negative effects during pregnancy or lactation.

Overdosage/Acute Toxicity

Fatal hyperkalemia may develop if potassium salts are administered too rapidly IV or if potassium renal excretory mechanisms are impaired. Clinical signs associated with hyperkalemia are noted in the Adverse Effects section above. Treatment of hyperkalemia is dependent upon the cause and/or severity of the condition and can consist of: discontinuation of the drug with ECG, acid/base and electrolyte monitoring, glucose/insulin infusions, sodium bicarbonate, calcium therapy, and polystyrene sulfonate resin. It is suggested to refer to other references appropriate for the species being treated for specific protocols for the treatment of hyperkalemia.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving potassium and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **enalapril**): Potassium retention may occur; increased risk for hyperkalemia
- **DIGOXIN**: In patients with severe or complete heart block who are receiving digitalis therapy, it is often recommended not to use potassium salts
- **NSAIDS**: Oral potassium given with non-steroidal antiinflammatory agents may increase the risk of gastrointestinal adverse effects
- **POTASSIUM-SPARING DIURETICS** (e.g., **spironolactone**): Potassium retention may occur; increased risk for hyperkalemia

Doses

■ DOGS & CATS:

For hypokalemia:

- a) Intravenous replacement: If animal has normal renal function, IV KCl not to exceed 0.5 mEq/kg/hr. Use IV replacement very cautiously in animals with impaired renal function or in those receiving potassium-sparing diuretics.
Subcutaneous replacement: If IV use is unfeasible or rapid correction is unnecessary, may add KCl to SC fluids; do not exceed 30 mEq of potassium per liter.
Oral replacement: Potassium gluconate PO at a rate of 2.2 mEq per 100 calories of required energy intake or potassium gluconate elixir (20 mEq/mL) for dogs at 5 mL q8–12h PO (Bell and Osborne 1986)
- b) Oral using **Tumil-K®** (Virbac): 1/4 teaspoonful (2 mEq) per 4.5 kg body weight PO in food twice daily. Adjust dose as necessary. (Package insert; **Tumil-K®**—Virbac).
- c) Intravenous replacement: potassium chloride IV at a rate not to exceed 0.5 mEq/hour. Concentration of replacement fluid should exceed 60 mEq/L. Begin oral supplementation as soon as possible using potassium gluconate for dogs at a

dose of 2–44 mEq/day depending on body size; cats get 2–4 mEq/day. (Peres 2000)

- d) Potassium administration should be considered on the basis of how much potassium to administer to the patient, not how much to add to a bag of fluid. Dosages usually range from maintenance (0.05–0.1 mEq/kg/hour) to 0.5 mEq/kg/hour. (Hansen 2007c)

■ RUMINANTS:

For hypokalemia:

- a) In “downer” cows: 80 g sodium chloride and 20 g potassium chloride in 10 liters of water PO via stomach tube. Provide a bucket containing similar solution for cow to drink and another containing fresh water. (Caple 1986)
- b) 50 grams PO daily; 1 mEq/kg/hr IV drip (Howard 1986)
- c) For severe hypokalemia (<2.3 mEq/L) with severe muscle weakness or recumbency: Isotonic potassium chloride (11.5 grams of potassium chloride per 1 liter of sterile water) at a rate of 4 mL/kg/hour. Combined with large doses of oral potassium salts (i.e., 200 grams of KCl per day. (Smith 2006)

Monitoring

Level and frequency of monitoring associated with potassium therapy is dependent upon the cause and/or severity of hypokalemia, acid/base abnormalities, renal function, concomitant drugs administered, or disease states and can include:

- Serum potassium
- Other electrolytes
- Acid/base status
- Glucose
- ECG
- CBC
- Urinalyses

Chemistry/Synonyms

Potassium chloride occurs as either white, granular powder or as colorless, elongated, prismatic, or cubical crystals. It is odorless and has a saline taste. One gram is soluble in about 3 mL of water and is insoluble in alcohol. The pH of the injection ranges from 4–8. One gram of potassium chloride contains 13.4 mEq of potassium. A 2 mEq/mL solution has an osmolality of 4000 mOsm/L. Potassium chloride may also be known as KCl.

Potassium gluconate occurs as white to yellowish white, crystalline powder or granules. It is odorless, has a slightly bitter taste, and is freely soluble in water. One gram of potassium gluconate contains 4.3 mEq of potassium.

Potassium Chloride may also be known as: KCl, cloreto de potassio, E508, kalii chloridum, or kalium chloratum.

Potassium Gluconate may also be known as: E577, *K-G Elixir®*, *Kaon®*, *Kaylixir®*, *Potasoral®*, *Potassiject®*, *Potassium-Rougier®*, *Renakare®*, *Sopa-K®*, *Tumil-K®*, and *Ultra-K®*.

Storage/Stability/Compatibility

Potassium gluconate oral products should be stored in tight, light resistant containers at room temperature (15–30°C), unless otherwise instructed by the manufacturer.

Unless otherwise directed by the manufacturer, potassium chloride products should be stored in tight, containers at room temperature (15–30°C); protect from freezing.

Potassium chloride for injection is reportedly physically **compatible** with the following intravenous solutions and drugs (as an additive): all commonly used intravenous replacement fluids (not 10% fat emulsion), aminophylline, amiodarone HCl, bretylium tosylate, calcium gluconate, carbenicillin disodium, cephalothin sodium,

cephapirin sodium, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, corticotropin (ACTH), cytarabine, dimenhydrinate, dopamine HCl, erythromycin gluceptate/lactobionate, heparin sodium, hydrocortisone sodium succinate, isoproterenol HCl, lidocaine HCl, metaraminol bitartrate, methicillin sodium, methyl dopate HCl, metoclopramide HCl, nafcillin sodium, norepinephrine bitartrate, oxacillin sodium, oxytetracycline HCl, penicillin G potassium, phenylephrine HCl, piperacillin sodium, sodium bicarbonate, tetracycline HCl, thiopental sodium, vancomycin HCl, verapamil HCl, and vitamin B-complex with C.

Potassium chloride for injection **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: fat emulsion 10%, amikacin sulfate, dobutamine HCl, methylprednisolone sodium succinate (at Y-site), penicillin G sodium, and promethazine HCl (at Y-site). Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Potassium chloride for injection is reportedly physically **incompatible** with the following solutions or drugs: amphotericin B, diazepam (at Y-site), and phenytoin sodium (at Y-site).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are several products for parenteral use that contain potassium; refer to the tables in the appendix or individual proprietary veterinary products (e.g., *Cal-Dextro*® K—Fort Dodge) for additional information.

Potassium Chloride IV Solution: 2 mEq (149 mg) in 10 mL vials; *Potassiject*® (Butler); generic; (Rx)

Oral Products:

Potassium Gluconate Tablets: 2 mEq (468 mg). Labeled for use in cats and dogs; *Tumil-K*® (Virbac), *Renakare*® (Neogen); (Rx)

Potassium Gluconate Oral Powder: Each 0.65 gram 4 oz (1/4 teaspoonful) contains 2 mEq of potassium in 4 oz. Containers; *Renakare*® (Neogen); *Tumil-K*® (Virbac) (Rx). Labeled for use in dogs and cats.

Potassium Gluconate Gel: Each 2.34 gm (1/2 teaspoonful) contains 2 mEq of potassium in 5 oz tubes; *Tumil-K*® Gel (Virbac), *Renakare*® (Neogen) (Rx). Labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS: Not a complete list.

Parenteral Products:

Potassium Chloride for Injection Concentrate (**Must be diluted before administering**): 2 mEq/mL in 250 mL and 500 mL; 10 mEq in 5 mL, 10 mL, 50 mL and 100 mL vials & 5 mL additive syringes; 20 mEq in 10 mL and 20 mL vials, 10 mL additive syringes and amps; 30 mEq in 15 mL, 20 mL, 30 mL and 100 mL vials and 20 mL additive syringes; 40 mEq in 20 mL, 30 mL, 50 mL and 100 mL vials, 20 mL amps and additive syringes; 60 mEq and 90 mEq in 30 mL vials; generic; (Rx)

Potassium acetate for injection and potassium phosphate for injection (see Phosphate monograph) are also available. There are a multitude of human-labeled potassium salts for oral use available in several dosage forms; refer to human drug references for more information on these products. Tablets, controlled/sustained release tablets and capsules, effervescent tablets, liquids, and powder in varying strengths available; (OTC and Rx)

Potassium Citrate—see Citrate Salts

PRALIDOXIME CHLORIDE 2-PAM CHLORIDE

(pra-li-*dox*-eem) Protopam Chloride®

ANTIDOTE; CHOLINESTERASE REACTIVATOR

Prescriber Highlights

- Cholinesterase reactivator used for adjunctive treatment of organophosphate poisoning
- Contraindications: Hypersensitivity; generally not recommended for carbamate poisoning
- Caution: Renal impairment, patients receiving anticholinesterase agents for the treatment of myasthenia gravis
- Adverse Effects: Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, or laryngospasm
- Most-effective if given within 24 hours of exposure

Uses/Indications

Pralidoxime is used in the treatment of organophosphate poisoning, often in conjunction with atropine and supportive therapy.

Pharmacology/Actions

Pralidoxime reactivates cholinesterase that has been inactivated by phosphorylation secondary to certain organophosphates. Via nucleophilic attack, the drug removes and binds the offending phosphoryl group attached to the enzyme, which is then excreted.

Pharmacokinetics

Pralidoxime is only marginally absorbed after oral dosing; oral dosage forms are no longer available in the United States. It is distributed primarily throughout the extracellular water. Because of its quaternary ammonium structure, it is not believed to enter the CNS in significant quantities, but recent studies and clinical responses have led some to question this belief.

Pralidoxime is thought to be metabolized by the liver and excreted as both metabolite(s) and unchanged drug in the urine.

Contraindications/Precautions/Warnings

Pralidoxime is contraindicated in patients hypersensitive to it. Pralidoxime is generally not recommended for use in instances of carbamate poisoning because inhibition is rapidly reversible, but there is some controversy regarding this issue.

Pralidoxime should be used with caution in patients receiving anticholinesterase agents for the treatment of myasthenia gravis as it may precipitate a myasthenic crisis. It should also be used cautiously and at a reduced dosage rate in patients with renal impairment.

Adverse Effects

At usual doses, pralidoxime generally is safe and free of significant adverse effects. Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, and laryngospasm.

Pralidoxime must generally be given within 24 hours of exposure to be effective, but some benefits may occur, particularly in large exposures, if given within 36–48 hours.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in maternal milk; exercise caution.

Overdosage/Acute Toxicity

The acute LD₅₀ of pralidoxime in dogs is 190 mg/kg and, at high dosages, causes signs associated with its own anticholinesterase activity. Clinical signs of toxicity in dogs may be exhibited as muscle weakness, ataxia, vomiting, hyperventilation, seizures, respiratory arrest, and death.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pralidoxime and may be of significance in veterinary patients:

- **BARBITURATES:** Anticholinesterases can potentiate the action of barbiturates; use with caution.
- **CIMETIDINE, SUCCINYLCHOLINE, THEOPHYLLINE, RESERPINE, and RESPIRATORY DEPRESSANT DRUGS** (e.g., narcotics, phenothiazines): Use should be avoided in patients with organophosphate toxicity.

Doses

Note: Often used in conjunction with atropine; refer to that monograph and/or the references below for more information.

■ DOGS & CATS:

For organophosphate poisoning:

- a) Pralidoxime works best when combined with atropine. Pralidoxime at 20 mg/kg, 2–3 times a day. Initial dose may be given either IM or slow IV. Subsequent doses may be given IM or SC. (Refer to reference for more specific guidelines regarding adjunctive therapy) (Fikes 1990)
- b) 10–15 mg/kg IM or SC q8–12h; 36 hour minimum (Firth 2000)
- c) Give atropine first at 0.1 mg/kg IV, followed by an additional 0.3 mg/kg IM. Then pralidoxime at 50 mg/kg diluted in 10% glucose and administered via slow IV. If a severe poisoning and muscle weakness has not been relieved, may give another dose in one hour. For small dogs or cats, pralidoxime may be administered IM or IP. Reduce dose in presence of renal failure. Recovery should occur gradually over 48 hours. (El Bahri 2002)
- d) Dogs: 50 mg/kg; Cats 20 mg/kg. Give IV slowly or with fluids over a 30-minute period. Repeat in one hour if clinical signs persist and then q8h for 24–48 hours. Author recommends using pralidoxime in animals that are severely depressed, weak, and anorectic one or more days after exposure if not previously treated with pralidoxime. In animals that have clinical signs intensified (e.g., respiratory depression), reduce dose and give as repeated one-hour infusions every 4–8 hours in combination with atropine (0.04–0.4 mg/kg) once or as needed (Mount 1989)
- e) Cats: 20 mg/kg IM or IV within first 24 hours of exposure. May repeat q6–8h and combine with atropine or give separately. Do not use in carbamate toxicity. (Reid and Oehme 1989)

■ CATTLE:

Note: When used in food animals, FARAD recommends a 28 day meat and a 6 day milk withdrawal time. (Haskell, Payne et al. 2005)

For organophosphate poisoning:

- a) 25–50 mg/kg as a 20% solution IV over 6 minutes; or as a maximum of 100 mg/kg/day as an IV drip (Smith 1986)

■ HORSES:

For organophosphate poisoning:

- a) 20 mg/kg (may require up to 35 mg/kg) IV and repeat q4–6h (Oehme 1987c)

■ BIRDS:

For organophosphate poisoning:

- a) 10–20 mg/kg q8–12h (route not specified) with atropine (0.2–0.5 mg/kg IM q3–4h). (Jones 2007a)

Monitoring

- Pralidoxime therapy is monitored via the clinical signs associated with organophosphate poisoning. For more information, refer to one of the references outlined in the dosage section.

Client Information

- This agent should only be used with close professional supervision.

Chemistry/Synonyms

A quaternary ammonium oxime cholinesterase reactivator, pralidoxime chloride occurs as a white to pale yellow, crystalline powder with a pK_a of 7.8–8. It is freely soluble in water. The commercially available injection has a pH of 3.5–4.5 after reconstitution.

Pralidoxime Chloride may also be known as: 2-Formyl-1-methylpyridinium chloride oxime, 2-PAM, 2-PAM chloride, 2-PAMCl, 2-pyridine aldoxime methochloride and *Protopam*®.

Storage/Stability

Unless otherwise instructed by the manufacturer, pralidoxime chloride powder for injection should be stored at room temperature. After reconstituting with sterile water for injection, the solution should be used within a few hours. Do not use sterile water with preservatives added.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pralidoxime Chloride Powder for Injection: 1 g in 20 mL single-use vials; *Protopam*® Chloride (Wyeth-Ayerst); (Rx)

PRAZIQUANTEL

(pra-zi-kwon-tel) Droncit®

ANTICESTODAL ANTIPARASITIC

Prescriber Highlights

- ▶ Anticestodal anthelmintic also may be useful for some other parasites
- ▶ Contraindications: Puppies less than 4 weeks old or kittens less than 6 weeks old; hypersensitivity to the drug
- ▶ Adverse Effects: Uncommon after oral use; pain at injection site, anorexia, salivation, vomiting, lethargy, weakness, or diarrhea possible after using injectable

Uses/Indications

Praziquantel is indicated for (approved labeling) for the treatment of *Dipylidium caninum*, *Taenia pisiformis*, and *Echinococcus granulosus* in dogs, and *Dipylidium caninum* and *Taenia taeniaeformis* in cats. Fasting is not required nor recommended before dosing. A single dose is usually effective, but measures should be taken to prevent reinfection, particularly against *D. caninum*. Praziquantel can also be used for treating *Alaria* spp. in dogs and cats and *Spirometra mansonoides* infections in cats.

Praziquantel has been used in birds and other animals, but it is usually not economically feasible to use in large animals. In humans, praziquantel is used for schistosomiasis, other trematodes (lung, liver, intestinal flukes) and tapeworms. It is not routinely effective in treating *F. hepatica* infections in humans.

Combination products can give a wide spectrum of internal parasite control in a variety of species.

Pharmacology/Actions

Praziquantel's exact mechanism of action against cestodes has not been determined, but it may be the result of interacting with phospholipids in the integument causing ion fluxes of sodium, potassium and calcium. At low concentrations *in vitro*, the drug appears to impair the function of their suckers and stimulates the worm's motility. At higher concentrations *in vitro*, praziquantel increases the contraction (irreversibly at very high concentrations) of the worm's strobilla (chain of proglottids). In addition, praziquantel causes irreversible focal vacuolization with subsequent cestodal disintegration at specific sites of the cestodal integument.

In schistosomes and trematodes, praziquantel directly kills the parasite, possibly by increasing calcium ion flux into the worm. Focal vacuolization of the integument follows and the parasite is phagocytized.

Pharmacokinetics

Praziquantel is rapidly and nearly completely absorbed after oral administration, but there is a significant first-pass effect. Peak serum levels are achieved between 30–120 minutes in dogs.

Praziquantel is distributed throughout the body. It crosses the intestinal wall and across the blood-brain barrier into the CNS.

Praziquantel is metabolized in the liver to metabolites of unknown activity. It is excreted primarily in the urine; elimination half-life is approximately 3 hours in the dog.

Contraindications/Precautions/Warnings

The manufacturer recommends not using praziquantel in puppies less than 4 weeks old or in kittens less than 6 weeks old. However, a combination product containing praziquantel and febantel from the same manufacturer is approved for use in puppies and kittens of all ages. No other contraindications are listed for this compound from the manufacturer. In humans, praziquantel is contraindicated in patients hypersensitive to the drug.

Adverse Effects

When used orally, praziquantel can cause anorexia, vomiting, lethargy, or diarrhea in dogs, but the incidence of these effects is less than 5%. In cats, adverse effects were quite rare (<2%) in field trials using oral praziquantel, with salivation and diarrhea being reported.

A greater incidence of adverse effects has been reported after using the injectable product. In dogs, pain at the injection site, vomiting, drowsiness, and/or a staggering gait were reported from field trials with the drug. Some cats (9.4%) showed clinical signs of diarrhea, weakness, vomiting, salivation, sleepiness, transient anorexia, and/or pain at the injection site.

Reproductive/Nursing Safety

Praziquantel is considered safe to use in pregnant dogs or cats. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Praziquantel appears in maternal milk at a concentration of approximately 25% of that in maternal serum, but is unlikely to pose harm to nursing offspring.

Overdosage/Acute Toxicity

Praziquantel has a wide margin of safety. In rats and mice, the oral LD₅₀ is at least 2 g/kg. An oral LD₅₀ could not be determined in dogs, as at doses greater than 200 mg/kg, the drug induced vomiting. Parenteral doses of 50–100 mg/kg in cats caused transient ataxia and depression; injected doses at 200 mg/kg were lethal in cats.

There were 51 exposures to praziquantel reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2001–2006. In these cases 24 were dogs and 27 were cats. No clinical signs were reported.

Drug Interactions

Reportedly in humans, synergistic activity occurs with praziquantel and oxamniquine in the treatment of schistosomiasis. The clinical implications of this synergism in veterinary patients is not clear.

Doses

■ DOGS:

- a) For susceptible cestodes:

IM or SC using the 56.8 mg/mL injectable product:

Body weight: Dose

≤5 lbs: 17 mg (0.3 mL)

6–10 lbs: 28.4 mg (0.5 mL)

11–25 lbs: 56.8 mg (1 mL)

≥25 lbs: 0.2 mL/5 lb body weight; maximum 3 mL

Oral: Using the 34 mg canine tablet:

Body weight: Dose

≤5 lbs: 17 mg (1/2 tab)

6–10 lbs: 34 mg (1 tab)

11–15 lbs: 51 mg (1.5 tabs)

16–30 lbs: 68 mg (2 tabs)

31–45 lbs: 102 mg (3 tabs)

46–60 lbs: 136 mg (4 tabs)

≥60 lbs: 170 mg (5 tabs maximum); (Package insert; *Droncit*®
Injectable and Tablets—Bayer)

- b) For *Echinococcus granulosus*: 10 mg/kg (Sherding 1989)
- c) For *Dipyllobothrium* spp: 7.5 mg/kg PO once (Kirkpatrick, Knochenhauer, and Jacobsen 1987)
- d) For *Spirometra mansonoides* or *Dipyllobothrium erinacei*: 7.5 mg/kg, PO once daily for 2 days (Roberson 1988a)
- e) For treatment of Paragonimiasis (*Paragonimus kellicotti*): 23–25 mg/kg PO q8h for 3 days (Reinemeyer 1995), (Hawkins 2000)

- f) For treatment of liver flukes (*Platynosom* or *Opisthorchiidae* families): 20–40 mg/kg PO once daily for 3–10 days (Taboada 1999)
- g) For *Alaria* spp.: 20 mg/kg PO (Ballweber 2004)
- h) For giardia using *Drontal Plus*®: Use label dose once daily PO for 3 days. (Lappin 2006b)

■ CATS:

- a) For susceptible cestodes:
IM or SC using the 56.8 mg/mL injectable product:
Body weight: Dose
<5 lbs: 11.4 mg (0.2 mL)
5–10 lbs: 22.7 mg (0.4 mL)
≥10 lbs: 34.1 mg (0.6 mL maximum)
Oral: Using the 23 mg feline tab
Body weight: Dose
<4 lbs: 11.5 mg (1/2 tab)
5–11 lbs: 23 mg (1 tab)
>11 lbs: 34.5 mg (1.5 tabs)
(Package insert; *Droncit*® *Injectable* and *Tablets*—Bayer)
- b) For treatment of Paragonimiasis (*Paragonimus kellicotti*): 23–25 mg/kg PO q8h for 3 days (Reinemeyer 1995); (Hawkins 2000)
- c) For treatment of Giardia infections: Give two small dog tablets of *Drontal Plus*® (febantel 113.4 mg; pyrantel 22.7 mg; praziquantel 22.7 mg) once daily PO for 5 days. (Scorza, Radecki et al. 2004)
- d) For *Alaria* spp.: 20 mg/kg PO (Ballweber 2004)
- e) For *Spirometra mansonioides*: 30–35 mg/kg PO. (Bowman 2006b)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Chinchillas: 6–10 mg/kg PO (Hayes 2000)
- b) For tapeworms in mice, rats, hamsters and gerbils: 30 mg/kg, PO once (note the high dosage required) (Burke 1999)
- c) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: For tapeworms: 6–10 mg/kg PO (Adamcak and Otten 2000)

■ SHEEP & GOATS:

- a) For all species of *Moniezia*, *Stilesia*, or *Avitellina*: 10–15 mg/kg (Roberson 1988a)

■ HORSES:

For labeled parasites using the oral gel combination of moxidectin/praziquantel:

- a) Dial in the weight of the animal on the syringe. Administer gel by inserting the syringe applicator into the animal's mouth through the interdental space and depositing the gel in the back of the mouth near the base of the tongue. Once the syringe is removed, the animal's head should be raised to insure proper swallowing of the gel. Horses weighing more than 1250 lb require additional gel from a second syringe. (Label Directions; *Quest*® *Plus*—Fort Dodge)

■ LLAMAS:

For susceptible parasites:

- a) 5 mg/kg, PO (Fowler 1989)

■ BIRDS:

For susceptible parasites (tapeworms):

- a) 1/4 of one 23 mg tablet/kg PO; repeat in 10–14 days. Add to feed or give by gavage. Injectable form is toxic to finches. (Clubb 1986)
- b) For common tapeworms in chickens: 10 mg/kg (Roberson 1988a)

- c) For cestodes and some trematodes: Direct dose: 5–10 mg/kg PO or IM as a single dose -or- 12 mg of crushed tablets baked into a 9"x9"x2" cake. Finches should have their regular food withheld and be pre-exposed to a non-medicated cake. (Marshall 1993)

■ REPTILES:

For cestodes and some trematodes in most species:

- a) 7.5 mg/kg PO once; repeat in 2 weeks PO (Gauvin 1993)

For removal of common tapeworms in snakes:

- a) 3.5–7 mg/kg (Roberson 1988a)

Monitoring

- Clinical efficacy

Client Information

- Fasting is neither required nor recommended before dosing. A single dose is usually effective, but measures should be taken to prevent reinfection, particularly against *D. caninum*.
- Tablets may be crushed or mixed with food.
- Because tapeworms are often digested, worm fragments may not be seen in the feces after using.

Chemistry/Synonyms

A prazinoisoquinoline derivative anthelmintic, praziquantel occurs as a white to practically white, hygroscopic, bitter tasting, crystalline powder, either odorless or having a faint odor. It is very slightly soluble in water and freely soluble in alcohol.

Praziquantel may also be known as: EMBAY-8440, praziquantel, *Biltricide*®, *Bio-Cest*®, *Cercon*®, *Cesol*®, *Cestox*®, *Cisticid*®, *ComboCare*®, *Cysticide*®, *Droncit*®, *Drontal*®, *Ehliten*®, *Equimax*®, *Extiser Q*®, *Mycotricide*®, *Opticide*®, *Quest*® *Plus*, *Praquantel*®, *Prasikon*®, *Prazite*®, *Prozitel*®, *Sincerck*®, *Teniken*®, *Virbantel*®, *Waycital*®, or *Zifartel*® and *Zimecterin Gold Paste*®.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, praziquantel tablets should be stored in tight containers at room temperature. Protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Praziquantel Tablets: 23 mg (feline); 34 mg (canine); *Droncit*® *Tablets* (Bayer); generic; (Rx; OTC). Approved for use in cats and dogs.

Praziquantel Injection: 56.8 mg/mL in 10 mL and 50 mL vials; *Droncit*® *Injection* (Bayer); generic; (Rx). Approved for use in cats and dogs.

Combination Products:

Tablets: Praziquantel 18.2 mg/pyrantel pamoate 72.6 mg (as base); *Drontal*® *Tablets* (Bayer); (OTC). Approved for use in cats and kittens that are 4 weeks of age or older and weigh 1.5 lb. or greater.

Chewable Tablets: Praziquantel 30 mg/pyrantel pamoate 30 mg; & Praziquantel 114 mg/pyrantel pamoate 114 mg chewable tablets; *Virbantel Flavored Chewables*® (Virbac); (OTC). Approved for use in dogs.

Tablets: Praziquantel/pyrantel pamoate plus febantel; *Drontal*® *Plus Tablets* (Bayer); (Rx); small, medium and large dog sizes. Approved for dogs and puppies 3 weeks of age or older and weighing 2 lb. or greater.

Oral Gel: containing 20 mg/mL moxidectin and 125 mg/mL of praziquantel in 11.6 g syringes (sufficient to treat one 1150 lb horse); *Quest*® *Plus* (Fort Dodge); *ComboCare*® *Equine Oral Gel* (Farnam); (OTC). Approved for use in horse or ponies not intended for food purposes.

Oral Paste: containing 1.87% ivermectin and 14.03% of praziquan-
tel in oral syringes (sufficient to treat one 1320 lb horse); *Equimax*®
(Pfizer); (OTC). Approved for use in horse or ponies not intended
for food purposes.

Oral Paste: containing 1.55% ivermectin and 7.75% of praziquan-
tel in oral syringes (sufficient to treat one 1250 lb horse); *Zimecterin*
Gold Paste® (Merial); (OTC). Approved for use in horse or ponies not
intended for food purposes.

HUMAN-LABELED PRODUCTS:

Praziquan-
tel Tablets (Film-coated): 600 mg; *Biltricide*® (Bayer); (Rx)

PRAZOSIN HCL

(pra-zoe-sin) Minipress®

ALPHA-1 ADRENERGIC BLOCKER

Prescriber Highlights

- ▶ Alpha₁-blocker that may be useful for adjunctive treat-
ment of CHF, systemic hypertension, or pulmonary hyper-
tension in dogs
- ▶ Also used to reduce sympathetic tone to treat functional
urethral obstruction in dogs & cats
- ▶ Caution: Chronic renal failure or preexisting hypotensive
conditions
- ▶ Adverse Effects: Potentially hypotension, CNS effects
(lethargy, dizziness, etc.), & GI effects

Uses/Indications

Prazosin is less well studied in dogs than hydralazine, and its capsule dosage form makes it less convenient for dosing. Prazosin, however, appears to have fewer problems with causing tachycardia, and its venous dilation effects may be an advantage over hydralazine when preload reduction is desired. It could be considered for therapy for the adjunctive treatment of CHF, particularly when secondary to mitral or aortic valve insufficiency when hydralazine is ineffective or not tolerated. Prazosin may also be used for the treatment of systemic hypertension or pulmonary hypertension in dogs.

Pharmacology/Actions

Prazosin's effects are a result of its selective, competitive inhibition of alpha₁-adrenergic receptors. It reduces blood pressure and peripheral vascular resistance and, unlike hydralazine, has dilatory effects on both the arterial and venous side.

Prazosin significantly reduces systemic arterial and venous blood pressures, and right atrial pressure; cardiac output is increased in patients with CHF. Moderate reductions in blood pressure, pulmonary vascular resistance, and systemic vascular resistance are seen in these patients. Heart rates can be moderately decreased or unchanged. Unlike hydralazine, prazosin does not seem to increase renin release so diuretic therapy is not mandatory with this agent (but is usually beneficial in CHF).

Pharmacokinetics

The pharmacokinetic parameters for this agent were not located for veterinary species. In humans, prazosin is variably absorbed after oral administration. Peak levels occur in 2–3 hours.

Prazosin is widely distributed throughout the body and is approximately 97% bound to plasma proteins. Prazosin is minimally distributed into milk. It is unknown if it crosses the placenta.

Prazosin is metabolized in the liver and some metabolites have activity. Metabolites and some unchanged drug (5–10%) are primarily eliminated in feces via the bile.

Contraindications/Precautions/Warnings

Prazosin should be used with caution in patients with chronic renal failure or preexisting hypotensive conditions.

Adverse Effects

Syncope secondary to orthostatic hypotension has been reported in people after the first dose of the drug. This effect may persist if the dosage is too high for the patient. CNS effects (lethargy, dizziness, etc.) may occur, but are usually transient in nature. GI effects (nausea, vomiting, diarrhea, constipation, etc.) have been reported. Tachyphylaxis (drug tolerance) has been reported in humans, but dosage adjustment, temporarily withdrawing the drug, &/or adding an aldosterone antagonist (e.g., spironolactone) usually corrects this.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Prazosin is excreted in small amounts in maternal milk and unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity

There were 7 exposures to prazosin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 6 were dogs with 1 showing clinical signs and 1 reported cat case that showed clinical signs. Clinical signs in that dog in decreasing frequency included hyperactivity. Tachycardia was seen in the cat.

Evacuate gastric contents and administer activated charcoal using standard precautionary measures if the ingestion was recent and if cardiovascular status has been stabilized. Treat shock using volume expanders and pressor agents if necessary. Monitor and support renal function.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving prazosin and may be of significance in veterinary patients:

- **BETA-BLOCKING AGENTS** (e.g., **propranolol**): May enhance the postural hypotensive effects seen after the first dose of prazosin
- **CLONIDINE**: May decrease prazosin antihypertensive effects
- **SILDENAFIL** (and other **PDE INHIBITORS**): May increase risk for hypotension
- **VERAPAMIL** or **NIFEDIPINE**: May cause synergistic hypotensive effects when used concomitantly with prazosin

Doses

■ DOGS:

- a) For adjunctive treatment of heart failure: 1 mg PO three times daily for dogs weighing less than 15 kg; 2 mg three times daily PO for dogs weighing more than 15 kg (Kittleson 1985b), (Atkins 2007a)
- b) For hypertension: 1–4 mg (total dose) PO q12–24 hours (Brown and Henik 2000)
- c) For hypertension in a large dog: 1 mg (total dose) PO q8–12h (Ware 2003)
- d) To decrease urethral resistance: 1 mg per 15 kg of body weight PO q8h (Lane 2000)

- e) For functional urethral obstruction: 1 mg/15 kg of body weight PO q8–24h (Lulich 2004)
- f) To decrease urethral resistance: 1 mg per 15 kg of body weight PO q12–24h (Bartges 2006a), (Vernau 2006)

■ CATS:

To decrease urethral resistance:

- a) 0.5 mg (total dose) PO q8h or 0.03 mg/kg IV (Lane 2000)
- b) 0.03 mg/kg IV (Osborne, Kruger et al. 2000)
- c) For functional urethral obstruction: 0.25–0.5 mg/cat (total dose) PO q12–24h (Lulich 2004), (Coates 2004), (Vernau 2006)

Monitoring

- Baseline thoracic radiographs
- Mucous membrane color; CRT
- If possible, arterial blood pressure and venous PO₂

Client Information

- Compliance with directions is necessary to maximize the benefits from this drug. If possible, give medication with food.
- Notify veterinarian if patient's condition deteriorates or if the animal becomes lethargic or depressed.

Chemistry/Synonyms

A quinazoline-derivative postsynaptic α_1 -adrenergic blocker, prazosin HCl occurs as a white to tan powder. It is slightly soluble in water and very slightly soluble in alcohol.

Prazosin may also be known as: CP-12299-1, furazosin hydrochloride, prazosini hydrochloridum; many trade names are available.

Storage/Stability

Prazosin capsules should be stored in well-closed containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Prazosin Capsules: 1 mg, 2 mg & 5 mg (as base); *Minipress*® (Pfizer); generic (Rx)

PREDNISOLONE PREDNISOLONE SODIUM SUCCINATE PREDNISOLONE ACETATE PREDNISONE

(pred-niss-oh-lone); (pred-ni-zone)

For more information refer to the monograph: Glucocorticoids, General Information or to the manufacturer's product information for veterinary labeled products.

Note: Although separate entities, prednisone and prednisolone are often considered bioequivalent; most species rapidly convert prednisone to prednisolone in the liver. **Horses, cats and patients in frank hepatic failure** do not appear to either absorb or convert prednisone to prednisolone efficiently. Use either prednisolone or an alternative glucocorticoid in these patients when possible.

Prescriber Highlights

- **Classic glucocorticoids used for many conditions in many species. Antiinflammatory activity is 4X more potent than hydrocortisone; has some mineralocorticoid activity**
- **Contraindications (relative): Systemic fungal infections**
- **Caution: Active bacterial infections, corneal ulcer, Cushingoid syndrome, diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency**
- **Goal of therapy is to use as much as is required & as little as possible for as short an amount of time as possible**
- **Prednisone poorly absorbed after oral use in horses; prednisone may not be readily converted to prednisolone in cats. Prednisolone is preferred in these two species.**
- **Primary adverse effects are "Cushingoid" in nature with sustained use**
- **Many potential drug & lab interactions**

Uses/Indications

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

In general, in using glucocorticoids, the following principles should be followed:

1. Glucocorticoids can mask disease! Try not to use them until you have a diagnosis.
2. Make a specific diagnosis!
3. Determine course from outset.
4. Determine endpoint before you starting treating.
5. Use the least potent form for the minimal time.
6. Know where glucocorticoids inappropriate. (Behrend 2007)

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

Cardiovascular System: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs' vasoconstrictive properties and increased blood volume that may be produced.

Cells: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes, and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/Autonomic Nervous System: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine System: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T₄) to triiodothyronine (T₃) may be reduced in glucocorticoids and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Hematopoietic System: Glucocorticoids can increase the numbers of circulating platelets, neutrophils, and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells is diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI Tract and Hepatic System: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption increases. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulfophthalein) retention time.

Immune System (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and mono-

cyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Reproductive Tract, Pregnancy, & Lactation: Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas, and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

Renal, Fluid, & Electrolytes: Glucocorticoids can increase potassium and calcium excretion; sodium and chloride reabsorption and extracellular fluid volume. Hypokalemia and/or hypocalcemia occur rarely. Diuresis may occur following glucocorticoid administration.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Pharmacokinetics

Plasma half-life is not meaningful from a therapy standpoint when evaluating systemic corticosteroids. Prednisolone and prednisone are intermediate acting corticosteroids with a biologic "half-life" of 12–36 hours.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia, and those hypersensitive to a particular compound. Sustained-released injectable glucocorticoids are considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting, and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects, however.

Reproductive/Nursing Safety

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Use with caution in nursing dams. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit growth, interfere with endogenous corticosteroid production or cause other unwanted effects in nursing offspring. In humans, however, several studies suggest that amounts excreted in breast milk are negligible when prednisone or prednisolone doses in the mother are less than or equal to 20 mg/day or methylprednisolone doses are less than or equal to 8 mg/day. Larger doses for short periods may not harm the infant.

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral prednisolone/prednisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
- **DIGOXIN:** Secondary to hypokalemia, increased risk for arrhythmias
- **DIURETICS, POTASSIUM-DEPLETING (furosemide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May increase metabolism of glucocorticoids
- **ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE:** May decrease metabolism of glucocorticoids
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of other ulcerogenic drugs with glucocorticoids may increase risk
- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids
- **PHENYTOIN:** May increase the metabolism of glucocorticoids
- **RIFAMPIN:** May increase the metabolism of glucocorticoids
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease serum **potassium**.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃** & **T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I¹³¹ by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- False-negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

Doses

■ DOGS:

For adjunctive treatment of neoplasms:

For more information on using prednisone or prednisolone as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numer-

ous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

- a) Brain tumors (palliative therapy): Prednisone 0.5–1 mg/kg PO once a day to every other day. (Fenner 1988); Prednisone 0.5–1 mg/kg PO twice daily for several days, then decrease dosage over the next week or month, dependent on patient's needs (LeCouteur and Turrel 1986)
- b) For adjunctive therapy in canine lymphomas:
COAP (cyclophosphamide, vincristine, cytosine arabinoside, prednisone) protocol: Prednisone: 50 mg/m² PO every day for one week, then 25 mg/m² every other day.
COP (no cytosine arabinoside) protocol: Prednisone 25 mg/m² PO every other day.
CHOP (doxorubicin instead of cytosine arabinoside): Prednisone 25 mg/m² PO every other day (Couto 1986)
- c) For adjunctive therapy for multiple myeloma: Prednisone 0.5 mg/kg PO once daily. Used with melphalan: 0.1 mg/kg PO once daily for 10 days, then 0.05 mg/kg PO once daily or with cyclophosphamide: 1 mg/kg PO once daily (if resistance develops to melphalan). (Jenkins 1985)
- d) For macroglobulinemia: Prednisone 0.5 mg/kg PO once daily. Used with chlorambucil: 0.2 mg/kg PO once daily for 10 days, then 0.1 mg/kg PO once daily or with cyclophosphamide: 1 mg/kg PO once daily (if resistance develops to chlorambucil) (Jenkins 1985)

For adjunctive treatment of respiratory disorders:

- a) Chronic bronchitis: Prednisone 0.5–1 mg/kg PO once a day to every other day (Bauer 1988)
- b) Allergic bronchitis: Prednisolone sodium succinate: 2–4 mg/kg IV or IM (do not give via rapid IV infusion). In chronically symptomatic patient: prednisone 0.5–1.5 mg/kg/day PO (Bauer 1988)
- c) For adjunctive therapy of collapsing trachea:
Initially, prednisolone 0.25–0.5 mg/kg PO twice daily for 7–10 days (Prueter 1988b)
Prednisone: 0.5 mg/kg, PO once or twice a day. Discontinue if no improvement in one week. Corticosteroids must be used cautiously in this condition and rarely make a difference in the long-term outcome of therapy. (Fingland 1989)
- d) For allergic (eosinophilic) bronchitis or pneumonitis: Prednisone 1–2 mg/kg/day divided two to three times a day. Every 7–10 days decrease total steroid dose by 1/4–1/2 as long as signs are controlled. After 3–4 weeks, every other day or every third day therapy may be attempted. (Noone 1986)
- e) For adjunctive therapy of parasitic pulmonary hypersensitivities: To suppress inflammation prior to parasite elimination: Prednisolone 1–2 mg/kg PO divided into 2–3 doses (Noone 1986)

For adjunctive therapy in liver disorders: **Note:** Because prednisone requires conversion to the active compound prednisolone by the liver, some clinicians believe that only prednisolone should be used in patients with liver disease.

- a) For cholangitis: Prednisolone 1–2 mg/kg PO once daily for at least 1 month. Then give every other day for another 2–3 months and consider discontinuing and monitoring for relapse. (Cornelius and Bjorling 1988)

- b) For chronic lymphocytic-plasmacytic or autoimmune hepatitis: 2.2 mg/kg, PO once daily for several weeks and then tapered to 1.1 mg/kg every other day. If dogs cannot tolerate or fail prednisone may add azathioprine. (Twedt 1999)
- c) Copper-induced hepatopathy: Prednisolone 0.5–1 mg/kg PO divided twice daily (used during acute stages). Used with chelation therapy and dietary copper restriction. (Cornelius and Bjorling 1988)

For adjunctive therapy of disorders of the gastrointestinal tract:

- a) For eosinophilic colitis: Prednisolone 1–2 mg/kg PO for 7–10 days. Gradually decrease dose over following 3–4 weeks to a minimal dosage that will control clinical signs. Some cases will require additional alternate-day therapy for an additional 3–4 weeks. (DeNovo 1988)
- b) For eosinophilic enteritis: Prednisolone 1–3 mg/kg PO once daily; gradually taper to every other day dosing for maintenance. May use injectable forms if dog is vomiting or malabsorption is severe. Therapy may be necessary for weeks to months. Do not use until intestinal biopsy sites are healed (usually 7–10 days). (Chiapella 1988);
Prednisone 0.5 mg/kg, PO once daily initially; reduce gradually to alternate day therapy (Hall and Twedt 1989);
Prednisolone: 0.5–1 mg/kg twice daily for 5–7 days, then decrease to 0.5 mg/kg/day for 5–7 days. Taper dose to alternate-day therapy as condition dictates. Additional therapy for 3–4 weeks is often necessary. Relapses can occur. (DeNovo 1986)
- c) For eosinophilic colitis when dietary and parasitic infestations have been eliminated or when other appropriate therapy has been unsuccessful: Prednisolone 0.5–1 mg/kg two times a day; taper dose gradually over a 3–4 week period to the lowest effective dose. (Chiapella 1986)
- d) For plasmacytic/lymphocytic enteritis: Prednisolone 2.2 mg/kg PO divided twice daily for 5–10 days, then 1.1 mg/kg/day for 5–10 days. Then taper by reducing steroid dosage by 1/2 every 10–14 days until alternate-day dosage is attained or symptoms recur. (Chiapella 1988)
- e) For adjunctive therapy of chronic superficial gastritis (if predominance of lymphocyte and plasma cell infiltration seen on biopsy): Prednisone 0.5–1 mg/kg PO divided twice daily initially and reduced over a 3 month period to lowest, alternate-day effective dosage (Hall and Twedt 1989)
- f) Ulcerative colitis: May cause some patients' condition to worsen. Use only after an unsuccessful trial of sulfasalazine. Use with caution. Prednisolone 1–2 mg/kg/day PO for 5–7 days; then 0.5 mg/kg/day for an additional 5–7 days; then 0.25–0.5 mg/kg PO every other day for 10–14 days. Continue sulfasalazine during steroid therapy. If significant improvement is not seen within the first 7 days of therapy, steroids are tapered and discontinued more rapidly. (DeNovo 1988)
- g) For food allergy or intolerance: Prednisone 0.5 mg/kg PO once daily; taper dose weekly if clinical response dictates. Discontinue when clinical remission ensues. (Chiapella 1988)
- h) For adjunctive therapy of endotoxemia secondary to GDV: Prednisolone sodium succinate: 11 mg/kg IV (Bellah 1988); Prednisolone sodium succinate 10 mg/kg (Orton 1986)
- i) For eosinophilic gastritis: Prednisone 0.5 mg/kg once daily for 1–2 weeks; gradually taper to 0.12 mg/kg, PO every other day (Twedt and Magne 1986)

- j) For adjunctive therapy of intestinal lymphangiectasia: prednisolone 2–3 mg/kg/day. Once remission is attained, may taper to a maintenance dosage. Not all cases respond. (Sherding 1986)
- k) For adjunctive therapy of refractory wheat-sensitive enteropathy in Irish Setters: Prednisolone 0.5 mg/kg every 12 hours for one month. Then begin a reducing dosage schedule. (Batt 1986)
- l) For dogs who respond poorly to conventional therapy (enzyme replacement, dietary modification, vitamin supplementation, and antibiotics) for exocrine pancreatic insufficiency: Prednisolone 1–2 mg/kg every 12 hours for 7–14 days. May reduce over 4–6 weeks as patient tolerates. (Williams 1989)

For adrenal diseases:

- a) For adjunctive treatment of hypoadrenal crisis: Prednisolone sodium succinate: 4–20 mg/kg IV over 2–4 minutes, preferably after ACTH response test is completed. IV normal saline is usually sufficient therapy during the first hour until ACTH response test is completed. Prednisolone sodium succinate may be repeated in 2–6 hours or dexamethasone may be added to IV infusion at 0.05–0.2 mg/kg q12h. Prednisolone sodium succinate possesses some mineralocorticoid activity, while dexamethasone does not. (Feldman 1989)
- b) For glucocorticoid supplementation in chronic or subacute adrenal insufficiency: Prednisolone 0.2–0.4 mg/kg PO per day (Feldman, Schrader, and Twedt 1988)
- c) For glucocorticoid supplementation if azotemia or other symptoms of glucocorticoid deficiency result: Prednisolone 0.1–0.3 mg/kg PO per day (Schrader 1986)
- d) For glucocorticoid “coverage” before and after adrenal tumor removal: Prednisolone sodium succinate 1–2 mg/kg IV either at 1 hour prior to surgery or at the time of anesthesia induction. May also add to IV fluids and administer IV during the procedure. Repeat dosage at end of procedure; may give IM or IV. Glucocorticoid supplementation must be maintained using an oral product (initially prednisolone 0.5 mg/kg twice daily, cortisone acetate 2.5 mg/kg twice daily, or dexamethasone 0.1 mg/kg once daily). Slowly taper to maintenance levels (prednisolone 0.2 mg/kg once a day, or cortisone acetate 0.5 mg/kg two times a day) over 7–10 days. Should complications develop during the taper, reinstitute doses at 5 times the maintenance dose. Most dogs can stop exogenous steroid therapy in about 2 months (based on an ACTH stimulation test). (Peterson 1986)
- e) For glucocorticoid “coverage” in animals who have iatrogenic secondary adrenocortical insufficiency and/or HPA suppression: Animals exhibiting mild to moderate signs of glucocorticoid deficiency: Prednisolone 0.2 mg/kg PO every other day. For animals with HPA suppression undergoing a “stress” factor: Prednisolone sodium succinate 1–2 mg/kg just before and after stressful events (e.g., major surgery). Continue with lower dosages until at least 3rd post-operative day. Access to a water-soluble form of glucocorticoid should be available should animal “collapse.” (Kemppainen 1986)
- f) For symptoms of glucocorticoid deficiency (anorexia, diarrhea, listlessness) or in well-controlled patients receiving mitotane (*Lysodren*®) therapy for hyperadrenocorticism undergoing a “stress”: Prednisone 2.2 mg/kg PO for 2 days, then 1 mg/kg for 2 days, then 0.5 mg/kg for 3 days, then 0.5 mg/kg every other day for one week, then stop. Reintroduce therapy or readjust dosage should symptoms recur. (Feldman 1989)

For adjunctive or alternative medical management of hyperinsulinism:

- a) Prednisone 0.5 mg/kg PO divided twice daily initially; increase dose as required, to maintain euglycemia (Kay, Kruth, and Twedt 1988)
- b) Prednisolone 1 mg/kg divided twice-daily PO, then decrease to a minimally effective dosage (Lothrop 1989)

For adjunctive therapy of toxicoses:

- a) For cholecalciferol toxicity: Prednisone 1–2 mg/kg PO two to three times daily (Grauer and Hjelle 1988a)
- b) For adjunctive therapy of endotoxemia secondary to garbage or carrion ingestion: Prednisolone sodium succinate 5–7 mg/kg IV every 4 hours (Coppock and Mostrom 1986)

For adjunctive therapy of reproductive disorders:

- a) In bitches prone to relapse after initial therapy of eclampsia (puerperal tetany): Prednisone 0.25 mg/kg PO once daily during lactation and slowly withdrawn (Barton and Wolf 1988);

Prednisolone 0.5 mg/kg twice daily (Russo and Lees 1986)

For adjunctive therapy of heartworm disease (considered by some clinicians to be contraindicated during treatment for routine post-adulticide therapy as pulmonary thromboses may be promoted):

- a) Prednisolone 1–2 mg/kg PO divided two times a day. Reduce dosage over next 7–14 days. (Knight 1988)
- b) Dogs with severe cough, hemoptysis, or extensive parenchymal involvement: Prior to adulticide therapy, prednisolone 1–2 mg/kg PO divided twice daily and tapered over a 10–14 day period (Noone 1986)
- c) For pneumonitis associated with occult heartworm disease: Prednisone 1–2 mg/kg daily for 3–5 days. After steroids are stopped, give adulticide therapy immediately. (Calvert and Rawlings 1986)

For CNS disorders:

- a) For granulomatous meningoencephalitis: Prednisone: 1–2 mg/kg PO daily for the life of the patient. (Fenner 1988); prednisone 2–3 mg/kg PO divided twice daily for 2 weeks, then slowly reduce dosage over several weeks; long-term therapy is recommended. (Schunk 1988a)
- b) For reticulosis: Prednisone: 1–2 mg/kg/day PO until symptoms begin to subside, then begin taper. Continue low-dose once a day or every other day therapy indefinitely. (Fenner 1988);

Prednisone 2–3 mg/kg PO divided twice daily for 2 weeks, then slowly reduce dosage over several weeks; long-term therapy is recommended. (Schunk 1988a)

Prednisolone: 2 mg/kg PO for 1 week, then 1 mg/kg/day for 1 week, then 0.5 mg/kg/day for 1 week, then 0.5 mg/kg every other day for 1 week, then 0.25 mg/kg every other day for 1 week, then 0.25 mg/kg every 3rd day (Riis 1986)

- c) For adjunctive therapy of hydrocephalus: For long-term management, prednisone 0.5 mg/kg, PO every other day may be tried. (Fenner 1988)

Prednisone 0.25–0.5 mg/kg PO two times a day; continue if improvement is noted within one week and decrease dosage at weekly intervals to 0.1 mg/kg PO every other day eventually. Maintain dose for at least one month. (Shores 1989)

- d) For adjunctive medical therapy of intervertebral disk disease (IVD):

Cervical IVD: Prednisolone 0.5 mg/kg PO twice daily for 3 days, then 0.5 mg/kg once daily for 3–5 days;

Thoracolumbar IVD: Prednisolone 0.5–1 mg/kg SC or PO twice daily for 2–3 days, then taper dosage over next 3–5 days (Schunk 1988a)

e) For adjunctive therapy of spondylopathy:

Cervical: For dogs with slowly progressive course and still ambulatory, use prednisone: 1–2 mg/kg PO divided twice daily initially. Gradually reduce dose every 2 weeks until reach 0.5 mg/kg PO every other day.

Lumbosacral: Prednisone: 1 mg/kg PO divided twice daily initially. Gradually reduce dose to 0.5 mg/kg, PO every other day (Schunk 1988a)

f) For adjunctive therapy of White Dog Shaker Syndrome: Prednisone 0.25 mg/kg PO twice daily for 10 days, then once a day for 10 days, then every other day for 10 days (Fenner 1988)

g) For adjunctive therapy of generalized tremor syndrome: Prednisolone 3 mg/kg each AM for 5 days, then decreased to alternate mornings for 5 days, then begin a phased withdrawal of drug. May require long-term low-dose alternate day therapy. (Farrow 1986)

h) For nonbacterial suppurative meningitis: After cultures are confirmed negative, prednisone 2 mg/kg for 10 days, then taper slowly over 1 month (Fenner 1986b)

i) For adjunctive therapy of dogs diagnosed with canine wobbler syndrome with signs of mild to moderate paraparesis, tetraparesis, or ataxia: Prednisolone 1–2 mg/kg twice daily initially, decrease gradually over a 5 day period to 0.5–1 mg/kg on alternate days (Trotter 1986)

For hematologic disorders:

a) For autoimmune hemolytic anemia: Prednisolone 1–4 mg/kg PO daily divided two times a day. Add immunosuppressive agent (e.g., cyclophosphamide, azathioprine) if PCV does not stabilize within 48–72 hours. May take several months to wean off drugs. (Maggio-Price 1988)

b) For adjunctive therapy of pure red blood cell aplasia (PRCA): Prednisolone 2 mg/kg divided two times a day. If no increases in reticulocyte count in 2-weeks, increase to 4 mg/kg, two times a day. If reticulocyte counts remain low after 4–6 weeks add cyclophosphamide (30–50 mg/m² on 4 consecutive days each week). Continue prednisolone. Discontinue cyclophosphamide if neutropenia or thrombocytopenia occurs. If reticulocyte count increases, cyclophosphamide may be discontinued and prednisolone slowly tapered to alternate day therapy. (Weiss 1986)

c) For immune-mediated thrombocytopenia: Prednisolone 1–3 mg/kg PO divided two to three times a day. Do not give IM injections. If platelet-count increases, prednisolone dose may be tapered by 50% every 1–2 weeks. Reduction in dose should be done slowly over several months. (Johnessee and Hurvitz 1983)

For dermatologic or other immune-mediated disorders:

a) For adjunctive therapy of urticaria and angioedema: Prednisone 2 mg/kg PO or IM twice daily (Giger and Werner 1988)

b) For canine atopy: Prednisolone 0.5 mg/kg PO twice daily initially for 5–10 days, then taper to the minimum effective alternate-day dosage (Giger and Werner 1988)

c) For adjunctive flea allergy dermatitis: Prednisolone 1 mg/kg PO once a day for 1 week, then every other day at a minimally effective dose (Giger and Werner 1988)

d) As an immunosuppressant for auto-immune skin diseases: Prednisolone 2.2 mg/kg twice daily until remission; then taper to lowest effective every other day dosage (Giger and Werner 1988)

e) For type II (cytotoxic) hypersensitivity: Prednisolone 2 mg/kg two times a day. Once in remission, dosage may be reduced to a maintenance level. Other immunosuppressants may be required (Wilcke 1986)

f) For adjunctive therapy of urticaria, shock, and/or respiratory arrest secondary to contrast media hypersensitivity: Prednisolone sodium succinate 10 mg/kg IV (Walter, Feeney, and Johnston 1986)

g) For adjunctive therapy of surface pyodermas: Prednisolone 1 mg/kg/day for 5–7 days (Ihrke 1986)

h) For eosinophilic ulcer: Prednisolone 2–4.4 mg/kg PO once a day; for chronic cases use prednisolone 0.5–1 mg/kg PO every other day (DeNovo 1988)

Miscellaneous Indications:

a) For boxer cardiomyopathy: In patients not responding to antiarrhythmic agents: Prednisolone 1 mg/kg twice daily for 10 days (Ware and Bonagura 1986)

b) As an appetite stimulant: Prednisolone 0.25–0.5 mg/kg PO every day, every other day, or intermittently as needed. (Macy and Ralston 1989)

c) For adjunctive therapy of posterior uveitis: Prednisolone 2.2 mg/kg once daily; gradually reduce dose as inflammation is controlled (Swanson 1989)

d) For chronic, proliferative, pyogranulomatous laryngitis: Prednisolone 1 mg/kg twice daily PO; decrease dosage weekly (Prueter 1988a)

e) For adjunctive or alternate therapy for hypercalcemia: Prednisolone 1–1.5 mg/kg PO q12h. Has a delayed onset of action and a 4–8 day duration of response. (Kruger, Osborne, and Polzin 1986)

f) As an antiinflammatory in the adjunctive treatment of otitis interna: Prednisone 0.25 mg/kg/day for first 5–7 days of treatment (Neer 1988)

g) For adjunctive therapy of myasthenia gravis: Prednisone 0.5 mg/kg/day PO. Increase in 0.5 mg/kg/day increments every 2–4 days until total dose of 2 mg/kg/day is attained. After remission is achieved, gradually shift to every other day therapy. Should patient worsen during period when prednisone dose is increased, reduce dose and increase the intervals between dosage increases. May take several weeks to see a positive response. After signs are controlled, reduce dosage every 4 weeks until maintenance dose is determined. Cytotoxic drugs may be indicated should symptoms not be controlled or if dosage cannot be reduced. (LeCouteur 1988)

■ CATS:

Note: Use prednisolone in place of prednisone in this species whenever possible. Cats may not absorb or convert prednisone as well as dogs.

As an immunosuppressive agent:

a) Prednisolone: Initially 2–4 mg/kg daily in divided doses. Taper to alternate day, low-dose therapy as rapidly as patient allows. (Gorman and Werner 1989)

For adjunctive treatment of respiratory disorders:

a) Allergic bronchitis: Prednisolone sodium succinate: 1–3 mg/kg IV or IM (do not give via rapid IV infusion) (Bauer 1988)

- b) For adjunctive therapy of feline asthma: Predniso(lo)ne: 1–2 mg/kg/day (Papich 1986);
- c) For adjunctive emergency therapy: Prednisolone sodium succinate 50–100 mg IV. For non-emergency cases: Prednisone 5 mg PO three times daily initially, then rapidly decrease to alternate day use (or discontinue) (Noone 1986)

For adjunctive therapy of disorders of the gastrointestinal tract:

- a) For plasmacytic/lymphocytic enteritis: Prednisolone 2.2 mg/kg PO divided twice daily for 5–10 days, then 1.1 mg/kg/day for 5–10 days, then taper by reducing steroid dosage by 1/2 every 10–14 days until alternate-day dosage is attained or symptoms recur (Chiapella 1988)
- b) For small intestinal inflammatory bowel disease: Prednisone 1–2 mg/kg/day divided into 2 doses. Mild to moderate cases generally will respond to the lower dosage. If severe, use the higher dose and treat for 2–4 weeks or until symptoms resolve. In severe cases characterized by anorexia, weight loss, and chronic diarrhea, use an initial dose of 4 mg/kg/day for 2 weeks. If response is good, decrease dose by 1/2 after 2 weeks and again by 1/2 at 4 weeks. Eventually, alternate day therapy can be attained and should be maintained for 3 months. Some cats may have drugs discontinued in 3 months or long-term alternate day (or every 3rd day dosing) may be required. (Tams 1986)

For adjunctive therapy of feline plasma cell gingivitis-pharyngitis:

- a) Prednisolone 1–2 mg/kg PO once daily (DeNovo, Potter, and Woolfson 1988)

For adjunctive therapy of feline heartworm disease:

- a) For crisis due to embolization; Prednisolone 4.4 mg/kg three times daily with careful IV fluid therapy (Dillon 1986)

For dermatologic conditions:

- a) For adjunctive treatment of flea allergy: Predniso(lo)ne 1–2 mg/kg PO q12h for 5 days, then gradually taper to alternate-day therapy (usually 1–2 mg/kg every other evening) (Kwochka 1986)
- b) For idiopathic feline miliary dermatoses: Predniso(lo)ne 1–2 mg/kg PO q12h for 5–7 days, then reduce gradually to alternate-day therapy at 1–2 mg/kg. Rarely is effective for long-term use. (Kwochka 1986)
- c) For linear granulomas: Prednisolone 0.5 mg/kg twice daily initially, with taper (Thoday 1986)
- d) For eosinophilic ulcer: Prednisolone 2–4.4 mg/kg PO once a day; for chronic cases use prednisolone 0.5–1 mg/kg PO every other day (DeNovo, Potter, and Woolfson 1988)

As adjunctive therapy for feline neoplasias (lymphosarcoma, acute lymphoid leukemia, mast cell neoplasms):

- a) 20–50 mg/m² q24–48h PO, SC or IV (Couto 1989). See also the protocols noted in the canine dosage section.

■ CATTLE:

For adjunctive therapy of cerebral edema secondary to polioencephalomalacia:

- a) Prednisolone 1–4 mg/kg intravenously (Dill 1986)

For adjunctive therapy of aseptic laminitis:

- a) Prednisolone (assuming sodium succinate salt) 100–200 mg IM or IV; continue therapy for 2–3 days (Berg 1986)

For glucocorticoid activity:

- a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM (Howard 1986)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: Rarely indicated. Use with caution; concurrent gastroprotectant is recommended. For spinal trauma: 0.25–0.5 mg/kg PO q12h for 3 days, then once daily for 3 days, then once every other day for 3 doses.

As an antiinflammatory: 0.5–2 mg/kg PO (Ivey and Morrissey 2000)

- b) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.5–2.2 mg/kg IM or SC (Adamcak and Otten 2000)

■ FERRETS:

As an antiinflammatory or for insulinoma (postsurgical or non-surgical cases):

- a) 0.5–2 mg/kg PO or IM (frequency not specified) (Williams 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

Note: Prednisone does not appear to be absorbed very well after oral dosing; use prednisolone or another oral steroid.

For adjunctive therapy of COPD:

- a) Prednisolone: Initially, 600–800 mg IM or PO in a 450 kg horse. May be possible to decrease dose and go to alternate day dosing. Doses as low as 200 mg every other day may be effective. (Beech 1987a)

For glucocorticoid effects:

- a) Prednisolone sodium succinate: 0.25–1 mg/kg IV, Predniso(lo)ne tablets 0.25–1 mg/kg PO; Prednisolone acetate: 0.25–1 mg/kg IM or 10–25 mg subconjunctivally (Robinson 1987)

■ LLAMAS:

For steroid-responsive pruritic dermatoses secondary to allergic origins:

- a) Prednisone: 0.5–1 mg/kg PO initially, gradually reduce dosage to lowest effective dose given every other day (Rosychuk 1989)

■ SWINE:

For glucocorticoid activity:

- a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM (Howard 1986)

■ BIRDS:

As an antiinflammatory:

- a) Prednisolone: 0.2 mg/30 gram body weight, or dissolve one 5 mg tablet in 2.5 mL of water and administer 2 drops orally. Give twice daily. Decrease dosage schedule if using long-term. (Clubb 1986)

For treatment of shock:

- a) Prednisolone sodium succinate (10 mg/mL): 0.1–0.2 mL/100 grams body weight. Repeat every 15 minutes to effect. In large birds, dosage may be decreased by 1/2. (Clubb 1986)

■ REPTILES:

For shock in most species using prednisolone sodium succinate:

- a) 5–10 mg/kg IV as needed (Gauvin 1993)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin

- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

Chemistry/Synonyms

Prednisolone and prednisone are synthetic glucocorticoids. Prednisolone and prednisolone acetate occur as odorless, white to practically white, crystalline powders. Prednisolone is very slightly soluble in water and slightly soluble in alcohol. The acetate ester is practically insoluble in water and slightly soluble in alcohol. The sodium succinate ester is highly water-soluble.

Prednisone occurs as an odorless, white to practically white, crystalline powder. Prednisone is very slightly soluble in water and slightly soluble in alcohol.

Prednisolone is also known as deltahydrocortisone or metacortandralone.

Prednisone may also be known as: delta(1)-cortisone, 1,2-dehydrocortisone, deltacortisone, deltadehydrocortisone, metacortandracin, NSC-10023, prednisonum; many trade names are available.

Storage/Stability/Compatibility

Prednisolone and prednisone tablets should be stored in well-closed containers. All prednisone and prednisolone products should be stored at temperatures less than 40°, and preferably between 15–30°C; avoid freezing liquid products. Do not autoclave. Oral liquid preparations of prednisone should be stored in tight containers. Do not refrigerate prednisolone syrup.

Prednisolone sodium succinate should be stored at room temperature and protected from light (store in carton). After reconstitution, the product is recommended for immediate use and not to be stored for later use.

Little data appears to be available regarding the compatibility of prednisolone sodium succinate injection (*Solu-Delta Cortef*®—Upjohn) with other products. A related compound, prednisolone sodium phosphate is reportedly physically **compatible** with the following drugs/solutions: ascorbic acid injection, cephalothin sodium, cytarabine, erythromycin lactobionate, fluorouracil, heparin sodium, methicillin sodium, penicillin G potassium/sodium, tetracycline HCl, and vitamin B-Complex with C. It is reportedly physically **incompatible** with: calcium gluconate/gluceptate, dimenhydrinate, metamamol bitartrate, methotrexate sodium, prochlorperazine edisylate, polymyxin B sulfate, promazine HCl, and promethazine. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

A zero tolerance of residues in milk for these compounds have been established for dairy cattle. All these agents require a prescription (Rx). Known approved-veterinary products for systemic use are indicated below.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

Prednisolone Tablets: 5 mg, 20 mg: *Prednis-Tab*® (Vedco, Phoenix Pharmaceutical, Vet-A-Mix); generic; (Rx). Approved for use in dogs.

Prednisolone, Tetracycline, Novobiocin Tablets: each tablet contains 60 mg tetracycline, 60 mg novobiocin, 1.5 mg prednisolone. *Delta Albaplex*®; each tablet contains 180 mg tetracycline, 180 mg novobiocin, and 4.5 mg prednisolone *Delta Albaplex*® 3X (Pfizer); (Rx). Approved for use in dogs.

Prednisolone & Trimeprazine Tartrate Tablets: each tablet contains trimeprazine 5 mg and prednisolone 2 mg. *Temaril-P*® (Pfizer Animal Health); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

Prednisolone Tablets: 5 mg generic; (Rx)

Prednisolone Sodium Phosphate Orally Disintegrating Tablets: 10 mg, 15 mg & 30 mg (as base); *Orapred ODT*® (Alliant Pharmaceuticals); (Rx)

Prednisolone Syrup/Oral Liquid or Solution: 1 mg/mL, 3 mg/mL; in 120 mL, 237 mL, 240 mL and 480 mL; *Prelone*® (Aero); *Pediapred*® (UCB Pharma); *Orapred*® (BioMarin); generic; (Rx)

Prednisone Tablets: 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg & 50 mg; *Meti-corten*® (Schering); *Orasone*® (Solvay); *Panasol-S*® (Seatracer); *Deltasone*® (Upjohn); *Prednicen-M*® (Central); *Sterapred*® and *Sterapred DS*® (Merz); generic; (Rx)

Prednisone Oral Solution/Syrup: 1 mg/mL in 120 mL, 240 mL, 500 mL and UD 5 mL; 5 mg/mL in 30 mL; *Prednisone* and *Prednisone Intenol*® Concentrate (Roxane); *Liquid Pred*® (Muro); (Rx)

Ophthalmic solutions/suspensions are available.

PRIMAQUINE PHOSPHATE

(*prim-ah-kwin*)

ANTIPROTOZOAL

Prescriber Highlights

- Antiprotozoal agent considered the drug of choice for treating *Babesia felis* in cats; does not apparently “cure” the infection; repeated courses of therapy may be necessary
- May also be useful in treating *Hepatozoon canis* in dogs or *Plasmodium* spp. in birds
- Most common adverse effect in cats is nausea; giving with food may help
- Very narrow therapeutic index (safety margin); must be careful in determining dosages
- Monitoring CBC mandatory

Uses/Indications

Primaquine is considered the drug of choice for treating *Babesia felis* in cats. Primaquine does not apparently “cure” the infection; repeated courses of therapy may be necessary. It may be useful in treating *Hepatozoon canis* in dogs or *Plasmodium* spp. in birds. In humans, primaquine is used for treatment and prophylaxis for malaria and treating *Pneumocystis pneumonia*.

Pharmacology/Actions

Primaquine's antiprotozoal mechanism of action is not well understood, but it may be related to it binding and altering protozoal DNA.

Pharmacokinetics

No pharmacokinetic information was located for small animals. In humans, primaquine rapidly absorbed with high (96%) systemic bioavailability. It is extensively distributed and rapidly metabolized in the liver to carboxyprimaquine. It is not known if this metabolite has any antiprotozoal activity. Elimination half-life is around 6 hours for primaquine; 24 hours for carboxyprimaquine.

Contraindications/Precautions/Warnings

Primaquine is contraindicated in patients with known hypersensitivity to it. In humans, it is contraindicated in patients receiving other bone marrow suppressant medications or patients susceptible to granulocytopenia (e.g., lupus, rheumatoid arthritis). The CDC states the drug is contraindicated in individuals with G-6-PD deficiency, and during pregnancy or lactation (unless nursing infant determined not to be G-6-PD deficient).

Adverse Effects

Vomiting is the most common adverse effect in cats associated with primaquine; dosing with food may help alleviate this problem. Other concerns include myelosuppression, methemoglobinemia and hemolysis. Safety margin is particularly narrow with this drug in cats (see Overdoses).

Reproductive/Nursing Safety

The CDC recommends using chloroquine or mefloquine for humans during pregnancy and to defer using primaquine until after delivery primarily because primaquine can cause hemolytic anemia in G-6-PD deficient fetuses. It is also contraindicated during lactation in nursing infants unless they are determined not to be G-6-PD deficient. While significance for veterinary patients is not clear, primaquine should be avoided during pregnancy and lactation.

Overdosage/Acute Toxicity

In cats, it has been reported that dosages greater than 1 mg/kg can be lethal. Overdoses should initially be handled aggressively using standardized protocols for removal of drug from the gut and to prevent absorption. Because of the potential seriousness of overdoses, it is recommended to contact an animal poison control center for guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving primaquine and may be of significance in veterinary patients:

- **QUINACRINE:** May potentiate the toxicity of one another; use of primaquine within 3 months of quinacrine is not recommended
- **BONE MARROW DEPRESSANT DRUGS** (e.g., amphotericin B, azathioprine, chloramphenicol, many antineoplastic drugs) or **HEMOLYTIC DRUGS** (e.g., acetohydroxamic acid, sulfonyleureas, quinidine, sulfonamides): Use with primaquine may cause increased risk for toxicity

Laboratory Considerations

No specific concerns noted

Doses

■ CATS:

Note: Dosing for humans for primaquine is usually described in terms of primaquine base, but dosages for cats may not directly specify whether primaquine is being dosed as the phosphate or as the base. Because primaquine has an extremely narrow therapeutic index in cats, this is problematic as a 26.3 mg primaquine phosphate tablet contains only 15 mg of primaquine base. Additionally, commercially available tablets are usually too concentrated to be accurately dosed in domestic cats; a specialized compounding pharmacy should be employed to prepare a suitable dosage form. Be clear as to the amount of primaquine base or phosphate wanted per dose.

- a) For *Babesia felis*: 0.5 mg (as base)/kg PO once daily for 1–3 days. (Greene, Hartmann et al. 2006)
- b) For *Babesia felis*: 1 mg (total dose per cat) primaquine phosphate PO every 36 hours for 4 treatments, then 1 mg (total dose) per cat every 7 days for 4 treatments. The drug does not sterilize the infection. (Lobetti 2005)
- c) For *Babesia felis*: Primaquine phosphate 1 mg/kg IM one time. (Birkenheuer 2005) **Note:** IM dosage form must be compounded.

Monitoring

- CBC; weekly while treating
- Improved clinical signs (increased appetite and body weight, improvement in anemia)

Client Information

- This drug has a very low safety margin when used in cats; exact adherence with the prescribed dosage is very important; do not double-up the next dose if a dose was previously missed
- Give dose with food to reduce chance for GI problems (vomiting)

Chemistry/Synonyms

Primaquine phosphate is an 8-amino-quinoline compound that occurs as an orange-red, odorless, bitter-tasting, crystalline powder. It is soluble (1 gram in 15 mL) in water and practically insoluble in alcohol. 1 mg of primaquine phosphate contains 0.57 mg of primaquine base.

Primaquine may also be known as primachina, primachinum, primaquina or SN 13272.

Storage/Stability

Primaquine phosphate tablets should be stored in a tight, light resistant container below 40°C, preferably between 15–30°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Primaquine Phosphate Tablets: 26.3 mg (equivalent to 15 mg primaquine base); generic; (Rx)

PRIMIDONE

(*pri*-mi-done) Mysoline®, Neurosyn®

ANTICONVULSANT

Prescriber Highlights

- ▶ Phenobarbital precursor that may be useful for treating seizures in dogs; most recommend using phenobarbital instead
- ▶ Contraindications: Severe liver disease or patients with demonstrated previous hypersensitivity. Large Doses Contraindicated: Nephritis or severe respiratory dysfunction
- ▶ Extreme Caution: Cats
- ▶ Caution: Hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease
- ▶ Adverse Effects: DOGS: anxiety & agitation when initiating therapy, increases in liver enzymes, hepatic lipidosis, hepatocellular hypertrophy/necrosis, extramedullary hematopoiesis, depression, polydipsia, polyuria, & polyphagia, anorexia, tachycardia, dermatitis, episodic hyperventilation, urolith formation; rarely megaloblastic anemia
- ▶ Possibly more hepatotoxic than phenobarbital to dogs
- ▶ Most of the anticonvulsant activity comes from the phenobarbital metabolite of primidone
- ▶ Drug Interactions, lab interactions

Uses/Indications

Primidone is indicated for seizure control (idiopathic epilepsy, epileptiform convulsions) in the dog. Because it is rapidly converted into phenobarbital in this species (see Pharmacokinetics below), and has a greater incidence of hepatotoxicity and behavioral effects, most neurologists do not recommend its use. However, some clinicians feel that some animals not responding to phenobarbital do benefit from primidone therapy, perhaps as a result that PEMA has been demonstrated to potentiate the anticonvulsant activity of phenobarbital in animals. When compared with phenobarbital, increased incidence of hepatotoxicity associated with primidone is considered the major limitation to long-term therapy with this agent. Primidone is considered more toxic in rabbits and cats than in humans or dogs.

Pharmacology/Actions

Primidone and its active metabolites, phenylethamalonamide (PEMA) and phenobarbital have similar anticonvulsant actions. While the exact mechanism for this activity is unknown, these agents raise seizure thresholds or alter seizure patterns.

Pharmacokinetics

Primidone is slowly absorbed after oral administration in the dog, with peak levels occurring 2–4 hours after dosing. The bioavailability of primidone in humans has been reported as 60–80%.

Primidone is rapidly converted to PEMA and phenobarbital in the dog. Serum half-lives of primidone, PEMA, and phenobarbital have been reported to be 1.85 hrs, 7.1 hrs, and 41 hours, respectively (Yearly 1980). In the dog, a 250 mg dose of primidone is approximately equivalent to 60 mg of phenobarbital (Platt 2005).

Primidone, like phenobarbital (possibly due to the phenobarbital?), can induce hepatic microsomal enzymes that can increase the rate of metabolism of itself and other drugs.

For more information on the pharmacokinetics of phenobarbital, refer to its monograph.

Contraindications/Precautions/Warnings

Many clinicians and the veterinary manufacturers of primidone feel that primidone is contraindicated in cats, other clinicians dispute this, but it is recommended that primidone be used in cats only with extreme caution. Use cautiously in patients who are hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease. Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction. Primidone is contraindicated in patients with severe liver disease or have had hypersensitivity reactions.

When converting dogs from primidone to phenobarbital, it has been suggested do this slowly (1/4 of the dose each month) (Platt 2005).

Adverse Effects

Adverse effects in dogs are similar for both primidone and phenobarbital. Dogs may exhibit increased clinical signs of anxiety and agitation when initiating therapy. These effects may be transitory in nature and often will resolve with small dosage increases. Occasionally, dogs will exhibit profound depression at lower dosage ranges (and plasma levels). Polydipsia, polyuria, and polyphagia are quite commonly displayed at moderate to high serum levels; these are best controlled by limiting intake of both food and water. Sedation and/or ataxia often become significant concerns as serum levels reach the higher ends of the therapeutic range.

Increases in liver enzymes (ALT, ALP, glutamate dehydrogenase) and decreased serum albumin with chronic therapy are common (up to 70% of dogs treated), and more prevalent than with phenobarbital. Hepatic lipidosis, hepatocellular hypertrophy and necrosis, and extramedullary hematopoiesis can be seen after 6 months of therapy. Serious hepatic injury probably occurs in approximately 6–14% of dogs treated.

In dogs, anorexia, tachycardia, dermatitis, episodic hyperventilation, urolith formation and, rarely, megaloblastic anemia have also been reported with primidone therapy.

Reproductive/Nursing Safety

The effects of primidone in pregnancy are unknown. In pregnant humans, procarbazine is designated by the FDA as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Primidone appears in maternal milk in substantial quantities. It is suggested that if somnolence occurs in nursing newborns to consider discontinue nursing.

Overdosage/Acute Toxicity

Because primidone is rapidly metabolized to phenobarbital in dogs, similar clinical signs (sedation to coma, anorexia, vomiting, nystagmus) are seen and corresponding procedures should be used for the treatment of acute primidone overdose. This includes the removal of ingested product from the gut if appropriate, and offering respiratory and cardiovascular support. Activated charcoal has been demonstrated to be of considerable benefit in enhancing the

clearance of phenobarbital, even when the drug was administered parenterally. Charcoal acts as a “sink” for the drug to diffuse from the vasculature back into the gut. Forced alkaline diuresis can be of considerable benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal or hemodialysis may also be helpful in severe intoxications or in anuric patients.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving primidone or phenobarbital (primidone's active metabolite) and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are given
- **CARBONIC ANHYDRASE INHIBITORS** (e.g., **acetazolamide**): Oral administration may decrease the GI absorption of primidone.
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., **amitraz**, possibly **selegiline**): May prolong phenobarbital effects
- **PHENYTOIN:** Barbiturates may affect the metabolism of phenytoin, and phenytoin may alter barbiturate levels; monitoring of blood levels may be indicated
- **RIFAMPIN:** May induce enzymes that increase the metabolism of barbiturates

The following drugs may increase the effects of phenobarbital:

- **ANTIHISTAMINES**
- **CHLORAMPHENICOL**
- **OPIATES**
- **PHENOTHIAZINES**
- **VALPROIC ACID**

Phenobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:

- **ANTICOAGULANTS, ORAL (WARFARIN)**
- **BETA-BLOCKERS**
- **CHLORAMPHENICOL**
- **CLONAZEPAM**
- **CORTICOSTEROIDS**
- **CYCLOSPORINE**
- **DOXORUBICIN**
- **DOXYCYCLINE** (may persist for weeks after barbiturate discontinued)
- **ESTROGENS**
- **GRISEOFULVIN**
- **METHADONE**
- **METRONIDAZOLE**
- **QUINIDINE**
- **PAROXETINE**
- **PHENOTHIAZINES**
- **PROGESTINS**
- **THEOPHYLLINE**
- **TRICYCLIC ANTIDEPRESSANTS**
- **VERAPAMIL**

Laboratory Considerations

- Barbiturates may cause increased retention of **bromosulfophthalein** (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests; or if they must, (e.g., for seizure control) the results be interpreted accordingly.

- Phenobarbital can alter **thyroid** testing. Decreased total and free T4, normal T3, and either normal or increased TSH have been reported. It has been suggested to wait at least 4 weeks after discontinuing phenobarbital to perform thyroid testing.
- In some dogs, phenobarbital may cause a false positive low dose **dexamethasone suppression test**, by increasing the clearance of dexamethasone. Phenobarbital apparently has no effect either on ACTH stimulation tests or on the hormonal equilibrium of the adrenal axis.

Doses

■ DOGS:

- a) Initially, 10–30 mg/kg per day divided into 2–3 doses (LeCouteur 1999)
- b) 10 mg/kg PO q8h; not recommended as first choice (Taylor 2003b)

■ CATS:

- a) 11–22 mg/kg three times daily (Davis 1985b)
- b) 20 mg/kg, PO q12h (Neff-Davis 1985)

Monitoring

- Anticonvulsant efficacy
- Adverse effects (CNS related, PU/PD, weight gain)
- Serum phenobarbital levels if lack of efficacy or adverse reactions noted. Although there is some disagreement, therapeutic serum levels in dogs are thought to mirror those in people at 15–40 micrograms/mL. See the phenobarbital monograph for more information.
- If used chronically, routine CBCs and liver enzymes at least every 6 months

Client Information

- Compliance with therapy must be stressed to clients for successful epilepsy treatment. Encourage giving daily doses at same time each day.
- Veterinarian should be contacted if animal develops significant adverse reactions (including clinical signs of anemia and/or liver disease) or if seizure control is unacceptable.

Chemistry/Synonyms

An analog of phenobarbital, primidone occurs as a white, odorless, slightly bitter-tasting, crystalline powder with a melting point of 279°–284°C. One gram is soluble in approximately 2000 mL of water or 200 mL of alcohol.

Primidone may also be known as: hexamidineum, primaclone, primidonum, *Cyral*®, *Epidona*®, *Liskantin*®, *Mylopsinum*®, *Mysoline*®, *Neurosyn*®, *Prysoline*®, *Resimatil*®, or *Sertan*®.

Storage/Stability

Tablets should be stored in well-closed containers preferably at room temperature. The oral suspension should be stored in tight, light-resistant containers preferably at room temperature; avoid freezing. Commercially available suspension and tablets generally have expiration dates of 5 years after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Primidone Tablets: 50 mg and 250 mg; *Neurosyn*® (Boehringer Ingelheim); generic; (Rx). Approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Primidone Tablets: 50 mg & 250 mg; *Mysoline*® (Xcell Pharm); generic; (Rx)

PROBENECID

(proh-ben-eh-sid) Benemid®, Benuryl®

URICOSURIC; RENAL TUBULAR SECRETION INHIBITOR**Prescriber Highlights**

- ▶ Uricosuric & renal tubular secretion inhibitor that may be useful for treating gout (particularly in reptiles)
- ▶ Probenecid is associated with many drug interactions as it inhibits the renal tubular secretion of numerous drugs, including several beta-lactam antibiotics; some interactions may be beneficial, others may increase potential for toxicity
- ▶ Little experience using this drug in mammals other than humans

Uses/Indications

Although there has been very limited clinical use or research on probenecid in veterinary medicine, it can be useful in treating gout (hyperuricemia), particularly in reptiles.

Probenecid's effect in inhibiting renal tubular secretion of certain beta-lactam antibiotics and other weak organic acids is of interest for increasing serum concentrations, or reducing doses and dosing frequency of these drugs. This may allow greater efficacy (but also toxic effects) and reduce the cost or dosing frequency of expensive human drugs. Probenecid has a significantly long elimination half-life in dogs (about 18 hours), which may make it particularly useful in this species; however, at present there is little research supporting this use of probenecid in veterinary patients.

Pharmacology/Actions

Probenecid reduces serum uric acid concentrations by enhancing uric acid excretion into the urine by competitively inhibiting urate reabsorption at the proximal renal tubules.

Probenecid competitively inhibits tubular secretion of weak organic acids including the penicillins, some cephalosporins (not ceftriaxone, ceftazidime, or cefoperazone), sulbactam and tazobactam (not clavulanic acid), oseltamivir, etc.

Pharmacokinetics

There is limited information available for veterinary species. In dogs, information on oral bioavailability was not located, but after intravenous administration the distribution half-life was 2.3 hours and apparent volume of distribution at steady state was 0.46 L/kg. Probenecid exhibits biphasic concentration dependent plasma protein binding characteristics in the dog and appears to bind less to plasma proteins than in humans. Plasma clearance was 0.343 mL/min/kg and elimination half-life was 17.7 hours, which is considerably longer than in humans (6.5 hrs) or sheep (1.55 hrs) (Kakizaki, Yokoyama et al. 2005).

After administration to mares, probenecid had an oral bioavailability of approximately 90%. The drug is highly bound (99.9%) to equine plasma proteins. Elimination half-life is approximately 90–120 minutes.

In humans, absorption after oral administration is rapid and complete. The drug is converted in the liver to glucuronidated, carboxylated, and hydroxylated compounds that have uricosuric and renal tubular secretion inhibition activity. Elimination half-life is dosage dependent and large dosages (above 500 mg) have longer half-lives.

Contraindications/Precautions/Warnings

Probenecid should not be used in patients with, or susceptible to, uric acid renal or bladder calculus formation or urate nephropathy (e.g., cancer chemotherapy with rapidly cytolytic agents). Probenecid requires sufficient renal function to be effective; efficacy decreases with increasing renal function impairment. The drug has no efficacy in human patients with a creatine clearance of less than 30 mL/min.

Probenecid is not usually recommended for treating gout in birds as it can exacerbate the condition.

Adverse Effects

An accurate adverse effect profile for probenecid has not been determined for animal patients. In humans, probenecid occasionally causes headache, gastrointestinal effects (inappetence, nausea, mild vomiting), or rashes. When used for gout, it can initially cause an increased rate of gouty attacks unless prophylaxis with colchicine is used concurrently. Rarely, hypersensitivity, bone marrow suppression, hepatotoxicity, or nephrotic syndrome have been reported in humans.

Reproductive/Nursing Safety

Probenecid apparently crosses the placenta, but adverse effects to fetuses have not been reported. In humans, the FDA categorizes probenecid as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if probenecid enters milk, but it is unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity

Limited information is available. One massive (>45 g) overdose in a human patient caused CNS stimulation, seizures, protracted vomiting and respiratory failure.

Consider contacting an animal poison control center for guidance with large overdoses. Generally, probenecid overdoses should initially be handled using standardized protocols for removal of drug from the gut and preventing absorption. Treat supportively, but use caution co-administering drugs that may compete with probenecid for tubular secretion.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving probenecid and may be of significance in veterinary patients:

- **ACYCLOVIR:** Increased acyclovir serum concentrations; probenecid can decrease renal excretion
- **ANTINEOPLASTICS (rapidly cytolytic):** Increased chance of uric acid nephropathy
- **ASPIRIN (and other salicylates):** Salicylates antagonize the uricosuric effects of probenecid
- **BENZODIAZEPINES (lorazepam, oxazepam):** Probenecid may prolong action or reduce time for onset of action

- **BETA-LACTAM ANTIBIOTICS** (including **penicillins** and **some cephalosporins**): Probenecid may increase serum concentrations by reducing renal excretion
- **BETA-LACTAMASE INHIBITORS** (including **sulbactam** and **tazobactam**, but **not clavulanic acid**): Probenecid may increase serum concentrations by reducing renal excretion
- **CHLORPROPAMIDE** (and **potentially other sulfonylureas**): Probenecid decreases elimination; hypoglycemia is possible
- **CIPROFLOXACIN**: Probenecid reduces renal tubular secretion by about 50%
- **DAPSONE**: Possible accumulation of dapsone or its active metabolites
- **FUROSEMIDE**: Increased serum furosemide levels
- **HEPARIN**: Probenecid may increase and prolong heparin's effects
- **METHOTREXATE**: Probenecid may increase levels; increased risks for toxicity
- **NSAIDS** (including **carprofen**, **ketoprofen** & **potentially others**): Probenecid may increase plasma levels and increase risks for toxicity
- **NITROFURANTOIN**: Reduced urine levels; increased chance for systemic toxicity
- **OSELTAMIVIR**: Probenecid may increase serum concentrations by reducing renal excretion
- **RIFAMPIN**: Probenecid may reduce hepatic uptake of rifampin and serum levels can be increased; use together is not recommended as effect is inconsistent and can lead to toxicity
- **SULFONAMIDES**: Probenecid decreases renal elimination of sulfonamides, but as free serum concentrations of sulfonamides are not increased this interaction is not therapeutically beneficial and may increase risks for sulfonamide toxicity
- **THIOPENTAL**: Anesthesia may be extended or dose required for anesthesia decreased

Laboratory Considerations

The following laboratory alterations have been reported in humans with probenecid and may be of significance in veterinary patients:

- **Urine glucose determinations**: When using cupric sulfate solution (Benedict's Solution, *Clinitest*®): Probenecid may cause false-positive results. Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected.
- **Theophylline levels**: Serum theophylline levels may be falsely elevated (Schack and Waxtler technique)
- **17-ketosteroid concentrations in urine**: May be decreased
- **Phosphorus**: Probenecid may increase phosphorus reabsorption in hypoparathyroid patients
- **Aminohippuric acid (PAH) or Phenolsulphonphthalein (PSP) clearance studies**: Probenecid decreases renal clearance
- **Renal function studies using iodohippurate sodium I 123 or I 131, or technetium TC 99**: Decreased kidney uptake
- **Homovanillic acid (HVA) or 5-Hydroxyindoleacetic acid (5-HIAA)**: Probenecid inhibits transport from CSF into blood

Doses

■ REPTILES:

For gout:

- a) 250 mg PO q12h; can be increased as needed. Suggested dosage based upon human data as dose is not established for reptiles. (Johnson-Delaney 2005d)
- b) 40 mg/kg PO q12h (Coke 2004)
- c) 250 mg PO twice daily; may increase as needed. (de la Navarre 2003a)

Monitoring

- Depending on purpose for use: serum and urine uric acid, if concomitant urine alkalinization is used, consider monitoring acid-base balance

Client Information

- In small animals, there is little scientific data supporting using probenecid for increasing blood levels of drugs that compete with probenecid for renal excretion; probenecid's adverse effects are not well known in these patients

Chemistry/Synonyms

Probenecid is a sulfonamide derivative that occurs as a white, to practically white, practically odorless, fine, crystalline powder. It is practically insoluble in water and soluble in alcohol.

Probenecid may also be known as: probenecidas, probenecidum, *Benemid*® and *Benuryl*®.

Storage/Stability

Probenecid tablets should be stored at room temperature in well-closed containers. Expiration dates are generally 3–5 years after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Probenecid Tablets: 0.5 g (500 mg); generic; (Rx)

Also available as fixed-dose tablets containing probenecid 500 mg and colchicine 0.5 mg, but this dosage form is unlikely to be useful in veterinary patients.

PROCAINAMIDE HCL

(proe-kane-a-mide) Pronestyl®

ANTIARRHYTHMIC

Prescriber Highlights

- Antiarrhythmic used primarily for treatment of ventricular premature complexes (VPC's), ventricular tachycardia; efficacy is questionable in dogs
- Contraindications: Myasthenia gravis; hypersensitive to drug, procaine or other chemically related drugs; torsade de pointes; or 2nd or 3rd degree heart block (unless artificially paced)
- Extreme Caution: Cardiac glycoside intoxication, systemic lupus; Caution: Significant hepatic, renal disease or CHF
- Adverse Effects: DOGS: Blood level related: GI effects, weakness, hypotension, negative inotropism, widened QRS complex & QT intervals, AV block, multiform ventricular tachycardias. Possible: fevers & leukopenias
- Profound hypotension can occur if injected too rapidly IV
- Consider dosage reduction in patients with renal failure, CHF, or critically ill
- Drug Interactions

Uses/Indications

Procainamide potentially may be useful for the treatment of ventricular premature complexes (VPC's), ventricular tachycardia, or supraventricular tachycardia associated with Wolff-Parkinson-White (WPW) syndrome with wide QRS complexes. Higher doses may be beneficial in the treatment of supraventricular tachycardias, although procainamide cannot be considered a first-line agent for this dysrhythmia.

Pharmacology/Actions

A class 1A antiarrhythmic agent, procainamide exhibits cardiac action similar to that of quinidine. It is considered both a supraventricular and ventricular antidysrhythmic. Procainamide prolongs the refractory times in both the atria and ventricles, decreases myocardial excitability, and depresses automaticity and conduction velocity. It has anticholinergic properties that may contribute to its effects. Procainamide's effects on heart rate are unpredictable, but it usually causes only slight increases or no change. It may exhibit negative inotropic actions on the heart, although cardiac outputs are generally not affected.

On ECG, QRS widening, and prolonged PR and QT intervals can be seen. The QRS complex and T wave may occasionally show some slight decreases in voltage.

Pharmacokinetics

After IM or IV administration, the onset of action is practically immediate. After oral administration in humans, approximately 75–95% of a dose is absorbed in the intestine, but some patients absorb less than 50% of a dose. Food, delayed gastric emptying, or decreased stomach pH may delay oral absorption. In dogs, it has been reported that the oral bioavailability is approximately 85% and the absorption half-life is 0.5 hours; however, there is an apparent large degree of variability in both bioavailability and half-life of absorption.

Distribution of procainamide is highest into the CSF, liver, spleen, kidneys, lungs, heart and muscles. The volume of distribution in dogs is approximately 1.4–3 L/kg. It is only approximately 20% protein bound in humans and 15% in dogs. Procainamide can cross the placenta and is excreted into milk.

The elimination half-life in dogs has been reported to be variable; most studies report values between 2–3 hours. In humans, procainamide is metabolized to N-acetyl-procainamide (NAPA), an active metabolite. It appears, however, that dogs do not form appreciable amounts of NAPA from procainamide as they are unable to appreciably acetylate aromatic and hydrazine amino groups. In the dog, approximately 90% (50–70% unchanged) of an intravenous dose is excreted in the urine as procainamide and metabolites within 24 hours after dosing.

Contraindications/Precautions/Warnings

Procainamide may be contraindicated in patients with myasthenia gravis (see Drug Interactions). Procainamide is contraindicated in patients hypersensitive to it, procaine or other chemically related drugs. In humans, procainamide is contraindicated in patients with systemic lupus erythematosus (SLE), but it is unknown if it adversely affects dogs with this condition. Procainamide should not be used in patients with torsade de pointes, or with 2nd or 3rd degree heart block (unless artificially paced).

Procainamide should be used with extreme caution, if at all, in patients with cardiac glycoside intoxication. It should be used with caution in patients with significant hepatic or renal disease or with congestive heart failure.

It has been recommended to not use procainamide in Doberman pinschers and boxers with dilated cardiomyopathy or dogs with subaortic stenosis; the drug may be proarrhythmic in certain patients susceptible to tachyarrhythmic-induced sudden death. (Kittleson 2006c)

Adverse Effects

Adverse effects are generally dosage (blood level) related in the dog. Gastrointestinal effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension, negative inotropism, widened QRS complex and QT intervals, AV block, multiform ventricular tachycardias. Fevers and leukopenias are a possibility. Profound hypotension can occur if injected too rapidly IV. In humans an SLE syndrome can occur, but its incidence has not been established in the dog.

Dosages should usually be reduced in patients with renal failure, congestive heart failure, or those who are critically ill.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Both procainamide and NAPA are excreted in maternal milk and absorbed in nursing offspring. It should be used with caution in nursing patients; consider using milk replacer if the drug is to be continued.

Overdosage/Acute Toxicity

Clinical signs of overdosage can include hypotension, lethargy, confusion, nausea, vomiting, and oliguria. Cardiac signs may include widening of the QRS complex, junctional tachycardia, ventricular fibrillation, or intraventricular conduction delays.

If an oral ingestion, emptying of the gut and charcoal administration may be beneficial to remove any unabsorbed drug. IV fluids, plus dopamine, phenylephrine, or norepinephrine could be considered to treat hypotensive effects. A 1/6 molar intravenous infusion of sodium lactate may be used in an attempt to reduce the cardiotoxic effects of procainamide. Forced diuresis using fluids and diuretics along with reduction of urinary pH can enhance the renal excretion of the drug. Temporary cardiac pacing may be necessary should severe AV block occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving procainamide and may be of significance in veterinary patients:

Use with caution with other antidysrhythmic agents, as additive cardiotoxic or other toxic effects may result.

- **AMIODARONE:** May increase procainamide levels, procainamide dose may need to be reduced
- **ANTICHOLINESTERASE AGENTS** (e.g., pyridostigmine, neostigmine): Procainamide may antagonize effects in patients with myasthenia gravis
- **CIMETIDINE:** May increase procainamide levels
- **HYPOTENSIVE DRUGS:** Procainamide may enhance effect
- **LIDOCAINE:** Toxic effects may be additive, and cardiac effects unpredictable

- **NEUROMUSCULAR BLOCKING AGENTS:** Procainamide may potentiate or prolong the neuromuscular blocking activity
- **QUINIDINE:** Toxic effects may be additive, and cardiac effects unpredictable
- **PHENYTOIN:** Toxic effects may be additive, and cardiac effects unpredictable
- **PROPRANOLOL:** Toxic effects may be additive, and cardiac effects unpredictable
- **RANITIDINE:** May increase procainamide levels
- **TRIMETHOPRIM:** May increase procainamide levels

Doses

■ DOGS:

- a) For ventricular tachyarrhythmias: When used IV: intermittent boluses of 2–4 mg/kg IV slowly (over two minutes) up to a total dose of 12–20 mg/kg until arrhythmia controlled and then a CRI may be started at 10–40 mcg/kg/minute. PO use at: 20–30 mg/kg PO q6–8h (could be too low—previous recommendations of 8–20 mg/kg PO q6–8h are almost certainly too low). (Kittleson 2006c)
- b) For acute management of SVT's: After drugs have been used to slow AV nodal conduction (*i.e.*, diltiazem), procainamide at 6–8 mg/kg IV over 3 minutes or 6–20 mg/kg IM may terminate atrial tachyarrhythmias.
For chronic management: 10–20 mg/kg PO q6–8h; higher dosages of up to 40 mg/kg q6h have been necessary to treat junctional SVT's in some dogs (Wright 2000)
- c) For ventricular tachycardia: For acute treatment of VT: 10–15 mg/kg IV bolus over 1–2 minutes; if continued parenteral administration required may use a constant rate IV infusion at 25–50 mcg/kg/minute. For chronic treatment: 10–20 mg/kg PO q6h (Moise 2000)
- d) For ventricular tachycardia: 6.6–8.8 mg/kg slowly IV over 5 minutes, then give as a CRI at 40–100 mcg/kg/minute. (Fine 2006)
- e) For chronic treatment of ventricular arrhythmias: 20–23 mg/kg PO q8h (Meurs 2002)
- f) Using sustained-release tablets: 20 mg/kg PO q8h; For intravenous therapy: 6–8 mg/kg IV bolus, 20–40 mcg/kg/min CRI (Hogan 2004)

■ CATS:

For chronic management of SVT's:

- a) 3–8 mg/kg PO q6–8h. (Wright 2000)
- b) 1–2 mg/kg slowly IV; 10–20 mcg/kg/minute constant rate IV infusion. Oral dose: 7.5–20 mg/kg q (6 to) 8h (Ware 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) For atrial fibrillation (not as effective as quinidine); also has been used for ventricular tachycardia: IV at 1 mg/kg/min, not too exceed 20 mg/kg (20 minutes) total dose. Alternatively administer 25–35 mg/kg PO q8h. (Kimberly and McGurrin 2006)
- b) For V-Tach: 1 mg/kg/minute IV up to a total dose of 20 mg/kg; or 25–35 mg/kg PO q8h (Mogg 1999)

Monitoring

- ECG; continuously with IV dosing
- Blood pressure, during IV administration
- Clinical signs of toxicity (see Adverse Effects/Overdosage)
- Serum levels

Because of the variability in pharmacokinetics reported in the dog, it is recommended to monitor therapy using serum drug levels. Because dogs apparently do not form the active metabolite NAPA in appreciable quantities, the therapeutic range for procainamide is controversial. Therapeutic ranges from 3–8 mcg/mL to 8–20 mcg/mL have been suggested. This author would suggest using the lower range as a guideline to initiate therapy, but not to hesitate increasing doses to attain the higher values if efficacy is not achieved and toxicity is not a problem. Digitalis-induced ventricular arrhythmias may require substantially higher blood levels for control. Trough levels are usually specified when monitoring oral therapy. Because NAPA is routinely monitored with procainamide in human medicine, it may be necessary to request to the laboratory that NAPA values need not be automatically run for canine patients.

In horses, therapeutic levels have been suggested as 4–10 mcg/mL for procainamide and 10–30 mcg/dl as procainamide and NAPA together. (Kimberly and McGurrin 2006)

Client Information

- Oral products should be administered at evenly spaced intervals throughout the day/night. Unless otherwise directed, give the medication at least 1 hour before feeding to animal with an empty stomach.
- Notify veterinarian if animal's condition deteriorates or clinical signs of toxicity (*e.g.*, vomiting, diarrhea, weakness, etc.) occur.

Chemistry/Synonyms

Structurally related to procaine, procainamide is used as an anti-arrhythmic agent. Procainamide HCl differs from procaine by the substitution of an amide group for the ester group found on procaine. It occurs as an odorless, white to tan, hygroscopic, crystalline powder with a pK_a of 9.23 and a melting range from 165°–169°C. It is very soluble in water and soluble in alcohol. The pH of the injectable product ranges from 4–6.

Procainamide may also be known as: novocainamidum, procainamidi chloridum, procainamidi hydrochloridum, *Biocoryl*®, *Procan*®, *Procanbid*®, or *Pronestyl*®.

Storage/Stability/Compatibility

The solution may be used if the color is no darker than a light amber. Refrigeration may retard the development of oxidation, but the solution may be stored at room temperature.

The injectable product is reportedly physically **compatible** with sodium chloride 0.9% injection, and water for injection. Procainamide is also physically **compatible** with dobutamine HCl, lidocaine HCl, and verapamil HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Procainamide HCl Injection: 500 mg/mL in 2 mL vials; generic; (Rx)

Procainamide HCl Capsules: 250 mg, 375 mg & 500 mg; generic; (Rx)

Procainamide HCl Tablets: 375 mg & 500 mg; *Pronestyl®* (Apothecon); (Rx)

Procainamide HCl Extended-Release Tablets: 250 mg, 500 mg, 750 mg & 1000 mg (**Note:** These products are not recommended for initial therapy and have not been extensively used in veterinary medicine.); *Procanbid®* (Monarch); generic; (Rx)

PROCARBAZINE HCL

(proe-kar-ba-zeen) Matulane®

ANTINEOPLASTIC**Prescriber Highlights**

- ▶ Atypical alkylating agent that is used in MOPP lymphoma protocols for dogs/cats & for GME in dogs; enters CNS
- ▶ Contraindications: Hypersensitivity to drug, inadequate bone marrow reserve
- ▶ Caution: Hepatic/renal impairment, use with other CNS depressant drugs
- ▶ Adverse Effects: GI, myelosuppression, central & peripheral nervous system, hepatic
- ▶ Teratogen
- ▶ Drug interactions
- ▶ May need to be reformulated in an oil-based solution to dose appropriately; commercial preparation is very expensive

Uses/Indications

In veterinary medicine, procarbazine is used as part of MOPP protocols (mechlorethamine, vincristine, procarbazine, prednisone) to treat lymphomas in dogs and cats. It may be of benefit in treating granulomatous meningoencephalitis (GME) in dogs.

Pharmacology/Actions

Procarbazine's precise mode of action is not well understood, but it is considered by most to be an alkylating agent, as it appears to inhibit protein, RNA, and DNA synthesis. Procarbazine is auto-oxidized into hydrogen peroxide, which may also directly damage DNA.

Pharmacokinetics

No data specific for dogs or cats was located. In humans, procarbazine is well absorbed after oral administration and rapidly equilibrates between the CSF and plasma. Peak levels in plasma occur in about one hour; in the CSF, about 30–90 minutes after dosing. Procarbazine is almost entirely metabolized in the liver and kidney. Metabolic products are cytotoxic and excreted in the urine.

Contraindications/Precautions/Warnings

Procarbazine is contraindicated in patients known to be hypersensitive to it or with inadequate bone marrow reserve as determined by bone marrow aspirate.

Because procarbazine can cause CNS depression, use with extreme caution with other CNS depressant drugs.

Use with caution in patients with impaired renal or hepatic function.

Adverse Effects

When dosed as recommended for dogs and cats, procarbazine is relatively well tolerated. In dogs, procarbazine toxicity appears to mirror that seen in humans. Gastrointestinal effects (nausea, vomiting, hepatotoxicity) and myelosuppression (thrombocytopenia, leukopenia) can be seen. Thrombocytopenia nadirs usually occur at about 4 weeks. Because it is often used in combination with other chemotherapy agents (MOPP), myelosuppression and GI effects (hemorrhagic gastritis) may be enhanced. CNS effects may be noted and include sedation or agitation. Peripheral neuropathy can occur and includes loss of tendon reflexes, paresthesias and myalgia.

In humans, it is recommended to discontinue therapy if any of the following occur: CNS signs, leukopenia (WBC <4000 mm³), thrombocytopenia (platelets <100,000 mm³), hypersensitivity, stomatitis (at sign of first ulceration), diarrhea, and hemorrhage or bleeding. Resume therapy at a lower dosage only when effects clear.

Reproductive/Nursing Safety

Procarbazine is potential teratogen. In pregnant humans, procarbazine is designated by the FDA as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown if procarbazine enters milk. It is recommended to use milk replacer if the dam requires procarbazine.

Overdosage/Acute Toxicity

The LD₅₀ for laboratory animals range from 150 mg/kg (rabbits) to 1.3 g/kg (mice). Treat overdoses aggressively to remove drug from the gut if overdose was within an hour or two. Anticipated adverse effects would be extensions of the drug's adverse effect profile (GI, bone marrow suppression, CNS effects). Monitor and support as necessary. Contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving procarbazine and may be of significance in veterinary patients:

- **ALCOHOL:** May cause severe nausea and vomiting
- **CNS DEPRESSANT DRUGS** (e.g., barbiturates, opiates, antihistamines, phenothiazines, etc.): Because procarbazine can cause CNS depression, use with extreme caution with other CNS depressant drugs. Coma and death have been reported when procarbazine has been used with opiates.
- **FOODS WITH HIGH TYRAMINE CONTENT** (aged cheese, yogurt): Procarbazine exhibits some monoamine oxidase inhibitory (MAOI) activity; serious hypertension may result
- **SYMPATHOMIMETICS** (phenylpropanolamine, etc.): Procarbazine exhibits some monoamine oxidase inhibitory (MAOI) activity; serious hypertension may result
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., clomipramine, amitriptyline, etc.): Procarbazine exhibits some monoamine oxidase inhibitory (MAOI) activity. Do not use concurrently with tricyclic antidepressant drugs.

Laboratory Considerations

None were noted

Doses

■ DOGS:

For lymphoma rescue:

a) For MOPP lymphoma rescue: Mechlorethamine: 3 mg/m² IV days 1 and 7; Vincristine: 0.7 mg/m² IV days 1 and 7; Procarbazine: 50 mg/m² PO daily days 1–14; Prednisone: 30 mg/m² PO daily day 1–14. No treatment given days 15–28 and then protocol is repeated at 4 weeks. Protocol may be severely myelosuppressive. (Meleo 2003)

b) Using the DOPP protocol (particularly when mechlorethamine is not available):

Substitute Dactinomycin: 0.5 mg/m² IV days 0 and 7;

Vincristine: 0.7 mg/m² IV days 0 and 7;

Procarbazine: 50 mg/m² (for dogs >0.8 mg/m² give dose to the nearest 50 mg; >0.4 mg, but <0.8 mg/m² give to the nearest 50 mg, but give every other day; dogs <0.4 mg/m² reformulate into 10 mg capsules and give to the nearest 20 mg) PO daily days 0–13;

Prednisone: 30–40 mg/m² PO daily days 0–13.

No treatment given days 15–28 and then protocol is repeated at 4 weeks. Protocol may be severely myelosuppressive. Evaluate CBC on days 7 and 28. If neutrophil count is <2,000 cells/mcL, delay treatment for 3 days and recheck; monitor for cumulative thrombocytopenia. (Rassnick 2006)

For treatment of granulomatous meningoencephalitis (GME):

a) 25–50 mg/m² PO once daily, initially with prednisone treatment. After the first month of therapy, we attempt to reduce procarbazine dose to every other day. Monitor CBC weekly for first month, and then monthly thereafter. Wear gloves when handling. To prepare a 10 mg/mL oil-based solution: Five 50 mg capsules, oil-based flavor (chicken, liver, fish) drops, 0.25 teaspoonful of silica gel (to keep in suspension), and gradually add sesame oil to a total of 25 mL. Assigned expiration date of 30 days. (Cuddon and Coates 2002)

■ CATS:

For MOPP lymphoma rescue:

a) Mechlorethamine: 3 mg/m² IV days 1 and 7; Vincristine: 0.5 mg/m² IV days 1 and 7; Procarbazine: 50 mg/m² PO daily days 1–14; Prednisone: 30 mg/m² PO daily day 1–14. No treatment given days 15–28 and then protocol is repeated at 4 weeks. Cats may require 5 week cycle due to myelosuppression. (Meleo 2003)

b) Mechlorethamine: 3 mg/m² IV days 0 and 7; Vincristine: 0.025 mg/kg IV days 0 and 7; Procarbazine: 10 mg (total dose) PO daily days 0–14; Prednisone: 5 mg (total dose) PO twice daily continuously. May also be considered for inducing first remission in cats. Anorexia may be reduced if procarbazine is given every other day or given with metoclopramide. (Frimberger 2002)

Monitoring

- Baseline: CBC, hepatic and renal function, urinalysis
- Repeat CBC at least once weekly for the first month of treatment and then monthly
- In humans, it is recommended to repeat urinalysis, transaminases/alkaline phosphatase, and BUN at least weekly

Client Information

- Avoid skin contact with the medication. Wear gloves or wash hands thoroughly after dosing. Avoid contact with patient's saliva or urine.

- Contact veterinarian immediately if any signs associated with toxicity occur. These could include vomiting, lack of appetite, diarrhea, bleeding, depression or agitation, bleeding, sores in mouth, lameness, etc.

Chemistry/Synonyms

A derivative of hydrazine, procarbazine HCl occurs as a white to pale yellow crystalline powder having a slight odor. It is soluble, but unstable in water or aqueous solutions.

Procarbazine may also be known as: Ibenzemethyzin, NSC-77213, Ro-4-6467/1, MIH, N-Methylhydrazine, *Matulane*®, *Natulan*®, and *Natulanar*®.

Storage/Stability/Compatibility

Procarbazine capsules should be stored in airtight containers, protected from light at temperatures less than 40°C (preferably between 15–30°C, (59–86°F)). An expiration date of 4 years is assigned after the date of manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Procarbazine HCl Capsules: 50 mg; *Matulane*® (SigmaTau); (Rx)

PROCHLORPERAZINE

(proe-klor-per-a-zeen) Compazine®, Compro®

PHENOTHIAZINE ANTIEMETIC

Prescriber Highlights

- Phenothiazine used alone as an antiemetic; formerly in combination with an anticholinergic for other GI effects (e.g., diarrhea)
- Relative Contraindications: Hypovolemia or shock & in patients with tetanus or strychnine intoxication
- Caution: Hepatic dysfunction, cardiac disease, general debilitation, or very young animals
- Adverse Effects: Sedation or hypotension

Uses/Indications

Prochlorperazine as a single agent is used in dogs and cats as an antiemetic. The only approved products for animals are combination products containing prochlorperazine, isopropamide, with or without neomycin (*Darbazine*®, *Neo-Darbazine*®—SKB Labs) which are no longer marketed in the USA. The approved indications for these products include: vomiting, non-specific gastroenteritis, drug induced diarrhea, infectious diarrhea, spastic colitis, and motion sickness in dogs and cats (injectable product only).

Pharmacology/Actions

The basic pharmacology of prochlorperazine is similar to that of the other phenothiazines (refer to the acepromazine monograph for more information). Prochlorperazine has weak anticholinergic effects, strong extrapyramidal effects, and moderate sedative effects. It has a strong antiemetic effect which is its primary reason for use in both human and veterinary medicine.

Pharmacokinetics

Little information is available regarding the pharmacokinetics of prochlorperazine in animals, although it probably follows the general patterns of other phenothiazine agents in absorption, distribution, and elimination.

Contraindications/Precautions/Warnings

Animals may require lower dosages of general anesthetics following phenothiazines. Cautious use and smaller doses of phenothiazines should be given to animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of their hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia or shock. It should not be used for tetanus or strychnine intoxication due to effects on the extrapyramidal system. Use cautiously in very young or debilitated animals.

Adverse Effects

Alone, prochlorperazine is most likely to cause sedation or hypotension.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

A related compound, chlorpromazine has been detected in maternal milk. Although few cases are documented, a milk to plasma ratio of 0.5–0.7 or less is reported. Prochlorperazine is unlikely to pose significant risk to nursing animals.

Overdosage/Acute Toxicity

Refer to the information listed in the acepromazine monograph. Acute extrapyramidal clinical signs (torticollis, tremor, salivation) have been successfully treated with injectable diphenhydramine in humans.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving prochlorperazine or other phenothiazines and may be of significance in veterinary patients:

- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTIDIARRHEAL MIXTURES** (e.g., **Kaolin/pectin, bismuth subsalicylate mixtures**): May cause reduced GI absorption of oral phenothiazines
- **CNS DEPRESSANT AGENTS** (**barbiturates, narcotics, anesthetics**, etc.): May cause additive CNS depression if used with phenothiazines
- **DOPAMINE:** Phenothiazines may decrease pressor effects
- **EPINEPHRINE:** Phenothiazines block alpha-adrenergic receptors and concomitant epinephrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- **METOCLOPRAMIDE:** Phenothiazines may potentiate the extrapyramidal effects of metoclopramide
- **OPIATES:** May enhance the hypotensive effects of the phenothiazines; dosages of prochlorperazine may need to be reduced when used with an opiate

- **ORGANOPHOSPHATE AGENTS:** Phenothiazines should not be given within one month of worming with these agents as their effects may be potentiated
- **PARAQUAT:** Toxicity of the herbicide paraquat may be increased by prochlorperazine
- **PHENYTOIN:** Metabolism may be decreased if given concurrently with phenothiazines
- **PHYSOSTIGMINE:** Toxicity may be enhanced by prochlorperazine
- **PROCAINE:** Activity may be enhanced by phenothiazines
- **PROPRANOLOL:** Increased blood levels of both drugs may result if administered with phenothiazines
- **WARFARIN:** Prochlorperazine may decrease anticoagulant effect

Doses

■ DOGS:

As an antiemetic:

- a) 0.5 mg/kg IM or SC q8h; ensure adequate hydration (Washabau and Elie 1995), (Simpson 2003c), (Marks 2006)
- b) 0.1 mg/kg IM q6–8h; use with extreme caution in dehydrated or hypotensive animals. (Silverstein 2003)
- c) 0.1–0.5 mg/kg IM or SC q6–8h (Otto 2005)

■ CATS:

As an antiemetic:

- a) 0.5 mg/kg SC or IM three times a day; ensure adequate hydration (Simpson 2003c)
- b) 0.5 mg/kg IM or SC q8h (Washabau and Elie 1995), (Marks 2006)
- c) 0.1–0.5 mg/kg IM or SC q6–8h (Otto 2005)

Monitoring

- Cardiac rate/rhythm/blood pressure if indicated and possible to measure
- Anti-emetic/anti-spasmodic efficacy; hydration and electrolyte status
- Body temperature (especially if ambient temperature is very hot or cold)

Client Information

- Observe animal for at least one hour following dosing. Dry mouth may be relieved by applying small amounts of water to animal's tongue for 10–15 minutes.
- May discolor the urine to a pink or red-brown color; this is not abnormal.
- Protracted vomiting and diarrhea can be serious; contact veterinarian if clinical signs are not alleviated. Contact veterinarian if animal exhibits abnormal behavior, becomes rigid or displays other abnormal body movements.

Chemistry/Synonyms

Prochlorperazine, a piperazine phenothiazine derivative, is available commercially as the base in rectal formulations, the edisylate salt in injectable and oral solutions, and as the maleate salt in oral tablets and capsules. Each 8 mg of the maleate salt and 7.5 mg of the edisylate salt are approximately equivalent to 5 mg of prochlorperazine base.

The base occurs as a clear, to pale yellow, viscous liquid that is very slightly soluble in water and freely soluble in alcohol. The edisylate salt occurs as white to very light yellow, odorless, crystalline powder. 500 mg are soluble in 1 mL of water and 750 mL of alcohol. The maleate salt occurs as a white or pale yellow, practically odorless, crystalline powder. It is practically insoluble in water or alcohol.

The commercial injection is a solution of the edisylate salt in sterile water. It has a pH of 4.2–6.2.

Prochlorperazine may also be known as: chlormepazine, prochlorpemazine, *Compazine*®, *Compro*®, *Prochlor*®, *Prorazin*®, *Stemetil*®, or *Tementil*®.

Storage/Stability/Compatibility

Store in tight, light resistant containers at room temperature. Avoid temperatures above 40°C and below freezing. A slight yellowing of the oral or injectable solution has no effects on potency or efficacy, but do not use if a precipitate forms or the solution is substantially discolored.

The following products have been reported to be physically **compatible** when mixed with prochlorperazine edisylate injection: all usual IV fluids, ascorbic acid injection, atropine sulfate, butorphanol tartrate, chlorpromazine HCl, dexamethasone sodium phosphate, droperidol, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, lidocaine HCl, meperidine HCl, metoclopramide, morphine sulfate, nafcillin sodium, nalbuphine HCl, pentazocine lactate, perphenazine, promazine HCl, promethazine, scopolamine HBr, sodium bicarbonate, and vitamin B complex with C.

The following drugs have been reported to be physically **incompatible** when mixed with prochlorperazine edisylate: aminophylline, amphotericin B, ampicillin sodium, calcium gluceptate, chloramphenicol sodium succinate, chlorothiazide sodium, dimenhydrinate, hydrocortisone sodium succinate, methohexital sodium, penicillin G sodium, phenobarbital sodium, pentobarbital sodium, and thiopental sodium. Do not mix with other drugs/diluents having parabens as preservatives. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None; *Darbazine*® is no longer available.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Prochlorperazine edisylate for Injection: 5 mg/mL in 2 mL and 10 mL vials; *Compazine*® (GlaxoSmithKline); generic; (Rx)

Prochlorperazine syrup: 1 mg/mL (as edisylate) in 120 mL; *Compazine*® (Glaxo-SmithKline); (Rx)

Prochlorperazine Tablets: 5 mg & 10 mg (as maleate); 10 mg & 15 mg (as maleate) sustained release capsules; *Compazine*® (SmithKlineBeecham); generic; (Rx)

Prochlorperazine (base) Suppositories: 2.5 mg, 5 mg, and 25 mg; *Compazine*® (GlaxoSmithKline); *Compro*® (Paddock); generic; (Rx)

PROMETHAZINE HCL

(proe-meth-a-zeen) Phenergan®

PHENOTHIAZINE

Prescriber Highlights

- Phenothiazine used as an antihistamine & antiemetic in small animals
- Relatively little experience with this drug in veterinary medicine; not frequently recommended for use
- Adverse Effects: sedation or anticholinergic effects

Uses/Indications

Promethazine may be useful in dogs and cats as an antiemetic. Because of its antihistamine actions, it has been tried for treating pruritus in atopic dogs, but its efficacy has been poor.

Pharmacology/Actions

The basic pharmacology of promethazine is similar to that of the other phenothiazines (refer to the acepromazine monograph for more information). It exhibits antiemetic, antihistaminic, anticholinergic, sedative, and local anesthetic actions.

Pharmacokinetics

Little information is available regarding the pharmacokinetics of promethazine in animals, although it probably follows the general patterns of other phenothiazine agents in absorption, distribution, and elimination.

In humans, the drug is well absorbed following oral or rectal administration, and via IM injection. Sedative effects occur within minutes of IV administration and persist for several hours. The drug is metabolized in the liver and these metabolites are eliminated primarily in the urine. Elimination half-life in humans is about 10 hours.

Contraindications/Precautions/Warnings

Animals may require lower dosages of general anesthetics following phenothiazines. Cautious use and smaller doses of phenothiazines should be given to animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of their hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia or shock. Do not use in patients with tetanus or strychnine intoxication due to effects on the extrapyramidal system. Use cautiously in very young or debilitated animals.

In humans, promethazine has a “black box warning” to not use the medication in children less than 2 years old; fatal respiratory depression has occurred in that patient group.

Adverse Effects

Little experience has been reported with this drug in animals, but prochlorperazine would most likely cause sedation or anticholinergic effects (dry mouth, etc.).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether promethazine is distributed into milk; a related compound, chlorpromazine has been detected in maternal milk. Although few cases are documented, a milk to plasma ratio of 0.5–0.7 or less is reported. Promethazine is unlikely to pose significant risk to nursing animals.

Overdosage/Acute Toxicity

Refer to the information listed in the acepromazine monograph. Acute extrapyramidal clinical signs (torticollis, tremor, salivation) have been successfully treated with injectable diphenhydramine in humans.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine or other phenothiazines and may be of significance in veterinary patients:

- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTI-DIARRHEAL MIXTURES** (e.g., **Kaolin/pectin, bismuth subsalicylate mixtures**): May cause reduced GI absorption of oral phenothiazines
- **ATROPINE & OTHER ANTICHOLINERGICS:** May have additive effects when used with promethazine
- **CNS DEPRESSANT AGENTS** (**barbiturates, narcotics, anesthetics**, etc.): May cause additive CNS depression if used with phenothiazines
- **EPINEPHRINE:** Phenothiazines block alpha-adrenergic receptors and concomitant epinephrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- **METOCLOPRAMIDE:** Phenothiazines may potentiate the extrapyramidal effects of metoclopramide
- **MONOAMINE OXIDASE INHIBITORS:** May potentiate extrapyramidal effects
- **OPIATES:** May enhance the hypotensive effects of the phenothiazines; dosages of prochlorperazine may need to be reduced when used with an opiate
- **ORGANOPHOSPHATE AGENTS:** Phenothiazines should not be given within one month of worming with these agents as their effects may be potentiated

Laboratory Considerations

- Promethazine can cause false positive results for **salicylates** in urine
- Promethazine can cause false positive or false negative results for **chorionic gonadotropin** in urine

Doses

■ DOGS/CATS:

As an antiemetic:

- a) 2 mg/kg PO or IM once daily (Dowling 2003a)

As an antihistamine:

- a) 0.2–0.4 mg/kg PO three to four times a day. (Morgan 2003)
- b) 0.2–0.4 mg/kg PO, IV, IM three to four times a day. (Bernard 1997)

Monitoring

- Efficacy

Client Information

- Dry mouth may be relieved by applying small amounts of water to animal's tongue for 10–15 minutes
- May cause sedation or behavior changes; contact veterinarian if these are a concern

- Protracted vomiting or diarrhea can be serious; contact veterinarian if clinical signs are not alleviated
- Contact veterinarian if animal exhibits abnormal movements or becomes rigid

Chemistry/Synonyms

Promethazine HCl occurs as a white to faint yellow, practically odorless, crystalline powder. It slowly oxidizes and acquires a blue color on prolonged exposure to air. Promethazine HCl is freely soluble in water, in hot dehydrated alcohol, and in chloroform, but practically insoluble in acetone, ether, or ethyl acetate. The pH of a 5% solution in water is between 4–5.

Promethazine may also be known as: Lilly 01516, PM 284, RP 3277, prometazina or *Phenergan*®. There are many other trade names available.

Storage/Stability/Compatibility

Store tablets at room temperature (20–25°C) in tight, light resistant containers. The syrup should be stored from 15–25°C and protected from light.

The injection should be stored at room temperature 20–25°C and protected from light. Keep in covered carton until time of use. Do not use if a precipitate forms or the solution is discolored. Promethazine can be adsorbed to plastic IV bags and tubing.

Promethazine suppositories should be stored in the refrigerator (2–8°C)

The following products have been reported to be physically **compatible** when promethazine injection is mixed with them: all usual IV fluids, amikacin, ascorbic acid, buprenorphine, butorphanol, cimetidine, diphenhydramine, fentanyl, fluconazole, glycopyrrolate, hydromorphone, hydroxyzine, meperidine, metoclopramide, midazolam, ondansetron, pancuronium, pentazocine, procainamide, and ranitidine.

Solutions of promethazine hydrochloride are **incompatible** with alkaline substances, which can precipitate promethazine base.

The following drugs have been reported to be physically **incompatible** when mixed with promethazine HCl: aminophylline, barbiturates, benzylpenicillin salts, carbenicillin sodium, chloramphenicol sodium succinate, chlorothiazide sodium, cefoperazone, dimenhydrinate, doxorubicin (in a liposomal formulation), furosemide, heparin sodium, hydrocortisone sodium succinate, morphine sulfate, and nalbuphine HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Promethazine HCl for Injection: 25 mg/mL in 1 mL amps & 50 mg/mL (For IM use only) in 1 mL amps; *Phenergan* (Wyeth); generic; (Rx)

Promethazine HCl syrup: 1.25 mg/mL in 473 mL; generic; (Rx)

Promethazine HCl Tablets: 12.5 mg, 25 mg & 50 mg; *Phenergan*® (Wyeth); generic; (Rx)

Promethazine HCl Suppositories: 12.5 mg, 25 mg, and 50 mg; *Phenergan*® (Wyeth), *Phenadoz*® (Paddock), generic; (Rx)

PROPANTHELINE BROMIDE

(proe-*pan*-the-leen) Pro-Banthine®

QUATERNARY ANTIMUSCARINIC

Prescriber Highlights

- ▶ Quaternary antimuscarinic agent used for its antispasmodic/antisecretory for treatment of diarrhea, hyperreflexic detrusor or urge incontinence & anticholinergic responsive bradycardias. In horses, IV to reduce colonic peristalsis & relax rectum to allow easier examination & surgery.
- ▶ Contraindications: Hypersensitivity to anticholinergics, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).
- ▶ Extreme Caution: Known or suspected GI infections, autonomic neuropathy. Caution: hepatic or renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, & geriatric or pediatric patients.
- ▶ Adverse Effects: Similar to atropine (dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation, etc.), but less effects on eye or CNS. Cats may exhibit vomiting & hypersalivation. High doses may cause ileus.

Uses/Indications

In small animal medicine propantheline bromide has been used for its antispasmodic/antisecretory effects in the treatment of diarrhea. It is also employed in the treatment of hyperreflexic detrusor or urge incontinence and as oral treatment in anticholinergic responsive bradycardias. In horses, propantheline has been used intravenously to reduce colonic peristalsis and for relaxing the rectum to allow easier rectal examination and surgery.

Pharmacology/Actions

An antimuscarinic with similar actions as atropine, propantheline is a quaternary ammonium compound and does not cross appreciably into the CNS. It should not exhibit the same extent of CNS adverse effects that atropine possesses. For further information, refer to the atropine monograph.

Pharmacokinetics

Quaternary anticholinergic agents are not completely absorbed after oral administration because they are completely ionized. In humans, peak levels occur about 2 hours after oral administration. Food apparently decreases the amount of drug absorbed. Propantheline is reportedly variably absorbed in dogs; dosages should be adjusted for each patient.

The distribution of propantheline has not been extensively studied, but like other quaternary antimuscarinics, propantheline is poorly lipid soluble and does not extensively penetrate into the CNS or eye.

Propantheline is believed to be prevalently metabolized in the GI and/or liver; less than 5% of an oral dose is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Use of propantheline should be considered contraindicated if the patient has a history of hypersensitivity to anticholinergic drugs, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).

Antimuscarinic agents should be used with extreme caution in patients with known or suspected GI infections. Propantheline or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Antimuscarinic agents should be used with caution in patients with hepatic disease, renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, and in geriatric or pediatric patients.

Adverse Effects

With the exception of fewer effects on the eye and the CNS, propantheline can be expected to have a similar adverse reaction profile as atropine (dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation, etc.). Vomiting and hypersalivation have also been reported in cats. High doses may lead to the development of ileus with resultant bacterial overgrowth in susceptible animals. For more information, refer to the atropine monograph.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Although anticholinergics (especially atropine) may be excreted in milk and can cause toxicity and reduce milk production, it is unknown if propantheline enters maternal milk. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Because of its quaternary structure, it would be expected that minimal CNS effects would occur after an overdose of propantheline when compared to atropine. See the information listed in the atropine monograph for more information on the clinical signs that may be seen following an overdose.

If a recent oral ingestion, emptying gut contents and administration of activated charcoal and saline cathartics may be warranted. Treat clinical signs supportively and symptomatically. Do not use phenothiazines as they may contribute to anticholinergic effects. Fluid therapy and standard treatments for shock may be instituted.

The use of physostigmine is controversial and should probably be reserved for cases where the patient exhibits either extreme agitation and is at risk for injuring themselves or others, or where supraventricular tachycardias and sinus tachycardias are severe or life threatening. The usual dose for physostigmine (human) is 2 mg IV slowly (for average sized adult); if no response may repeat every 20 minutes until reversal of toxic antimuscarinic effects or cholinergic effects takes place. The human pediatric dose is 0.02 mg/kg slow IV (repeat q10 minutes as above) and may be a reasonable choice for treatment of small animals. Physostigmine adverse effects (bronchoconstriction, bradycardia, seizures) may be treated with small doses of IV atropine.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propantheline and may be of significance in veterinary patients:

- **ANTIHISTAMINES:** May enhance the activity of propantheline
- **BENZODIAZEPINES:** May enhance the activity of propantheline
- **CIMETIDINE:** Propantheline may decrease the absorption of cimetidine
- **CORTICOSTEROIDS** (long-term use): May increase intraocular pressure
- **MEPERIDINE:** May enhance the activity of propantheline
- **NITRATES:** May potentiate the adverse effects of propantheline
- **NITROFURANTOIN:** Propantheline may enhance actions
- **PHENOTHIAZINES:** May enhance the activity of propantheline
- **SYMPATHOMIMETICS:** Propantheline may enhance actions
- **RANITIDINE:** Propantheline delays the absorption, but increases the peak serum level of ranitidine; the relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine
- **THIAZIDE DIURETICS:** Propantheline may enhance actions

Doses■ **DOGS:**

For detrusor hyperreflexia, urge incontinence:

- a) 0.2 mg/kg PO q6–8h; increase dose if necessary to the lowest dose that will control clinical signs (Polzin and Osborne 1985)
- b) 7.5–30 mg (total dose) PO once a day to q8h (Bartges 2003a)
- c) 7.5–15 mg (total dose) PO q12h; occasionally dosages of 30 mg q8h are required (Lane 2000)

For sinus bradycardia, incomplete AV block, etc.:

- a) 0.25–0.5 mg/kg PO q8–12h (Hogan 2004)
- b) 7.5–30 mg PO q8–12h; usually well tolerated, but improvement is usually partial and often temporary. (Rishniw and Thomas 2000)

For colitis, irritable bowel syndrome, etc.

- a) 0.25 mg/kg PO three times a day; do not use longer than 48–72 hours (48 hours for acute colitis) (DeNovo 1988)
- b) 0.5 mg/kg two to three times daily (Chiapella 1986)

As an antiemetic/antidiarrheal:

- a) 0.25 mg/kg PO q8h (DeNovo 1986)

■ **CATS:**

For detrusor hyperreflexia, urge incontinence:

- a) 0.25–0.5 mg/kg PO q12–24h. Empirical dosage. Further studies required to substantiate beneficial effect. (Osborne, Lulich et al. 2003b)
- b) 5–7.5 mg (total dose) PO once a day to once every 3 days (Lane 2000)
- c) 5–7.5 mg (total dose) PO q8h; 7.5 mg PO q72h (Bartges 2003a)

For sinus bradycardia, incomplete AV block, etc.:

- a) Although generally ineffective, a trial may be attempted using: 0.8–1.6 mg/kg three times daily (Harpster 1986)
- b) 7.5 mg PO q8–12h; usually well tolerated, but improvement is usually partial and often temporary (Rishniw and Thomas 2000)

For chronic colitis:

- a) 0.5 mg/kg two to three times daily (Chiapella 1986)

As an antiemetic/antidiarrheal:

- a) 0.25 mg/kg PO q8h (DeNovo 1986)

■ **HORSES:**

To reduce rectal contractions:

- a) During oocyte collection: 0.04 mg/kg IV (Carnevale and Coutinho da Silva 2003)
- b) 30 mg IV to inhibit peristalsis for 2 hours during rectal surgery (Merkt et al. 1979)

Note: There is no commercially available injectable product available in the U.S.A. Should a preparation be made from oral tablets, it should be freshly prepared and filtered through a 0.22 micron-filter before administering. Use with caution.

Monitoring

Dependent on reason for use:

- Clinical efficacy
- Heart rate and rhythm if indicated
- Adverse effects

Client Information

- Dry mouth may be relieved by applying small amounts of water to animal's tongue for 10–15 minutes.
- Protracted vomiting and diarrhea can be serious; contact veterinarian if symptoms are not alleviated.

Chemistry/Synonyms

A quaternary ammonium antimuscarinic agent, propantheline bromide occurs as bitter-tasting, odorless, white or practically white crystals, with a melting range of 156–162° (with decomposition). It is very soluble in both water and alcohol.

Propantheline bromide may also be known as: bromuro de propantelina, propanthelini bromidum, *Banthine*®, *Propantil*®, *Corrigast*®, *Ercorax Roll-on*®, *Ercoril*®, *Ercotina*®, *Pantheline*®, *Probamide*®, *Propantel*®, or *Propanthel*®.

Storage/Stability

Propantheline bromide tablets should be stored at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Propantheline Bromide Tablets: 7.5 mg & 15 mg; *Pro-Banthine*® (Schiapparelli Searle); generic; (Rx)

PROPIONIBACTERIUM ACNES INJECTION

(proe-pee-ohe-bak-ter-ee-um ak-nees)

Immunoregulin®, Eqstim®

IMMUNOSTIMULANT

Prescriber Highlights

- ▶ Immunostimulant for Staph pyoderma, FeLV, feline herpes, equine respiratory infections
- ▶ Contraindications: Hypersensitivity to compound, canine lymphoma, or leukemias with CNS involvement. Caution: Cardiac dysfunction
- ▶ Adverse Effects: Lethargy, hyperthermia, chills, & anorexia. Anaphylactic reactions are possible
- ▶ Extravasation may cause local tissue inflammation

Uses/Indications

The manufacturer's label notes the product (*Immunoregulin*®) "... indicated in the dog as adjunct to antibiotic therapy in the treatment of chronic recurring canine pyoderma to decrease the severity and extent of lesions and increase the percentage of dogs free of lesions after the appropriate therapeutic period." The equine product (*EqStim*®) is labeled as an immunostimulant for adjunctive therapy of primary or secondary viral or bacterial respiratory tract infections

Additionally, it has been used as an immunostimulant for the adjunctive treatment of feline rhinotracheitis and feline leukemia virus-induced disease. In dogs, it may be of use in the adjunctive treatment of oral melanoma and mastocytoma. Unfortunately, controlled studies documenting efficacy were not located for these potential indications.

Pharmacology/Actions

A non-specific immunostimulant, *Propionibacterium acnes* injection may induce macrophage activation, lymphokine production, increase natural killer cell activity, and enhance cell-mediated immunity.

Pharmacokinetics

No information was noted.

Contraindications/Precautions/Warnings

Propionibacterium acnes injection is contraindicated in patients hypersensitive to it. It should also be considered contraindicated in canine lymphoma or leukemias with CNS involvement. Use with caution in patients with cardiac dysfunction.

Adverse Effects

Occasionally within hours after injection, lethargy, increased body temperature, chills, and anorexia may be noted. Anaphylactic reactions have also been reported. Extravasation may cause local tissue inflammation. Long-term toxicity studies have demonstrated vomiting, anorexia, malaise, fever, acidosis, increased water consumption, and hepatitis.

Reproductive/Nursing Safety

Safe use during pregnancy has not been established.

Overdosage/Acute Toxicity

No overdosage information was noted; the manufacturer states that the antidote is epinephrine, presumably for the treatment of anaphylactic reactions.

Drug Interactions

The manufacturer states that the immunostimulant effects may be compromised if given concomitantly with **glucocorticoids** or **other immune suppressing drugs**; manufacturer recommends discontinuing steroids at least 7 days prior to initiating therapy.

Doses

■ DOGS:

For labeled indications (as adjunct to antibiotic therapy in the treatment of chronic recurring canine pyoderma):

- a) Shake well. Give via intravenous route at the following dosages: For animals weighing up to 15 lbs = 0.25–0.5 mL; 15–45 lbs = 0.25–1 mL; 45–75 lbs = 1–1.5 mL; >75 lbs = 1.5–2 mL. During the first two weeks, give 4 times at 3–4 day intervals, then once weekly until symptoms abate or stabilize. Maintenance doses once per month are recommended. (Package Insert; *Immunoregulin*®)
- b) For adjunctive therapy of chronic recurrent canine pyoderma: 0.03–0.07 mL/kg twice weekly for 10 weeks (combined with antibiotic therapy) (Barta 1992)

■ CATS:

For adjunctive therapy of feline retrovirus infections:

- a) 0.5 mL IV twice weekly for 2 weeks, then one injection weekly for 20 weeks or until cat is seronegative. (McCaw 1994)
- b) 0.25–0.5 mL IV twice weekly then every other week for 16 weeks (Levy 2004)
- c) As an antiviral immunostimulant in cats to increase hematopoiesis in FeLV-positive cats: 5 lb cats: 0.25 mL IV, IP twice weekly for 2 weeks, then once weekly until remission and once monthly after that to maintain clinical improvement. For 10 lb cats: 0.5 mL IV, IP twice weekly for 2 weeks, then once weekly for 3 weeks and once monthly for 2 months for a total of nine injections after that to maintain clinical improvement. Some protocols suggest follow-up with injections once weekly for 20 weeks or longer as needed. Others suggest follow-up with once weekly until clinical remission, and then once per month. (Greene, Hartmann et al. 2006)

■ HORSES:

As an immunostimulant for adjunctive therapy of primary or secondary viral or bacterial respiratory tract infections:

- a) Using *EqStim*®: 1 mL per 114kg (250 lb) body weight IV q48–72h (Flamino 2003)
- b) Using *EqStim*®: 1 mL per 114kg (250 lb) body weight IV. Repeat dosage on day 3 (or day 4), at day 7, and weekly as needed (Label information; *Eqstim*®—Neogen)

Monitoring

- Efficacy
- Adverse effects (see above)

Chemistry/Synonyms

Propionibacterium acnes injection is an immunostimulant agent, containing nonviable *Propionibacterium acnes* suspended in 12.5% ethanol in saline.

Propionibacterium acnes may also be known as: *Corynebacterium parvum*; NSC-220537, *Arthrokehlant A*®, *Coparvax*®, *Corymunun*®, *Eqstim*®, *Imunoparvum*®, and *Immunoregulin*®.

Storage/Stability

Store refrigerated; do not freeze. Shake well before using.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Propionibacterium acnes (non-viable) IV: 0.4 mg/mL in 5 mL and 50 mL vials; *Immunoregulin*® (Neogen); (OTC-biologic; manufacturer states that use is restricted to use by, or under the supervision of a veterinarian). Labeled for use in dogs. *Eqstim*® (Neogen). For use in horses and restricted to use by or under to the supervision of a veterinarian.

HUMAN-LABELED PRODUCTS: None

PROPOFOL

(*proe-po-fole*) Rapinivet®, PropoFlo®, Diprivan®

INJECTABLE ANESTHETIC**Prescriber Highlights**

- ▶ **Short-acting injectable hypnotic agent**
- ▶ **Contraindications:** Hypersensitivity to it or any component of the product
- ▶ **Caution:** Severe stress or having undergone trauma, hypoproteinemia, hyperlipidemia, seizures, or anaphylaxis history
- ▶ **Adverse Effects:** Transient respiratory depression is common but usually clinically tolerable. Apnea possible, especially if given too rapidly. May cause histamine release; anaphylactoid reactions possible. Hypotension, seizure-like clinical signs (paddling, opisthotonus, myoclonic twitching) during induction. Repeated doses in *Cats*: Increased Heinz body production, slowed recoveries, anorexia, lethargy, malaise, & diarrhea
- ▶ Little, if any, analgesia is provided
- ▶ Consider dose reduction if using other CNS depressant
- ▶ Sufficient monitoring & patient-support capabilities are mandatory
- ▶ Cats with preexisting liver disease may be susceptible to longer recovery times

Uses/Indications

In appropriate patients, propofol may be useful as an induction agent (especially before endotracheal intubation or an inhalant anesthetic), and as an anesthetic for outpatient diagnostic or minor procedures (e.g., laceration repair, radiologic procedures, minor dentistry, minor biopsies, endoscopy, etc.).

Propofol is used as a treatment for refractory status epilepticus, as it tends to cause less cardiovascular depression and recoveries can be smoother than with pentobarbital. Propofol may be of particular usefulness for use in Greyhounds and in patients with preexisting cardiac dysrhythmias. At low dosages, propofol is being investigated as an appetite stimulant in dogs.

Propofol may be safely used in animals with liver or renal disease and mild to moderate cardiac disease.

In dogs, propofol's labeled indications are: **1)** for induction of anesthesia; **2)** for maintenance of anesthesia for up to 20 minutes; **3)** for induction of general anesthesia where maintenance is provided by inhalant anesthetics.

Pharmacology/Actions

Propofol is a short acting hypnotic unrelated to other general anesthetic agents. Its mechanism of action is not well understood.

In dogs, propofol produces rapid yet smooth and excitement-free anesthesia induction (in 30–60 seconds) when given slowly IV. Sub-anesthetic dosages will produce sedation, restraint and an unawareness of surroundings. Anesthetic dosages produce unconsciousness and good muscle relaxation.

Propofol's cardiovascular effects include arterial hypotension, bradycardia, (especially in combination with opiate premedicants) and negative inotropism. It causes significant respiratory depression, particularly with rapid administration or very high dosages. Propofol also decreases intraocular pressure, increases appetite and has antiemetic properties. It does not appear to precipitate malignant hyperthermia and has little or no analgesic properties.

Pharmacokinetics

After IV administration, propofol rapidly crosses the blood brain barrier and has an onset of action usually within one minute. Duration of action after a single bolus lasts about 2–5 minutes. It is highly bound to plasma proteins (95–99%), crosses the placenta, is highly lipophilic, and reportedly enters maternal milk.

Propofol's short duration of action is principally due to its rapid redistribution from the CNS to other tissues. It is rapidly biotransformed in the liver via glucuronide conjugation to inactive metabolites, which are then excreted primarily by the kidneys. Because cats do not glucuronidate as well as dogs or humans, this may help explain their problems with consecutive day administration (see Adverse Effects below).

There is limited data available on propofol's pharmacokinetic parameters in dogs. The steady state volume of distribution is >3L/kg, elimination half-life about 1.4 hours, and clearance about 50 mL/kg/min.

Contraindications/Precautions/Warnings

Propofol is contraindicated in patients hypersensitive to it or any component of the product. It should not be used in patients where general anesthesia or sedation is contraindicated. Propofol should only be used in facilities where sufficient monitoring and patient-support capabilities are available.

Because patients that are in shock, under severe stress, or have undergone trauma may be overly sensitive to the cardiovascular and respiratory depressant effects of propofol, it should be used with caution in these patients. Adequate perfusion should be maintained before and during propofol anesthesia; dosage adjustments may be necessary.

Because propofol is so highly bound to plasma proteins, patients with hypoproteinemia may be susceptible to untoward effects; general anesthetic agents may be a safer choice in these patients.

The benefits of propofol should be weighed against its risks in patients with a history of hyperlipidemia, seizures or anaphylactic reactions. Cats with preexisting liver disease may be susceptible to longer recovery times.

Adverse Effects

Transient respiratory depression is common but is usually clinically tolerable. However, there is a relatively high incidence of apnea with resultant cyanosis if propofol is given too rapidly; it should be given slowly (25% of the calculated dose every 30 seconds until desired effect). Treat with assisted ventilation until spontaneous ventilation resumes.

Propofol has been documented to cause histamine release in some patients and anaphylactoid reactions (rare) have been noted in humans. Propofol has direct myocardial depressant properties and resultant arterial hypotension has been reported.

Occasionally, dogs may exhibit seizure-like clinical signs (padding, opisthotonus, myoclonic twitching) during induction, that, if persist, may be treated with intravenous diazepam. Propofol may have both anticonvulsant and seizure-causing properties. It should be used with caution in patients with a history of, or active seizure disorders, but some clinicians believe however, that propofol is actually more appropriate to use in seizure patients or in high seizure-risk procedures (e.g., myelography) than is thiopental.

While propofol is not inexpensive, it should ideally be used in a single-use fashion, as it is a good growth medium (contains no preservative) for bacteria.

When used in combination with other CNS depressant premedicants (e.g., acepromazine, narcotics, diazepam, etc.), a decrease in dosage of about 25% (from the single agent dose) should be considered. In very thin animals, consider dosage reduction as well.

When used repeatedly (once daily) in cats, increased Heinz body production, slowed recoveries, anorexia, lethargy, malaise, and diarrhea have been noted. Heinz body formation is due to oxidative injury to RBCs and has been documented in cats with other phenolic compounds as well. Consecutive use in dogs appears to be safe.

Pain upon injection has been reported in humans, but does not appear to be a clinically significant problem for dogs or cats. Extravasation of injection is not irritating nor does it cause tissue sloughing.

Propofol does not provide good analgesia, so appropriate analgesic agents should be used before and after painful procedures.

Reproductive/Nursing Safety

Propofol crosses the placenta and its safe use during pregnancy has not been established. High dosages (6X) in laboratory animals caused increased maternal death and decreased offspring survival rates after birth. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

In humans, propofol is not recommended for use in nursing mothers because propofol is excreted in maternal milk and the effects of oral absorption of small amounts of propofol are not known. Use with caution in nursing veterinary patients.

Overdosage/Acute Toxicity

Overdosages are likely to cause significant respiratory depression and, potentially, cardiovascular depression. Treatment should consist of propofol discontinuation, artificial ventilation with oxygen, and if necessary, symptomatic and supportive treatment for cardiovascular depression (e.g., intravenous fluids, pressors, anticholinergics, etc.).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propofol and may be of significance in veterinary patients:

- **ANESTHETICS, INHALATION (halothane, isoflurane):** Propofol serum concentrations may be increased
- **ANESTHETICS, LOCAL:** Propofol dosage requirements for sedation or hypnosis reduced

- **ANTICHOLINERGICS:** Propofol-induced bradycardia may be exacerbated in animals, particularly when opiate premedicants are used

- **CLONIDINE:** When used as a premed, may reduce propofol dosage requirements

- **CNS DEPRESSANTS:** Increased sedative, anesthetic, and cardiorespiratory depression possible

- **DRUGS THAT INHIBIT THE HEPATIC P-450 ENZYME SYSTEM (e.g., chloramphenicol, cimetidine, ketoconazole, etc.):** May potentially increase the recovery times associated with propofol; clinical significance is unclear, but it may be of significance in cats

- **FENTANYL:** In pediatric (human) patients increased risk for bradycardia

- **MEDETOMIDINE:** When propofol is used after medetomidine, hypoxemia may occur; dosage adjustments may be required along with adequate monitoring

- **MIDAZOLAM:** May have synergistic effects with propofol, midazolam plasma concentrations may be increased up to 20%

- **OPIATES:** May increase the serum concentrations of both the opiate and propofol if used together

Doses

■ DOGS & CATS:

Note: The Rapinover® (Schering-Plough) package insert has very detailed dosing recommendations for both induction and maintenance of general anesthesia with propofol, including dosage adjustments when acepromazine, xylazine, butorphanol, oxymorphone or medetomidine premedication is used.

As an anesthetic:

a) As a single injection (25% of the calculated dose every 30 seconds until desired effect):

For healthy, unpremedicated animal: 6 mg/kg IV;

For healthy, premedicated animal: After tranquilizer (e.g., acepromazine) = 4 mg/kg IV; after sedative (e.g., xylazine, opioids) = 3 mg/kg IV.

As a constant infusion:

For sedation only: 0.1 mg/kg/minute;

For minor surgery: 0.6 mg/kg/min, or 1 mL (10 mg) per minute per 12–25 kg of body weight (Robinson, Sanderson et al. 1993)

b) Dogs: For induction without premedication: 5–6 mg/kg IV; With acepromazine (0.05 mg/kg IM, IV, or SC), propofol given at 3–4 mg/kg IV;

With acepromazine and oxymorphone (0.09 mg/kg IM, IV or SC), propofol given at 2.3 mg/kg IV. Xylazine or medetomidine premeds may reduce propofol dose further.

Cats: Premed with acepromazine (0.05–1 mg/kg IM) with or without an analgesic such as butorphanol (0.2–0.4 mg/kg IM) and induce with propofol at 4–6 mg/kg IV. Doses of propofol at 8–13 mg/kg IV will allow intubation without topical anesthesia, lower propofol dose if topical anesthesia is used. (Mathews 1999)

c) 6 mg/kg IV; in healthy animals 25% of the calculated dose is administered every 30 seconds until intubation is possible. After induction, duration of anesthesia is only 2.5–9.4 minutes. Maintenance anesthesia obtained using either inhalational agents or a continuous infusion of propofol at approximately 0.4 mg/kg/minute. If anesthesia appears inadequate, a small bolus of 1 mg/kg followed by an increase in the infusion rate by 25%. If infusion is too deep, discontinue infusion until suitable anesthesia level is achieved. An infu-

sion dose of 0.1 mg/kg/min appears to be suitable dose for sedation in the dog. (Ilkiw 1992)

- d) As an induction agent for halothane or isoflurane anesthesia: 6.6 mg/kg IV given over 60 seconds to unpremedicated dogs. Best achieved by early intubation and administration of the inhalant following propofol induction. (Bufalari, Miller et al. 1998)

For refractory status epilepticus:

- a) Using IV bolus or constant rate IV infusion: 0.1–0.6 mg/kg/minute. Use only in settings where definitive airway control and hemodynamic support can occur. (Platt and McDonnell 2000)
- b) If seizures persist after diazepam and phenobarbital therapy: 3–6 mg/kg IV followed by an infusion of 8–12 mg/kg/hour. Must closely monitor for hypoventilation and may require mechanical ventilatory support. (Munana 2004b)
- c) If seizures persist after diazepam and phenobarbital therapy in dogs: Propofol IV bolus at 1–3.5 mg/kg up to 6 mg/kg followed by a CRI using a syringe pump of 0.1–0.25 mg/kg/minute (up to 0.6 mg/kg/minute) for 6–12 hours and then gradually decreased; maximum duration of propofol CRI is approximately 48 hours. If used in cats, carefully monitor PVC and CBC (Heinz body anemia, hemolytic anemia) and propofol dose should be kept as low, and duration of treatment as short, as possible. (Knipe 2006b)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 5–14 mg/kg slow IV (20 mg/kg/minute) to effect; not recommended as the sole agent for maintenance (Ivey and Morrissey 2000)
- b) Mice: 26 mg/kg IV. Rats: 10 mg/kg IV (Adamcak and Otten 2000)

■ REPTILES:

- a) Iguanas: 3 mg/kg IV via either intraosseous catheter or into the coccygeal or ventral abdominal vein. Wait 3–5 minutes before giving additional increments. May also be used in tortoises. (Heard 1999)
- b) 5–15 mg/kg IV or IO; in snakes intracardiac route is usually used (Innis 2003)

Monitoring

- Level of anesthesia/CNS effects
- Respiratory depression
- Cardiovascular status (cardiac rate/rhythm; blood pressure)

Chemistry/Synonyms

Propofol is an alkylphenol derivative (2,6-diisopropylphenol). The commercially available injection is an emulsion containing 100 mg/mL of soybean oil, 22.5 mg/mL of glycerol, and 12 mg/mL of egg lecithin. The emulsion has a pH of 7–8.5. Propofol may also be known as disoprofol.

Propofol may also be known as: disoprofol, ICI-35868, propofol, *Ansiven*®, *Bioprofol*®, *Cryotol*®, *Dipropofol*®, *Diprivan*®, *Disoprivan*®, *Fresofol*®, *Ivofol*®, *Klimofol*®, *Oleo-Lax*®, *Pofol*®, *Profolen*®, *Pronest*®, *Propoabbott*®, *Propocam*®, *PropoFlo*®, *Propovan*®, *Provive*®, *Rapinovel*®, *Recofol*®, or *Recofol*®.

Storage/Stability/Compatibility

Store propofol injection below 22°C (72°F), but not below 4°C (40°F); do not refrigerate or freeze. Protect from light. Shake well before using. Do not use if the emulsion has separated. The manufacturer recommends discarding any unused portion at the end of the anesthetic procedure or after 6 hours, whichever occurs sooner.

Propofol is physically **compatible** with the commonly used IV solutions (e.g., LRS, D5W) when injected into a running IV line. Drugs that are reported to be **compatible** with Y-site administration include (partial listing): ampicillin, butorphanol, calcium gluconate, cefazolin, cefoxitin, clindamycin, dexamethasone sodium phosphate, dexmetomidine, diphenhydramine, dobutamine, dopamine, epinephrine, fentanyl, furosemide, heparin sodium, insulin, ketamine, lorazepam, magnesium sulfate, mannitol, naloxone, pentobarbital, phenobarbital, potassium chloride, propranolol, sodium bicarbonate, succinylcholine, thiopental, and vecuronium. It is **incompatible** with atracurium and vecuronium. Refer to specialized references or a hospital pharmacist for more information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Propofol Injectable: 10 mg/mL in 5 mL and 20 mL (single use) vials; *Rapinovel*® (Schering Plough); *PropoFlo*® (Abbott); (Rx). Approved for use in dogs and cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Propofol Injection, Emulsion: 10 mg/mL in 20 mL amps & vials, 50 mL and 100 mL infusion vials and 50 mL prefilled single-use syringes; *Diprivan*® (AstraZeneca); Propofol (Baxter); (Rx)

PROPRANOLOL HCL

(proe-pran-oh-lole) Inderal®

BETA-ADRENERGIC BLOCKER

Prescriber Highlights

- Non specific beta blocker primarily used in veterinary medicine as an antiarrhythmic agent
- Contraindications: Heart failure, hypersensitivity to this class of agents, greater than 1st degree heart block, or sinus bradycardia; generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blockers or with bronchospastic lung disease
- Caution: Significant renal or hepatic insufficiency, sinus node dysfunction, labile diabetic patients, digitalized or digitalis intoxicated patients
- Adverse Effects: Bradycardia, lethargy, & depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, syncope, diarrhea, hypoglycemia, & bronchoconstriction
- May mask (treat) clinical signs of thyrotoxicosis
- If discontinuing drug, consider gradual withdrawal
- Drug Interactions

Uses/Indications

While propranolol is used for hypertension, migraine headache prophylaxis, and angina in human patients, it is used primarily in veterinary medicine for its antiarrhythmic effects. Dysrhythmias treated with propranolol include: atrial premature complexes, ventricular premature complexes, supraventricular premature complexes and tachyarrhythmias, ventricular or atrial tachyarrhythmias secondary to digitalis, atrial tachycardia secondary to Wolff-Parkinson-White

(WPW) with normal QRS complexes, and atrial fibrillation (generally in combination with digoxin). Propranolol reportedly improves cardiac performance in animals with hypertrophic cardiomyopathy. It has been used to treat systemic hypertension and clinical signs associated with thyrotoxicosis and pheochromocytoma.

Pharmacology/Actions

Propranolol blocks both β_1 - and β_2 -adrenergic receptors in the myocardium, bronchi, and vascular smooth muscle. Propranolol does not have any intrinsic sympathomimetic activity (ISA). Additionally, propranolol possesses membrane-stabilizing effects (quinidine-like) affecting the cardiac action potential and direct myocardial depressant effects. Cardiovascular effects secondary to propranolol include: decreased sinus heart rate, depressed AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, decreased hepatic and renal blood flow, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia. Electrophysiologic effects on the heart include decreased automaticity, increased or no effect on effective refractory period, and no effect on conduction velocity.

Additional pharmacologic effects of propranolol, include increased airway resistance (especially in patients with bronchoconstrictive disease), prevention of migraine headaches, increased uterine activity (more so in the non-pregnant uterus), decreased platelet aggregability, inhibited glycogenolysis in cardiac and skeletal muscle, and increased numbers of circulating eosinophils.

Pharmacokinetics

Propranolol is well absorbed after oral administration, but a rapid first-pass effect through the liver reduces systemic bioavailability to approximately 2–27% in dogs, thereby explaining the significant difference between oral and intravenous dosages. These values reportedly increase with chronic dosing. Hyperthyroid cats may have increased bioavailability of propranolol when compared with normal cats.

Propranolol is highly lipid soluble and readily crosses the blood-brain barrier. The apparent volume of distribution has been reported to 3.3–11 L/kg in the dog. Propranolol crosses the placenta and enters milk (at very low levels). In humans, propranolol is approximately 90% bound to plasma proteins.

Propranolol metabolism occurs principally by the liver. An active metabolite, 4-hydroxypropranolol, has been identified after oral administration in humans. Less than 1% of a dose is excreted unchanged into the urine. The half-life in dogs has been reported to range from 0.77–2 hours, and in horses, less than 2 hours. It has been reported that hyperthyroid cats have a decreased clearance of propranolol when compared with normal cats.

Contraindications/Precautions/Warnings

Propranolol is contraindicated in patients with overt heart failure, hypersensitivity to this class of agents, greater than 1st degree heart block, or sinus bradycardia. Non-specific β -blockers are generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to β -blocker therapy. They are also relatively contraindicated in patients with bronchospastic lung disease.

Propranolol should be used cautiously in patients with significant renal or hepatic insufficiency, or with sinus node dysfunction.

Propranolol can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients.

Propranolol can mask the clinical signs associated with thyrotoxicosis, but it has been used clinically to treat the clinical signs associated with this condition.

Use propranolol cautiously with digitalis or in digitalis intoxicated patients; severe bradycardias may result.

Adverse Effects

It is reported that adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Clinically relevant adverse effects include: bradycardia, lethargy and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction. Syncope and diarrhea have also been reported in canine patients.

Exacerbations of clinical signs have been reported following abrupt cessation of β -blockers in humans. It is recommended to withdraw therapy gradually in patients who have been receiving the drug chronically.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Propranolol is excreted in maternal milk. Use with caution in nursing patients.

Overdosage/Acute Toxicity

The most predominant clinical signs expected would be hypotension and bradycardia. Other possible effects could include: CNS (depressed consciousness to seizures), bronchospasm, hypoglycemia, hyperkalemia, respiratory depression, pulmonary edema, other arrhythmias (especially AV block), or asystole.

There were 94 exposures to propranolol HCl reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 86 were dogs with 4 showing clinical signs and 8 cats with 2 showing clinical signs. Common findings in dogs recorded in decreasing frequency included bradycardia, hypotension, collapse and depression. Common findings in cats recorded in decreasing frequency included bradycardia.

If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered but use caution since coma and seizures may develop rapidly. Monitor patient's ECG, blood glucose, potassium and, if possible, blood pressure; treatment of the cardiovascular and CNS effects are symptomatic. Use fluids and pressor agents to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol given cautiously has been recommended. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with digoxin, diuretics, oxygen and, if necessary, IV aminophylline. Glucagon (5–10 mg IV; human dose) may increase heart rate and blood pressure and reduce the cardiodepressant effects of propranolol. Seizures generally will respond to IV diazepam.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propranolol and may be of significance in veterinary patients:

- **ANTACIDS:** May reduce oral propranolol absorption; separate doses by at least one hour
- **ANESTHETICS, GENERAL:** Additive myocardial depression may occur with the concurrent use of propranolol and myocardial depressant anesthetic agents

- **ANTICHOLINERGICS:** May negate cardiac effects of beta-blockers
- **CALCIUM CHANNEL BLOCKERS:** Concurrent use of beta-blockers with calcium channel blockers (or other negative inotropes) should be done with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **CIMETIDINE:** May decrease the metabolism of propranolol and increase blood levels
- **DIURETICS:** May increase risk for hypotension
- **EPINEPHRINE:** Unopposed alpha effects of epinephrine may lead to rapid increases in blood pressure and decrease in heart rate
- **FLUOXETINE:** May decrease propranolol metabolism; complete heart block reported in one human
- **INSULIN and other ANTIDIABETIC DRUGS:** Propranolol may prolong the hypoglycemic effects of insulin therapy
- **LIDOCAINE:** Clearance may be impaired by propranolol
- **METHIMAZOLE, PROPYLTHIOURACIL:** Propranolol doses may need to be decreased when initiating therapy
- **PHENOTHIAZINES:** May increase risk for hypotension
- **RESERPINE:** May have additive effects with propranolol
- **SUCCINYLCHOLINE, TUBOCURARINE:** Effects may be enhanced with propranolol therapy
- **SYMPATHOMIMETICS (metaproterenol, terbutaline, beta effects of epinephrine, phenylpropanolamine, etc.):** May have their actions blocked by propranolol
- **THEOPHYLLINE:** Effects of theophylline (bronchodilation) may be blocked by propranolol
- **THYROID HORMONES:** May decrease the effects of beta blocking agents

Doses

- **DOGS:**
 - a) For susceptible cardiac arrhythmias: 0.02 mg/kg IV slowly (up to a maximum of 1 mg/kg). Oral dose: 0.1–0.2 mg/kg initially PO q8h, up to a maximum of 1.5 mg/kg q8h (Ware 2000)
 - b) As a beta-blocker for adjunctive therapy in heart failure: 0.1–0.2 mg/kg PO q8h (start low and titrate) (Fox 2003a)
 - c) For loud-noise phobias: 5–40 mg/dog q8h (Crowell-Davis 1999)
- **CATS:**
 - a) For susceptible cardiac arrhythmias: 0.02 mg/kg IV slowly (up to a maximum of 1 mg/kg). Oral dose: 2.5 mg (up to 10 mg) total dose per cat q 8–12h (Ware 2000)
 - b) For susceptible cardiac arrhythmias: 0.02 mg/kg IV over one minute; can repeat up to a maximum of four times as needed based upon response (Cote 2004)
 - c) As a beta-blocker for adjunctive therapy in heart failure: 2.5–10 mg (total dose) PO q8h (start low and titrate) (Fox 2003a)
 - d) For adjunctive therapy of hypertension: 2.5–5 mg (total dose) PO q8–12h (Sparkes 2003b)
 - e) For adjunctive therapy (to control neuromuscular and cardiovascular effects) in feline hyperthyroidism: 2 mg/kg (6.25 mg per cat) once daily (Behrend 1999)
 - f) For loud-noise phobias: 0.25 mg/kg as needed (Crowell-Davis 1999)
- **FERRETS:**
 - For hypertrophic cardiomyopathy: 0.5–2 mg/kg PO or SC once a day to twice a day (Williams 2000)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- a) For V-Tach: 0.05–0.16 mg/kg IV. **Note:** negative inotropic and chronotropic effects may be undesirable. (Mogg 1999)
- b) For V-Tach: 0.03–0.15 mg/kg IV or 0.3–0.7 mg/kg PO q8h. Considered not as effective as lidocaine; decreases ventricular rate even if it does not restore sinus rhythm. Toxic effects include bradycardia, AV block, proarrhythmic, negative inotrope and hypotension. Use with caution in animals with airway disease (bronchoconstriction). (Kimberly and McGur-rin 2006)
- c) Oral: Days 1 and 2: 175 mg three times a day; Days 3 and 4: 275 mg three times a day; Days 5 and 6: 350 mg three times daily.
Intravenous: Days 1 and 2: 25 mg two times a day; Days 3 and 4: 50 mg two times a day; Days 5 and 6: 75 mg twice daily (Hilwig 1987)

Monitoring

- ECG
- Toxicity (see Adverse Effects/Overdosage)
- Blood pressure if administering IV

Client Information

- To be effective, the animal must receive all doses as prescribed.
- Notify veterinarian if animal becomes lethargic or becomes exercise intolerant, begins wheezing, develops shortness of breath or cough, or presents a change in behavior or attitude.

Chemistry/Synonyms

A non-specific beta-adrenergic blocking agent, propranolol HCl occurs as a bitter tasting, odorless, white to almost white powder with a pK_a of 9.45 and a melting point of about 161°C. One gram of propranolol is soluble in about 20 mL of water or alcohol. At a pH from 4–5, solutions of propranolol will fluoresce. The commercially available injectable solutions are adjusted with citric acid to a pH 2.8–3.5.

Propranolol may also be known as: AY-64043, ICI-45520, NSC-91523, propranololi hydrochloridum; many trade names are available.

Storage/Stability/Compatibility

All propranolol preparations should be stored at room temperature (15–30°C) and protected from light. Propranolol solutions will decompose rapidly at alkaline pH. Propranolol injection is reported to be physically **compatible** with D₅W, 0.9% sodium chloride, or lactated Ringer's injection. It is also physically **compatible** with dobutamine HCl, verapamil HCl, and benzquinamide HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Propranolol HCl Tablets: 10 mg, 20 mg, 40 mg, 60 mg, 80 mg & 90 mg; *Inderal*® (Wyeth-Ayerst); generic; (Rx)

Propranolol HCl Extended/Sustained-Release Capsules: 60 mg, 80 mg, 120 mg & 160 mg; *Inderal*® LA (Wyeth-Ayerst); *InnoPran*® XL (Reliant); generic; (Rx)

Propranolol for Injection: 1 mg/mL in 1 mL amps or vials; *Inderal*® (Wyeth-Ayerst); generic; (Rx)

Propranolol Oral Solution: 4 mg/mL & 8 mg/mL in 500 mL and UD5 mL patient cups, and 80 mg/mL concentrate in 30 mL; *Propranolol Intenso*® and *Propranolol HCl*® (Roxane); (Rx)

In addition, fixed dose combination products containing propranolol and hydrochlorothiazide are available to treat hypertension in humans.

Prostaglandin F₂ alpha—see **Dinoprost Tromethamine**

PROTAMINE SULFATE

(*proe-ta-meen*)

ANTIDOTE (HEPARIN)

Prescriber Highlights

- ▶ Protein that complexes with heparin (treatment of overdoses); may also be useful for Bracken Fern poisoning
- ▶ Contraindications: Hypersensitivity to protamine
- ▶ Adverse Effects: If injected IV too rapidly: Acute hypotension, bradycardia, pulmonary hypertension, & dyspnea; hypersensitivity possible
- ▶ Monitor for heparin “rebound effect”

Uses/Indications

Protamine is used in all species for the treatment of heparin overdose when significant bleeding occurs. While protamine will neutralize the anti-thrombin effects of low molecular weight heparins (e.g., dalteparin or enoxaparin), it does not completely inhibit their anti-Xa activity. Laboratory animal studies however, shows it does improve microvascular bleeding associated with LMWH overdoses. Protamine has been suggested for use for Bracken Fern toxicity in ruminants (see Doses).

Pharmacology/Actions

Protamine is strongly basic and heparin, strongly acidic; protamine complexes with heparin to form an inactive stable salt. Protamine has intrinsic anticoagulant activity, but its effects are weak and rarely cause problems.

Pharmacokinetics

After IV injection, protamine binds to heparin within 5 minutes. The exact metabolic fate of the heparin-protamine complex is not known, but there is evidence that the complex is partially metabolized and/or degraded by fibrinolysin thus freeing heparin.

Contraindications/Precautions/Warnings

Protamine is contraindicated in patients who have demonstrated hypersensitivity or intolerance to the drug in the past.

Adverse Effects

If protamine sulfate is injected IV too rapidly, acute hypotension, bradycardia, pulmonary hypertension, and dyspnea can occur. These effects are usually absent or minimized when the drug is administered slowly (over 1–3 minutes). Hypersensitivity reactions have also been reported.

A heparin “rebound” effect has been reported where anticoagulation and bleeding occur several hours after heparin has apparently been neutralized. This may be due to either a release of heparin from extravascular compartments or the release of heparin from the protamine-heparin complex.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in maternal milk.

Overdosage/Acute Toxicity

Because protamine has inherent anticoagulant activity, overdoses of protamine may, theoretically, result in hemorrhage; however, in one human study, overdoses of 600–800 mg resulted only in mild, transient effects on coagulation. The LD₅₀ of protamine in mice is 100 mg/kg.

Drug Interactions; Laboratory Considerations

None were located.

Doses

■ **DOGS & CATS** (and presumably other species):

For heparin overdose:

- a) Give 1–1.5 mg protamine sulfate to antagonize each mg (≈100 units) of heparin via slow IV injection. Reduce dose as time increases between heparin dose and start of treatment (after 30 minutes give only 0.5 mg). (Bailey 1986a)
- b) Administer 1 mg protamine for each 100 Units of heparin to be inactivated. Decrease protamine dose by 1/2 for every 30 minutes that have lapsed since heparin was administered (*Plumb's Note:* This may be ineffective if heparin has been administered by deep SC injection). Give dose slowly IV, do not give at a rate faster than 50 mg over a 10-minute period. (Adams 1988b)

■ **CATTLE:**

For Bracken Fern (*Pteridium* spp.) poisoning:

- a) In combination with whole blood (2.25–4.5L), 1 injection of 10 mL of 1% protamine sulfate IV (Osweiler and Ruhr 1986)

Monitoring

■ See the Heparin monograph

Client Information

■ Should only be used in a setting where adequate monitoring facilities are available.

Chemistry/Synonyms

Simple, low molecular weight, cationic proteins, protamines occur naturally in the sperm of fish. Commercially available protamine sulfate is produced from protamine obtained from the sperm or mature testes of salmon (or related species). It occurs as a fine, white to off-white crystalline or amorphous powder that is sparingly soluble in water and very slightly soluble in alcohol. The injection is available as either a prepared solution with a pH of 6–7 or a lyophilized powder that has a pH of 6.5–7.5 after reconstituting.

Protamine Sulfate may also be known as: protamine sulphate, protamini sulfas, sulfato de protamina, *Prosulf*®, or *Prota*®.

Storage/Stability/Compatibility

The powder for injection should be stored at room temperature (15–30°C), and the injection (liquid) in the refrigerator (2–8°C); avoid freezing. The injection is stable at room temperature for at least 2 weeks, however. The powder for injection should be used immediately if reconstituted with Sterile Water for Injection and within 72 hours if reconstituted with Bacteriostatic Water for Injection.

It is recommended to use either D5W or normal saline for protamine sulfate infusions. Cimetidine and verapamil are reported to be physically **compatible** with protamine sulfate for injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Protamine Sulfate Injection: 10 mg/mL preservative-free in 5 mL and 25 mL vials; generic; (Rx)

PSEUDOEPHEDRINE HCL

(soo-doe-e-fed-rin) Equiped®, Sudafed®

SYMPATHOMIMETIC

Prescriber Highlights

- ▶ Oral sympathomimetic used primarily for urethral sphincter hypotonus when phenylpropanolamine unavailable
- ▶ **Caution:** Glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension
- ▶ **Adverse Effects:** Restlessness, irritability, hypertension, & anorexia
- ▶ **Restricted drug in USA;** can be used as a precursor to manufacture methamphetamine

Uses/Indications

Pseudoephedrine is used primarily as a substitute for phenylpropanolamine for the treatment of urinary incontinence (dribbling) in dogs. It may also be used as an oral decongestant.

Pharmacology/Actions

While the exact mechanisms of pseudoephedrine's actions are undetermined, it is believed that it indirectly stimulates both alpha- and beta- (to a lesser degree) adrenergic receptors by causing the release of norepinephrine.

Pharmacologic effects of pseudoephedrine include increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased nasal congestion and appetite. Pseudoephedrine can also increase urethral sphincter tone and produce closure of the bladder neck.

Pharmacokinetics

Pseudoephedrine is rapidly and nearly completely absorbed from the GI tract. Food may delay the absorption somewhat, but not the extent. In children, the apparent volume of distribution is about 2.5 L/kg. Pseudoephedrine is only partially metabolized and the bulk is excreted unchanged in the urine. Urine pH can affect excretion rates. Alkaline urine (pH 8) can prolong half-life while acidic urine (pH 5) can decrease it.

Contraindications/Precautions/Warnings

Pseudoephedrine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders or hypertension.

Adverse Effects

Adverse effects are dose related and adrenergic in nature with CNS excitement/restlessness/insomnia, and rapid heart rate the most likely to be seen at usual doses. Decreased appetite is possible.

Increases in blood pressure and arrhythmias are possible in susceptible individuals, particularly at high doses.

Because pseudoephedrine may be used to manufacture methamphetamine, be alert for clients wanting to purchase very large amounts of the drug.

Reproductive/Nursing Safety

Safe use has not been established during pregnancy; use with care. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

In humans, it is not recommended to use systemic pseudoephedrine during breastfeeding as the drug enters maternal milk and infants may be very susceptible to the drug's effects. Use with caution in veterinary patients.

Overdosage/Acute Toxicity

Overdoses of pseudoephedrine can cause hyperthermia, mydriasis, tachycardia, vomiting, disorientation, and seizures. In small animals, adverse reactions may develop at doses of 5–6 mg/kg. Deaths have occurred at doses of 10–12 mg/kg.

There were 53 exposures to pseudoephedrine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases all 53 were dogs with 6 showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, vomiting, tremors, seizures and blindness.

Large overdoses should be treated with gastric evacuation (if not contraindicated); otherwise, treat supportively and symptomatically (e.g., propranolol for tachycardia, diazepam for seizures). Phenothiazines are preferred to treat hyperactivity, agitation, and tremors as diazepam may worsen dysphoria. It is recommended to contact an animal poison control center for further guidance in the case of a large pseudoephedrine overdose.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pseudoephedrine and may be of significance in veterinary patients:

- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly selegiline): Pseudoephedrine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors
- **RESERPINE:** An increased chance of hypertension if given concomitantly
- **SYMPATHOMIMETIC AGENTS, OTHER:** Phenylpropanolamine should not be administered with other sympathomimetic agents (e.g., ephedrine) as increased toxicity may result
- **TRICYCLIC ANTIDEPRESSANTS** (clomipramine, amitriptyline, etc.): An increased chance of hypertension if given concomitantly

Doses

■ DOGS:

- a) For urinary incontinence, or as a decongestant: 0.2–0.4 mg/kg (or practically, 15–60 mg total dose per dog) PO q8–12h (Tilley and Smith 2000)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- a) For use when an antihistamine/decongestant may be useful using the pyrilamine/pseudoephedrine oral granules: 1/2 ounce (1 tablespoonful) per 1,000 lb body weight. May mix with feed and repeated at 12 hr intervals if needed. Do not use at least 72 hours before sporting events. (Label information—veterinary products listed below)

Monitoring

- Efficacy
- Adverse effects (heart rate, CNS stimulation, appetite)

Client Information

- For this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.
- Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

Chemistry/Synonyms

A sympathomimetic, pseudoephedrine HCl is the stereoisomer of ephedrine. It occurs as a fine, white to off-white powder or crystals. Approximately 2 grams are soluble in one mL of water.

Pseudoephedrine may also be known as: pseudoephedrini, pseudoephedrina, *Equi-Phar Equi-Hist 1200 Granules*®, *Drixoral*®, *Equiphed*®, *Histgranules*®, *Sudafed*®, and *Tri-Hist*®.

Storage/Stability

Oral pseudoephedrine products should be stored at room temperature in tight containers. Oral liquid preparations should be protected from light and freezing.

Dosage Forms/Regulatory Status

In the USA, pseudoephedrine is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

VETERINARY-LABELED PRODUCTS:

Pseudoephedrine HCl 600 mg/oz and Pyrilamine maleate 600 mg/oz Granules in 20 oz, 5 lb and 10 lb containers; *Equiphed*® (AHC), *Equi-Phar Equi-Hist 1200 Granules*® (Vedco); *Tri-Hist*® Granules (Neogen); *Histgranules*® (Butler); (Rx). Approved for use in horses not intended for food. Do not use at least 72 hours before sporting events.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pseudoephedrine HCl Tablets and Capsules: 15 mg (chewable), 30 mg (regular & softgel), and 60 mg; 120 mg and 250 mg extended/controlled-release. A common trade name is *Sudafed*®, but there are many others and generically labeled pseudoephedrine is available. All are OTC, but sales are now restricted to “behind-the-counter” status.

Pseudonephedrine Sulfate Tables (Extended-Release): 120 mg; *Drixoral 12 Hour Non-Drowsy Formula*® (Schering-Plough Healthcare); (OTC, restricted)

Pseudoephedrine Liquid: 3 mg/mL and 6 mg/mL in 118 mL, 120 mL, 237 mL, 480 mL and 3.8 L. A common trade name is *Sudafed*®, but there are many others, including generically labeled pseudoephedrine available. All are OTC, restricted.

Pseudoephedrine Oral Drops: 7.5 mg/0.8 mL in 15 mL and 30 mL; (OTC, restricted)

PSYLLIUM HYDROPHILIC MUCILLOID

(sill-i-yum hye-droe-fill-ik myoo-sill-oid)

Metamucil®, Equi-Psyllium®

BULK FORMING GI LAXATIVE/ANTIDIARRHEAL

Prescriber Highlights

- Bulk-forming agent used for treatment & prevention of sand colic in horses, as a laxative, & to increase stool consistency in patients with chronic, watery diarrhea
- **Contraindications:** Rabbits. Where prompt intestinal evacuation is required, & when fecal impaction or intestinal obstruction is present.
- **Adverse Effects:** Flatulence; if insufficient liquid is given, increased possibility of esophageal or bowel obstruction

Uses/Indications

Bulk forming laxatives are used in patients where constipation is a result a too little fiber in their diets or when straining to defecate may be deleterious. Psyllium is considered the laxative of choice in the treatment and prevention of sand colic in horses.

Psyllium has also been used to increase stool consistency in patients with chronic, watery diarrhea. The total amount of water in the stool remains unchanged.

Pharmacology/Actions

By swelling after absorbing water, psyllium increases bulk in the intestine and is believed to induce peristalsis and decrease intestinal transit time. In the treatment of sand colic in horses, psyllium is thought to help collect sand and to help lubricate its passage through the GI tract.

Pharmacokinetics

Psyllium is not absorbed when administered orally. Laxative action may take up to 72 hours to occur.

Contraindications/Precautions/Warnings

Bulk-forming laxatives should not be used in cases where prompt intestinal evacuation is required, or when fecal impaction (no feces being passed) or intestinal obstruction is present. Psyllium products are not recommended for use in rabbits as they may damage intestinal mucosa and cause blockage.

Adverse Effects

With the exception of increased flatulence, psyllium very rarely produces any adverse reactions if adequate water is given or is available to the patient. If insufficient liquid is given, there is an increased possibility of esophageal or bowel obstruction occurring.

Reproductive/Nursing Safety

Because there is no appreciable absorption of psyllium from the gut, it should be safe to use in pregnant animals. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Psyllium should be safe to administer to lactating animals.

Overdosage/Acute Toxicity

If administered with sufficient liquid, psyllium overdose should cause only an increased amount of soft or loose stools.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving psyllium and may be of significance in veterinary patients:

- **ASPIRIN** (and other **SALICYLATES**): Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more
- **DIGOXIN**: Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more
- **NITROFURANTOIN**: Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more

Doses■ **DOGS:**

- a) For a trial to treat chronic idiopathic large bowel diarrhea using *Metamucil*®: Median dose is 2 tablespoonsful (1.33 g/kg/day; range: 0.32–4.9 g/kg/day) per day added to a highly digestible diet such as Hill's *i/d*® (Leib 2004a), (Leib 2005)
- b) To increase fiber in dogs with chronic colitis: Add 1–2 tablespoonsful (15–30 mL) per 25 kg body weight to animal's regular diet. (Jergens 2007)
- c) 1 teaspoonful–2 tablespoonsful mixed with food every 12 hours (McConnell and Hughey 1987)

■ **CATS:**

- a) For chronic constipation: 1–4 teaspoonsful per meal added to canned cat food. Be sure cat is properly hydrated. (Washbau 2001)
- b) For adjunctive treatment of feline megacolon: 1–4 teaspoonsful mixed with food PO q12–24h (Scherk 2003b)

■ **HORSES:**

- a) For treatment of sand colic: 0.5 kg in 6–8 L (1 pound in 1.5–2 gallons) of water via stomach tube. Mix with water just before administration; simultaneously mixing water with psyllium as mixture is being pumped is ideal. May repeat as necessary as long as horse continues to pass feces and fluid does not accumulate in stomach. After initial treatment, may add up to 125 gm with each feeding; best if mixed with grain or sweet feed. Water must be available. (Calahan 1987)
- b) For sand impactions: 8 ounces in water via NG tube q24h. (Blikslager 2006a)

Monitoring

- Stool consistency, frequency

Client Information

- Contact veterinarian if patient begins vomiting
- Be sure animal has free access to water

Chemistry/Synonyms

Psyllium is obtained from the ripe seeds of varieties of *Plantago* species. The seed coating is high in content of hemicellulose mucilage that absorbs and swells in the presence of water.

Psyllium may also be known as *Metamucil*®; many other trade names are available.

Storage/Stability

Store psyllium products in tightly closed containers; protect from excess moisture or humidity.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Equine Enteric Colloid® (Techmix); *Equi-Phar*® Sweet Psyllium (Vedco); (not for horses intended for food); *Sandclear*® (Farnam), *Anipsyll*® Powder (AHC), *Purepsyll*® Powder (AHC), *Vita-Flex Sand Relief*® (Vita-Ilex), *Equa Aid Psyllium*® (Equi Aid); (OTC). Products may be available in 28 oz, 56 oz, 1 lb, 10 lb and 30 lb pails and are labeled for use in horses.

Vetasyll Fiber Tablets for Cats® 500 mg, & 1000 mg tablets in bottles of 60 or 180; (Virbac) (OTC); Labeled for use in cats. Also contains barley malt extract powder, acacia and thiamine.

HUMAN-LABELED PRODUCTS:

There are many human-approved products containing psyllium, most products contain approximately 3.4 grams of psyllium per rounded teaspoonful. Dosages of sugar-free products may be different from those containing sugar.

PYRANTEL PAMOATE

(pi-ran-tel) Strongid T®, Nemex®

ANTIPARASITIC**Prescriber Highlights**

- Pyrimidine anthelmintic used primarily for ascarids in a variety of species
- Contraindications: Severely debilitated animals
- Adverse Effects: Unlikely, emesis possible in small animals

Uses/Indications

Pyrantel has been used for the removal of the following parasites in dogs: ascarids (*Toxocara canis*, *T. leonina*), hookworms (*Ancylostoma caninum*, *Uncinaria stenocephala*), and stomach worm (*Physaloptera*). Although not approved for use in cats, it is useful for similar parasites and is considered safe to use.

Pyrantel is indicated (labeled) for the removal of the following parasites in horses: *Strongylus vulgaris* and *equinus*, *Parasacaris equorum*, and *Probstymayria vivipara*. It has variable activity against *Oxyuris equi*, *S. edentatus*, and small strongyles. Pyrantel is active against ileocecal tapeworm (*A. perfoliata*) when used at twice the recommended dose, although resistance has been reported.

Although there are apparently no pyrantel products approved for use in cattle, sheep, or goats, the drug is effective (as the tartrate) for the removal of the following parasites: *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Nematodirus* spp., *Chabertia* spp., *Cooperia* spp. and *Oesophagostomum* spp.

Pyrantel tartrate is indicated (labeled) for the removal or prevention of the following parasites in swine: large roundworms (*Ascaris suum*) and *Oesophagostomum* spp. The drug has activity against the swine stomach worm (*Hyoststrongylus rubidus*).

Although not approved, pyrantel has been used in pet birds and llamas. See the Dosage section for more information.

Pharmacology/Actions

Pyrantel acts as a depolarizing, neuromuscular-blocking agent in susceptible parasites, which paralyzes the organism. The drug possesses nicotine-like properties and acts similarly to acetylcholine. It also inhibits cholinesterase.

Pharmacokinetics

Pyrantel pamoate is poorly absorbed from the GI tract, thus allowing it to reach the lower GI in dogs, cats and equines. Pyrantel tartrate is absorbed more readily than the pamoate salt. Pigs and dogs absorb pyrantel tartrate more so than do ruminants, with peak plasma levels occurring 2–3 hours after administration. Peak plasma levels occur at highly variable times in ruminants.

Absorbed drug is rapidly metabolized and excreted into the urine and feces.

Contraindications/Precautions/Warnings

Use with caution in severely debilitated animals. The manufacturers usually recommend not administering the drug to severely debilitated animals.

Adverse Effects

When administered at recommended doses, adverse effects are unlikely. Emesis may possibly occur in small animals receiving pyrantel pamoate.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Pyrantel is considered safe to use in nursing veterinary patients.

Overdosage/Acute Toxicity

Pyrantel has a moderate margin of safety. Dosages up to approximately 7 times recommended generally result in no toxic reactions. In horses, doses of 20X yielded no adverse effects. The LD₅₀ in mice and rats for pyrantel tartrate is 170 mg/kg; >690 mg/kg for pyrantel pamoate in dogs.

Chronic dosing of pyrantel pamoate in dogs resulted in clinical signs when given at 50 mg/kg/day, but not at 20 mg/kg/day over 3 months. Clinical signs of toxicity that may be seen include increased respiratory rates, profuse sweating (in species with sweat glands), ataxia or other cholinergic effects.

Drug Interactions

- **DIETHYLCARBAMAZINE:** Increased risk for adverse effects
- **LEVAMISOLE:** Because of similar mechanisms of action (and toxicity), do not use concurrently with pyrantel
- **MORANTEL:** Because of similar mechanisms of action (and toxicity), do not use concurrently with pyrantel
- **ORGANOPHOSPHATES:** Increased risk for adverse effects
- **PIPERAZINE:** Pyrantel and piperazine have antagonistic mechanisms of action; do not use together

Doses

All doses are for pyrantel pamoate unless otherwise noted. **CAUTION:** Listed dosages are often not specified as to whether using the salt or base.

■ DOGS:

For susceptible parasites:

- a) For hookworms, or roundworms: 5 mg/kg PO after meals; repeat in 7–10 days (Willard 2003a)
- b) 15 mg/kg PO 30 minutes after a light meal. Re-treatment recommendations: For hooks: 2 weeks; every other week for 5–6 weeks (beginning at 1 week old) if bitch previously lost pups due to hookworm anemia. For Ascarids: Every other week for 3–4 treatments beginning at 2 weeks old if pups have heavy infestation; retreatment usually not necessary for mature animals. (Cornelius and Roberson 1986)
- c) Puppies: Can be treated as early as 2–3 weeks of age at 5–10 mg/kg PO; can be repeated every 2–3 weeks until at least 12 weeks of age. (Hoskins 2005d)
- d) For dogs weighing <5 lb: 10 mg/kg (as base) PO; for dogs weighing >5 lbs: 5 mg/kg (as base) PO. Treat puppies at 2, 3, 4, 6, 8, and 10 weeks of age. Treat lactating bitches 2–3 weeks after whelping. Do follow-up fecal 2–4 weeks after treating to determine need for retreatment. (Label directions; *Nemex® Tabs*—Pfizer)
- e) 20 mg/kg PO; be sure that liquid is well mixed before using; tablets may be broken for accurate dosing. Not approved for cats but very safe and effective. (Blagburn 2005b)

■ CATS:

For susceptible parasites:

- a) Ascarids, Hookworms, Physaloptera: 5 mg/kg, PO; repeat in 2 weeks (one time only for Physaloptera) (Dimski 1989)
- b) 10 mg/kg PO, repeat in 3 weeks (Kirk 1989)
- c) Kittens: Can be treated as early as 2–3 weeks of age at 5–10 mg/kg PO; can be repeated every 2–3 weeks until at least 12 weeks of age. (Hoskins 2005d)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 15–10 mg/kg PO, repeat in 2–3 weeks (Ivey and Morrissey 2000)

■ HORSES:

For susceptible parasites:

- a) 6.6 mg (as base)/kg PO; 13.2 mg (as base)/kg for cestodes (Robinson 1987), (Roberson 1988b)
- b) 19 mg/kg, PO (Brander, Pugh, and Bywater 1982)
- c) Pyrantel tartrate: 12.5 mg/kg, PO (Roberson 1988b)

■ SWINE:

For susceptible parasites:

- a) To remove *Ascaris suum* or *Oesophagostomum* spp.: Pyrantel tartrate: 22 mg/kg PO (or in feed at a rate of 800 g/ton) as a single treatment. For *Ascaris suum* only: in feed at a rate of 96 g/ton (2.6 mg/kg) for 3 days (Paul 1986) (Label instructions from several pyrantel tartrate premix products)
- b) Pyrantel tartrate: 22 mg/kg, PO; maximum of 2 grams per animal (Roberson 1988b)
- c) For ascarids and nodular worms in potbellied pigs: 6.6 mg/kg PO (Braun 1995)

■ CATTLE, SHEEP & GOATS:

For susceptible parasites:

- a) Pyrantel tartrate: 25 mg/kg, PO (Roberson 1988b)

■ **LLAMAS:**

For susceptible parasites:

- a) 18 mg/kg, PO for one day (Cheney and Allen 1989), (Fowler 1989)

■ **BIRDS:**

For intestinal nematodes:

- a) 4.5 mg/kg PO once. Repeat in 14 days. Suspension is non-toxic and palatable. (Clubb 1986)
- b) For nematodes: 100 mg/kg, PO as a single dose in psittacines and passerines (Marshall 1993)

Client Information

- Shake suspensions well before administering.

Chemistry/Synonyms

A pyrimidine-derivative anthelmintic, pyrantel pamoate occurs as yellow to tan solid and is practically insoluble in water and alcohol. Each gram of pyrantel pamoate is approximately equivalent to 347 mg (34.7%) of the base.

Pyrantel may also be known as: CP-10423-16, pyrantel embonate, pirantel pamoate, *Anthel*®, *Antiminth*®, *Ascarical*®, *Aut*®, *Bantel*®, *Cobantril*®, *Combantrin*®, *Combantrin*®, *Early Bird*®, *Helmex*®, *Helmintox*®, *Jaa Pyral*®, *Lombriareu*®, *Nemex*®, *Nemocid*®, *Pin-X*®, *Pirantrim*®, *Pyranthin*®, *Pyrantrin*®, *Pyrapam*®, *Reese's*® *Pinworm*, *Strongid*®, *Trilombrin*®, or *Vertel*®.

Storage/Stability/Compatibility

Pyrantel pamoate products should be stored in tight, light-resistant containers at room temperature (15–30°C) unless otherwise directed by the manufacturer.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Note: Many products available; a partial listing of products follows:

Pyrantel Pamoate Tablets: 22.7 mg (of base), 113.5 mg (of base); (OTC). Approved for use in dogs. A commonly known product is *Nemex*® *Tabs* (Pfizer).

Pyrantel Pamoate Oral Suspension: 4.54 mg/mL (as base) (for dogs only); in 60 mL, 120 mL 280 mL and 473 mL bottles; Many products are available; a commonly known trade name is *Nemex-2*® (Pfizer); (OTC)

Pyrantel Pamoate Oral Suspension: 50 mg/mL (of base); Many products are available; a commonly known trade name is *Strongid*® *T* (Pfizer); (OTC). Approved for use in horses not intended for food.

Pyrantel Pamoate Oral Paste: 43.9% w/w pyrantel base in 23.6 g (20 mL) paste (180 mg pyrantel base/mL); Several products are available; a commonly known trade name is *Strongid*® *Paste* (Pfizer); (OTC). Approved for use in horses not intended for food.

Pyrantel Tartrate 1.06% (4.8 g/lb) Top Dress: in 25 lb pails: *Strongid*® *C*® (Pfizer); (OTC). Labeled for use in horses (not intended for food).

Combination Products:

Praziquantel 18.2 mg/pyrantel pamoate 72.6 mg (as base); *Drontal*® *Tablets* (Bayer); (OTC). Approved for use in cats and kittens that are 4 weeks of age or older and weigh 1.5 lb. or greater.

Praziquantel 30 mg/pyrantel pamoate 30 mg; & Praziquantel 114 mg/pyrantel pamoate 114 mg Chewable Tablets: *Virbantel Flavored Chewables*® (Virbac); (OTC). Approved for use in dogs.

Praziquantel/pyrantel pamoate plus febantel Tablets: Small, medium and large dog sizes. *Drontal*® *Plus Tablets* (Bayer); (Rx); Approved for dogs and puppies 3 weeks of age or older and weighing 2 lb. or greater.

Ivermectin/Pyrantel Oral Chewable Tablets: 68 mcg/57 mg, 136 mcg/114mg, 272 mcg/228 mg; *Heartgard*® *Plus Chewables* (Merial); *Tri-Heart*® *Plus Chewable Tablets* (Schering); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

Pyrantel Pamoate Oral Suspension or Liquid: 50 mg/mL pyrantel (as pamoate) in 30 mL and 60 mL; *Antiminth*® (Pfizer Labs); *Reese's*® *Pinworm* (Reese); *Pin-X*® (Effcon); (OTC)

Pyrantel Soft-gel Capsules: 180 mg (equivalent to 62.5 mg pyrantel base); *Pin-Rid*® (Apothecary); *Reese's*® *Pinworm* (Reese); (OTC)

PYRIDOSTIGMINE BROMIDE

(peer-i-oh-*stig*-meen) Mestinon®

ANTICHOLINESTERASE AGENT**Prescriber Highlights**

- Anticholinesterase used for treatment of myasthenia gravis
- Contraindications: hypersensitivity to this class of compounds or bromides, patients with mechanical or physical obstructions of the urinary or GI tract
- Caution: bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases
- Adverse Effects: Usually dose related cholinergic effects GI (nausea, vomiting, diarrhea), salivation, sweating, respiratory (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic (miosis, blurred vision, lacrimation), cardiovascular (bradycardia or tachycardia, cardiospasm, hypotension, cardiac arrest), muscle cramps, & weakness

Uses/Indications

Pyridostigmine is used in the treatment of myasthenia gravis (MG) in dogs (and rarely in cats). It is considered to be much more effective in acquired MG, than in congenital MG.

Pharmacology/Actions

Pyridostigmine inhibits the hydrolysis of acetylcholine by directly competing with acetylcholine for attachment to acetylcholinesterase. Because the pyridostigmine-acetylcholinesterase complex is hydrolyzed at a much slower rate than the acetylcholine-acetylcholinesterase complex, acetylcholine tends to accumulate at cholinergic synapses with resultant cholinergic activity.

At usual doses, pyridostigmine does not cross into the CNS (quaternary ammonium structure), but overdoses can cause CNS effects.

Pharmacokinetics

Pyridostigmine is only marginally absorbed from the GI tract and absorption may be more erratic with the sustained-release tablets than the regular tablets. The onset of action after oral dosing is generally within one hour.

At usual doses, pyridostigmine is apparently distributed to most tissues, but not to the brain, intestinal wall, fat or thymus. The drug crosses the placenta.

Pyridostigmine is metabolized by both the liver and hydrolyzed by cholinesterases.

Contraindications/Precautions/Warnings

Pyridostigmine is contraindicated in patients hypersensitive to this class of compounds or bromides, or in those who have mechanical or physical obstructions of the urinary or GI tract.

The drug should be used with caution in patients with bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases.

Adverse Effects

Adverse effects associated with pyridostigmine are generally dose related and cholinergic in nature. Although usually mild and easily treatable with dosage reduction, severe adverse effects are possible (see Overdosage below).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Pyridostigmine is excreted in maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity

Overdosage of pyridostigmine may induce a cholinergic crisis. Clinical signs of cholinergic toxicity can include: GI effects (nausea, vomiting, diarrhea), salivation, sweating (species with sweat glands), respiratory effects (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects (miosis, blurred vision, lacrimation), cardiovascular effects (bradycardia or tachycardia, cardiospasm, hypotension, cardiac arrest), muscle cramps, and weakness.

Overdoses in myasthenic patients can be very difficult to distinguish from the effects associated with a myasthenic crisis. The time of onset of clinical signs or an edrophonium challenge may help to distinguish between the two.

Treatment of pyridostigmine overdosage consists of both respiratory and cardiac supportive therapy and atropine if necessary. Refer to the atropine monograph for more information on its use for cholinergic toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyridostigmine and may be of significance in veterinary patients:

- **ATROPINE:** Atropine will antagonize the muscarinic effects of pyridostigmine but concurrent use should be used cautiously as atropine can mask the early clinical signs of cholinergic crisis
- **CORTICOSTEROIDS:** May decrease the anticholinesterase activity of pyridostigmine. After stopping corticosteroid therapy, drugs like pyridostigmine may cause increased anticholinesterase activity
- **DEXPANTHENOL:** Theoretically, dexpanthenol may have additive effects when used with pyridostigmine
- **DRUGS WITH NEUROMUSCULAR BLOCKING ABILITY** (e.g., aminoglycoside antibiotics): May necessitate increased dosages of pyridostigmine in treating or diagnosing myasthenic patients
- **MAGNESIUM:** Anticholinesterase therapy may be antagonized by administration of parenteral magnesium therapy, as it can have a direct depressant effect on skeletal muscle

- **MUSCLE RELAXANTS:** Pyridostigmine may prolong the Phase I block of depolarizing muscle relaxants (e.g., **succinylcholine**, **decamethonium**) and edrophonium antagonizes the actions of non-depolarizing neuromuscular blocking agents (e.g., **pancuronium**, **tubocurarine**, **gallamine**, **vecuronium**, **atracurium**, etc.)

Doses

■ DOGS:

For myasthenia gravis (MG):

- a) 0.5–3 mg/kg (either PO or stomach tube) q8–12h. Start at low end of dose and increase as necessary to avoid a cholinergic crisis. (Dewey 1999)
- b) 1–3 mg/kg PO q8–12h (Inzana 2000)
- c) For acquired MG: After oral regurgitation is abolished with parenteral therapy (neostigmine), may begin oral therapy with pyridostigmine at 7.5–30 mg PO two times a day. Once patient is stable and infections have resolved, begin corticosteroid therapy (antiinflammatory doses of prednisone) and continue concurrently with anticholinesterase drugs for 2 weeks, then pyridostigmine may be gradually reduced. (Pedroia 1989)
- d) 0.5–3 mg/kg PO two to three times a day. If no response, add prednisone (0.5–1 mg/kg day; increase to 1–2 mg/kg after a few days). (Kornegay 2006)
- e) 0.5–1 mg/kg PO two to three times a day with or without prednisone (2 mg/kg PO twice daily). Not uncommon for dogs to fully recover without treatment (spontaneous remission). (LeCouteur 2005)

■ CATS:

For myasthenia gravis (MG):

- a) For acquired MG: Cats are sensitive to anticholinesterase agents. Do not exceed 0.25 mg/kg/day, PO initially in cats (Fenner 1989)
- b) 1–3 mg/kg PO q8–12h (Inzana 2000)
- c) 0.5–3 mg/kg PO per day with corticosteroids (Wheeler 2006)

Monitoring

- Animals should be routinely monitored for clinical signs of cholinergic toxicity (see Overdosage section above) and efficacy of the therapy

Client Information

- Clients should be instructed to report to the veterinarian clinical signs of excessive salivation, GI disturbances, weakness, or difficulty breathing

Chemistry/Synonyms

An anticholinesterase agent, pyridostigmine bromide is a synthetic quaternary ammonium compound that occurs as an agreeable smelling, bitter tasting, hygroscopic, white or practically white, crystalline powder. It is freely soluble in water and in alcohol. The pH of the commercially available injection is approximately 5.

Pyridostigmine Bromide may also be known as: pyridostigmini bromidum, *Distinon*®, *Kalymin*®, *Mestinon*®, or *Regonol*®.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, store pyridostigmine products at room temperature. The oral solution and injection should be protected from light and freezing. Pyridostigmine tablets should be kept in tight containers.

The extended-release tablets may become mottled with time, but this does not affect their potency.

Pyridostigmine injection is unstable in alkaline solutions.

It is reportedly physically **compatible** with glycopyrrolate, heparin sodium, hydrocortisone sodium succinate, potassium chloride, and vitamin B-complex with C. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pyridostigmine Bromide Tablets: 60 mg; *Mestinon*® (ICN); generic, (Rx)

Pyridostigmine Bromide Extended-Release Tablets: 180 mg; *Mestinon*® (ICN); (Rx)

Pyridostigmine Bromide Syrup: 12 mg/mL in 480 mL; *Mestinon*® (ICN); (Rx)

Pyridostigmine Bromide Injection: 5 mg/mL in 2 mL amps; *Mestinon*® (ICN); (Rx)

PYRIDOXINE HCL (VITAMIN B-6)

(peer-ih-dox-een)

NUTRITIONAL B VITAMIN, ANTIDOTE

Prescriber Highlights

- ▶ Pyridoxine may be beneficial in the treatment of isoniazid or crinidine toxicity, or delaying cutaneous toxicity of *Doxil*® (liposomal doxorubicin)
- ▶ Overdoses may cause peripheral neuropathy

Uses/Indications

Pyridoxine use in veterinary medicine is relatively infrequent. It may be of benefit in the treatment of isoniazid (INH) or crinidine (an older rodenticide) toxicity. Pyridoxine deficiency is apparently extremely rare in dogs or cats able to ingest food. Cats with severe intestinal disease may have a greater requirement for pyridoxine in their diet. Experimentally, pyridoxine has been successfully used in dogs to reduce the cutaneous toxicity associated with doxorubicin containing pegylated liposomes (*Doxil*®). Pyridoxine has been demonstrated to suppress the growth of feline mammary tumors (cell line FRM) *in vitro*.

In humans, labeled uses for pyridoxine include pyridoxine deficiency and intractable neonatal seizures secondary to pyridoxine dependency syndrome. Unlabeled uses include premenstrual syndrome (PMS), carpal tunnel syndrome, tardive dyskinesia secondary to antipsychotic drugs, nausea and vomiting in pregnancy, hyperoxaluria type 1 and oxalate kidney stones, and for the treatment of isoniazid (INH), cycloserine, hydrazine or Gyometra mushroom poisonings.

Pharmacology/Actions

In erythrocytes, pyridoxine is converted to pyridoxal phosphate and, to a lesser extent, pyridoxamine, which serve as coenzymes for metabolic functions affecting protein, lipid and carbohydrate utilization. Pyridoxine is necessary for tryptophan conversion to

serotonin or niacin, glycogen breakdown, heme synthesis, synthesis of GABA in the CNS, and oxalate conversion to glycine. Pyridoxine can act as an antidote by enhancing the excretion of cycloserine or isoniazid.

Pyridoxine requirements increase as protein ingestion increases.

Pharmacokinetics

Pyridoxine is absorbed from the GI tract primarily in the jejunum. Malabsorption syndromes can significantly impair pyridoxine absorption. Pyridoxine is not bound to plasma proteins, but pyridoxal phosphate is completely bound to plasma proteins. Pyridoxine is stored primarily in the liver with smaller amounts stored in the brain and muscle. It is biotransformed in the liver and various tissues, and excreted almost entirely as metabolites into the urine. Elimination half-life in humans is approximately 15–20 days.

Contraindications/Precautions/Warnings

Weigh potential risks versus benefits in patients with documented sensitivity to pyridoxine.

Adverse Effects

Pyridoxine is generally well tolerated unless doses are large (see Overdosage). In humans, paresthesias and somnolence have been reported. Reduced serum folic acid levels have occurred.

Reproductive/Nursing Safety

While pyridoxine is a nutritional agent and very safe at recommended doses during pregnancy, very large doses during pregnancy can cause a pyridoxine dependency syndrome in neonates.

Pyridoxine administration at low dosages should be safe during nursing. Pyridoxine requirements of the dam may be increased during nursing.

Overdosage/Acute Toxicity

Single overdoses are not considered overly problematic, unless they are massive. Laboratory animals given 3–4 g/kg developed seizures and died. Dogs (Beagles) repeatedly given 3 gram oral daily doses developed uncoordinated gait and neurologic signs. Neuronal lesions were noted in sensory, dorsal root ganglia, and trigeminal ganglia. Signs generally resolved over a 2-month drug free period.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyridoxine and may be of significance in veterinary patients:

- **CHLORAMPHENICOL:** May cause increased pyridoxine requirements
- **ESTROGENS:** May cause increased pyridoxine requirements
- **HYDRALAZINE:** May cause increased pyridoxine requirements
- **IMMUNOSUPPRESSANTS** (e.g., **azathioprine**, **chlorambucil**, **cyclophosphamide**, **corticosteroids**): May cause increased pyridoxine requirements
- **ISONIAZID:** May cause increased pyridoxine requirements
- **PENICILLAMINE:** May cause increased pyridoxine requirements
- **LEVODOPA:** Pyridoxine may reduce levodopa efficacy (no interaction when levodopa is used with carbidopa)
- **PHENOBARBITAL:** High dose pyridoxine may decrease phenobarbital serum levels
- **PHENYTOIN:** High dose pyridoxine may decrease phenytoin serum concentration

Laboratory Considerations

The following laboratory alterations have been reported in humans with pyridoxine and may be of significance in veterinary patients:

- **Urobilinogen in the spot test using Ehrlich's reagent:** Pyridoxine may cause false-positive results
- **AST:** Excessive dosages of pyridoxine may elevate AST

Doses

■ DOGS / CATS:

- a) Dogs: For isoniazid (INH) toxicity: If quantity of INH ingested is known, give pyridoxine on a mg for mg (1:1) basis. If it is not known, give pyridoxine initially at 71 mg/kg as a 5–10% IV infusion over 30–60 minutes (some sources say it can be given as an IV bolus). Pyridoxine injection can usually be obtained from human hospital pharmacies. Do not use injectable B-complex vitamins. (Gwaltney-Brant 2003)
- b) To replace pyridoxine antagonized by crimidine ingestion: 20 mg/kg IV (Dalefield and Oehme 2006)
- c) Dogs: To delay the development of cutaneous toxicity (PPES; palmer-plantar-dyerythrodesesthesia) associated with doxorubicin containing pegylated liposomes (*Doxil*®): 50 mg PO three times daily during chemotherapy protocol period. (Vail, Chun et al. 1998)

Monitoring

- Other than evaluating efficacy for its intended use, no significant monitoring is required

Client Information

- Do not give more than prescribed by the veterinarian
- Contact veterinarian if animal develops any abnormal signs such as difficulty walking, using stairs, etc.

Chemistry/Synonyms

Pyridoxine (vitamin B6) is a water-soluble vitamin present in many foods (liver, meat, eggs, cereals, legumes, and vegetables). The commercially available form (pyridoxine HCl) found in medications is obtained synthetically. Pyridoxine HCl occurs as white or practically white, crystals or crystalline powder with a slightly bitter, salty taste. It is freely soluble in water and slightly soluble in alcohol.

Pyridoxine or Vitamin B6 may also be known by the following synonyms or analogs: adermin, pyridoxal, pyridoxal-5-phosphate, pyridoxamine, pirodoxamina, pirodosima, pirodolum, pirodosina, *Aminoxin*®, and *Vitelle Nestrex*®.

Storage/Stability/Compatibility

Unless otherwise specified by the manufacturer, pyridoxine tablets should be stored below 40°C (104°F), preferably between 15–30°C (59–86°F), in well-closed containers protected from light.

Pyridoxine HCl injection should be stored below 40°C (104°F), preferably between 15–30°C (59–86°F), protected from light and freezing.

Pyridoxine HCl injection can be administered undiluted or added to commonly used IV solutions. It is reportedly **compatible** with doxapram when mixed in a syringe and with fat emulsion 10%. It is reportedly **incompatible** with alkaline or oxidizing solutions, and iron salts.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No single ingredient pyridoxine products were located. There are a multitude of various veterinary-labeled products that contain pyridoxine as one of several ingredients.

HUMAN-LABELED PRODUCTS:

Pyridoxine Tablets: 25 mg, 50 mg, 100 mg, 250 mg, & 500 mg; *Vitelle Nestrex*® (Fielding), generic; (OTC)

Pyridoxine (as pyridoxal-5'-phosphate) Tablets (enteric-coated): 20 mg; *Aminoxin*® (Tyson); (OTC)

Pyridoxine HCl Injection: 100 mg/mL in 1 mL vials; generic; (Rx)

Pyridoxine is also an ingredient in many combination products (e.g., B-Complex, multivitamins).

PYRILAMINE MALEATE

(pye-ril-a-meen) Histall®, Equiphed®

ANTI-HISTAMINE

Prescriber Highlights

- ▶ **Injectable antihistamine**
- ▶ **Contraindications:** None noted
- ▶ **Adverse Effects:** HORSES: CNS stimulation (nervousness, insomnia, convulsions, tremors, ataxia), palpitation, GI disturbances, CNS depression (sedation), muscular weakness, anorexia, lassitude & incoordination
- ▶ **Drug Interactions**

Uses/Indications

Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects; predominantly used in horses.

Pharmacology/Actions

Antihistamines (H₁-receptor antagonists) competitively inhibit histamine at H₁ receptor sites. They do not inactivate, nor prevent the release of histamine, but can prevent histamine's action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). Pyrilamine is considered to be less sedating and have fewer anticholinergic effects when compared to most other antihistamines.

Pharmacokinetics

The pharmacokinetics of this agent have apparently not been extensively studied.

Contraindications/Precautions/Warnings

The manufacturer indicates that the use of this product "... should not supersede the use of other emergency drugs and procedures."

Adverse Effects

Adverse effects in horses can include CNS stimulation (nervousness, insomnia, convulsions, tremors, ataxia), palpitation, GI disturbances, CNS depression (sedation), muscular weakness, anorexia, lassitude and incoordination.

Reproductive/Nursing Safety

At usual doses, pyrilamine is probably safe to use during pregnancy. Rats and mice treated with 10–20 times the human dose had an increased frequency of embryonic, fetal or perinatal death, but a study in pregnant women, showed no increase in teratogenic or fetotoxic rates.

It is unknown if pyrilamine enters milk.

Overdosage/Acute Toxicity

Treatment of overdosage is supportive and symptomatic. One manufacturer (*Histavet-P*®—Schering) suggests using “careful titration” of barbiturates to treat convulsions, and analeptics (caffeine, ephedrine, or amphetamines) to treat CNS depression. Most toxicologists however, recommend avoiding the use of CNS stimulants in the treatment of CNS depressant overdoses. Phenytoin (IV) is recommended in the treatment of seizures caused by antihistamine overdose in humans; barbiturates and diazepam are to be avoided.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrilamine and may be of significance in veterinary patients:

- **ANTICOAGULANTS (heparin, warfarin):** Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin
- **CNS DEPRESSANT DRUGS:** Increased sedation can occur if pyrilamine is combined with other CNS depressant drugs
- **EPINEPHRINE:** Pylamine may enhance the effects of epinephrine

Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to antigen **skin testing**. In humans, it is suggested that antihistamines be discontinued at least 4 days before testing.

Doses■ **DOGS:**

- a) 12.5–25 mg PO four times a day; 25–125 mg IM (Swinyard 1975)

■ **CATTLE:**

- a) 0.5–1.5 grams IM (Swinyard 1975)
- b) For adjunctive treatment of aseptic laminitis: 55–110 mg/100 kg IV or IM (Berg 1986)

■ **HORSES:** (Note: ARCI UCGFS Class 3 Drug)

- a) 0.88–1.32 mg/kg (2–3 mL of 20 mg/mL solution per 100 lbs body weight) IV (slowly), IM or SC; may repeat in 6–12 hours if necessary. Foals: 0.44 mg/kg (1 mL of 20 mg/mL solution per 100 lbs. body weight) IV (slowly), IM or SC; may repeat in 6–12 hours if necessary. (Package Insert; *Histavet-P*®—Schering)
- b) 1 mg/kg IV, IM or SC (Robinson 1987)
- c) 0.5–1.5 grams IM (Swinyard 1975)

■ **SHEEP, SWINE:**

- a) 0.25–0.5 gram IM (Swinyard 1975)

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

An ethylenediamine antihistamine, pyrilamine maleate occurs as a white, crystalline powder with a melting range of 99–103°. One gram is soluble in approximately 0.5 mL of water or 3 mL alcohol.

Pyrilamine Maleate may also be known as: pyranisamine hydrochloride, pyrilamine hydrochloride, mepyramine hydrochloride, mepyramini maleas, myranisamine maleate, myrilamine maleate, mepyramine maleate, *Anihist*®, *Alergitanil*®, *Antemesyl*®, *Anthisan*®, *Anthisan*®, *Equi-Phar*®, *Equi-Hist*®, *Equiphed*®, *Fluidasa*®, *Histall*®, *Histagranules*®, *Histamed*®, *Mepyraderm*®, *Mepyrimal*®, *Pyramine*®, *Pyriped*®, *Relaxa-Tabs*®, and *Tri-Hist*®.

Storage/Stability

Avoid freezing the injectable product.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Pyrilamine Granules: 600 mg/oz in 20 oz containers; *Histall*® (AHC); (OTC). Labeled for use in horses. Do not use at least 72 hours before sporting events.

Pseudoephedrine HCl 600 mg/oz and Pylamine maleate 600 mg/oz Granules: in 20 oz, 5 lb and 10 lb containers; *Equiphed*® (AHC), *Equi-Phar Equi-Hist 1200 Granules*® (Vedco), *Tri-Hist Granules*® (Neogen), *Histagranules*® (Butler); (Rx). Labeled for use in horses. Do not use at least 72 hours before sporting events.

Pyrilamine 600 mg/oz and Guaifenesin 2400 mg/oz Granules: in 20 oz, 5 lb and 25 lb containers; *Anihist*® (AHC), *Hist-EQ*® (Butler); (OTC). Labeled for use in horses. Do not use at least 72 hours before sporting events.

There are also combination cough syrups containing pyrilamine labeled for use in small animals.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

PYRIMETHAMINE

(pye-ri-meth-a-meen) Daraprim®

ANTIPROTOZOAL

Note: Also see the Pyrimethamine/Sulfadiazine, and Sulfadiazine/Trimethoprim monographs

Prescriber Highlights

- Folic acid inhibitor used primarily (in combination) for toxoplasmosis, *H. americanum*, neosporosis, & equine protozoal encephalomyelitis
- Contraindications: Hypersensitive to pyrimethamine
- Caution: Hematologic disorders; cats
- Adverse Effects: **SMALL ANIMALS:** Anorexia, malaise, vomiting, depression, & bone marrow depression (anemia, thrombocytopenia, leukopenia). Cats may be more likely to develop adverse reactions. **HORSES:** Leukopenias, thrombocytopenia, & anemias; Baker's yeast or folic acid may treat/prevent.
- Potentially teratogenic; avoid use in pregnancy
- Dosage form (25 mg tab only) may be inconvenient; unpalatable to cats

Uses/Indications

In veterinary medicine, pyrimethamine is used to treat *Hepatozoon americanum* infections, and toxoplasmosis in small animals (often in combination with sulfonamides). In horses, it is used to treat equine protozoal myeloencephalitis, sometimes called equine toxoplasmosis.

In humans, pyrimethamine is used for the treatment of toxoplasmosis and as a prophylactic agent for malaria.

Pharmacology/Actions

Pyrimethamine is a folic acid antagonist similar to trimethoprim. It acts by inhibiting the enzyme, dihydrofolate reductase, that catalyzes the conversion of dihydrofolic acid to tetrahydrofolic acid.

Pharmacokinetics

No pharmacokinetic data was located for veterinary species. In humans, pyrimethamine is well absorbed from the gut after oral administration. It is distributed primarily to the kidneys, liver, spleen, and lungs, but does cross the blood-brain barrier. It has a volume of distribution of about 3 L/kg and is 80% bound to plasma proteins. Pyrimethamine enters milk in levels greater than those found in serum and can be detected in milk up to 48 hours after dosing.

In humans, plasma half-life is approximately 3–5 days. It is unknown how or where the drug is metabolized, but metabolites are found in the urine.

Contraindications/Precautions/Warnings

Pyrimethamine is contraindicated in patients hypersensitive to it and should be used cautiously in patients with preexisting hematologic disorders. Some clinicians recommend avoiding its use in cats because of its adverse effect profile.

Adverse Effects

In small animals, anorexia, malaise, vomiting, depression, and bone marrow depression (anemia, thrombocytopenia, leukopenia) have been seen. Adverse effects may be more prominent in cats and noted 4–6 days after starting combination therapy. Some clinicians recommend avoiding its use in this species. Hematologic effects can develop rapidly and frequent monitoring is recommended, particularly if therapy persists longer than 2 weeks. Oral administration of folic acid at 1 mg/kg PO, folic acid 5 mg/day, or Brewer's yeast 100 mg/kg/day have been suggested to alleviate adverse effects.

The drug is unpalatable to cats when mixed with food and the 25 mg tablet dosage size makes successful dosing a challenge.

In horses, pyrimethamine has caused leukopenias, thrombocytopenia and anemias when used in combination with sulfonamides. Baker's yeast and folic acid have been suggested to antagonize these adverse effects. Alternatively, folic acid supplement may be used (an example is Folic Acid and Vitamin E Pak from Buckeye Feed Mills in Dalton, Ohio).

Reproductive/Nursing Safety

Pyrimethamine has been demonstrated to be teratogenic in rats. Fetal abnormalities have been seen in foals after mares have been treated, however, it has been used in treating women with toxoplasmosis during pregnancy. Clearly, the risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available (e.g., clindamycin in small animals). Concomitant administration of folic acid has been recommended if the drug is to be used during pregnancy by some, but others state that pregnant mares should not receive folic acid during therapy as it may exacerbate fetal abnormalities or mortality. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Pyrimethamine is excreted in maternal milk; consider using milk replacer.

Overdosage/Acute Toxicity

Reports of acute overdosage of pyrimethamine in animals were not located. In humans, vomiting, nausea, anorexia, CNS stimulation (including seizures), and hematologic effects can be seen.

Recommendations for treatment include: standard procedures in emptying the gut or preventing absorption, parenteral barbiturates for seizures, folic acid for hematologic effects, and long-term monitoring (at least 1 month) of renal and hematopoietic systems.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrimethamine and may be of significance in veterinary patients:

- **p-AMINO BENZOIC ACID (PABA):** PABA is reportedly antagonistic towards the activity of pyrimethamine; clinical significance is unclear
- **SULFONAMIDES:** Pyrimethamine is synergistic with sulfonamides in activity against toxoplasmosis (and malaria)
- **TRIMETHOPRIM:** Use with pyrimethamine/sulfa is not recommended in humans as adverse effects may be additive, however, this combination has been used clinically in horses

Doses

■ DOGS:

For protozoal diseases:

- a) For toxoplasmosis: 0.5–1 mg/kg PO once daily for 2 days, then 0.25 mg/kg PO once daily for 2 weeks. Given with sulfadiazine at 30–50 mg/kg PO divided two to four times a day for 1–2 weeks (Murtaugh 1988)
- b) For Toxoplasmosis: 0.25–0.5 mg/kg once daily for 28 days; For Neospora (with trimethoprim sulfa): 1 mg/kg once daily for 28 days; For *Hepatozoon canis* (with trimethoprim sulfa and clindamycin): 0.25–0.5 mg/kg once daily for 2–4 weeks (Lappin 2000)
- c) For *Hepatozoon americanum*: Trimethoprim/sulfa (15 mg/kg PO q12h), pyrimethamine (0.25 mg/kg PO q24h), and clindamycin (10 mg/kg q8h). Once remission attained, decoquinatone (see monograph) can maintain. (Baneth 2007)
- d) For *Hepatozoon americanum*: Trimethoprim/sulfa (15 mg/kg PO q12h for 14 days), pyrimethamine (0.25 mg/kg PO q24h for 14 days), and clindamycin (10 mg/kg q8h for 14 days). Once remission attained, decoquinatone (see monograph) can maintain.

For neosporosis: pyrimethamine (1 mg/kg PO daily) with trimethoprim/sulfa (15–30 mg/kg PO twice daily. (Blagburn 2005a)

■ CATS: See warnings above.

For toxoplasmosis:

- a) 0.5–1 mg/kg PO once daily for 2 days, then 0.25 mg/kg PO once daily for 2 weeks. Given with sulfadiazine at 30–50 mg/kg PO divided two to four times a day for 1–2 weeks (Murtaugh 1988)
- b) For enteroepithelial cycle: 2 mg/kg, PO once daily. For extraintestinal cycle: 0.5–1 mg/kg PO divided two to three times daily combined with sulfonamides (e.g., triple sulfa, sulfadiazine) at 60 mg/kg PO or IM divided two to three times daily (Lappin 1989)
- c) For protozoal myocarditis: Pyrimethamine 1 mg/kg PO once daily for 3 days, then decrease dose to 0.5 mg/kg PO once a day, with sulfadimethoxine 25 mg/kg PO, IV, or IM once a day (Ogburn 1988)
- d) Pyrimethamine: 0.5 mg/kg PO per day with sulfadiazine at 30 mg/kg, PO q12h for 7–10 days. Do not use continuously for longer than 2 weeks. Supplementation with folic acid 5 mg/day or folic acid 1 mg/kg/day may alleviate toxicity. (Swango, Bankemper, and Kong 1989)

■ **HORSES:**

See also the next monograph (Pyrimethamine + Sulfadiazine)
For equine protozoal myeloencephalitis:

- a) Pyrimethamine 1 mg/kg PO once a day for 90–120 days (or longer). Given with a sulfa or potentiated sulfa (sulfadiazine 20 mg/kg PO once or twice a day). Monitor: CBC's (Moore 1999); (MacKay, Granstrom et al. 2000)

■ **BIRDS:**

For Coccidian organisms in raptors:

- a) 0.5 mg/kg PO twice daily for 14–28 days (especially effective against Toxoplasmosis, Atoxoplasmosis and Sarcocystis). (Jones 2007b)

Monitoring

- See adverse effects; CBC with platelet count
- Clinical efficacy

Client Information

- Clients should be instructed to monitor for clinical signs of abnormal bleeding, lassitude, etc. that may signal development of hematologic disorders.
- Accurate dosing of the tablets in cats may be very difficult as only 25 mg tablets are commercially available. Preferably, custom prepared capsules containing the accurate dosage should be prepared.

Chemistry/Synonyms

An aminopyrimidine agent structurally related to trimethoprim, pyrimethamine occurs as an odorless, white, or almost white, crystalline powder or crystals. It is practically insoluble in water and slightly soluble in alcohol.

Pyrimethamine may also be known as: BW-50-63, pirimetamina, pyrimethaminum, RP-4753, *Daraprim*®, *Malocide*®, or *Pirimecidan*®.

Storage/Stability/Compatibility

Pyrimethamine tablets should be stored in tight, light-resistant containers.

Pyrimethamine tablets may be crushed to make oral suspensions of the drug. Although stable in an aqueous solution, sugars tend to adversely affect the stability of pyrimethamine. If cherry syrup, corn syrup, or sucrose-containing liquids are used in the preparation of the suspension, it is recommended to store the suspension at room temperature and discard after 7 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pyrimethamine Tablets: 25 mg; *Daraprim*® (GlaxoSmithKline); (Rx)

PYRIMETHAMINE + SULFADIAZINE

(pye-ri-meth-a-meen + sul-fa-dye-a-zeen) ReBalance®

ANTIPROTOZOAL

Note: Also see the Pyrimethamine, and Sulfadiazine/Trimethoprim monographs

Prescriber Highlights

- ▶ Tetrahydrofolic acid inhibitor suspension labeled for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*
- ▶ May cause bone marrow suppression, GI effects, & "treatment crisis" (patient's signs worsen after beginning therapy)
- ▶ Daily treatment may be required for 3–9 months

Uses/Indications

ReBalance® (pyrimethamine/sulfadiazine suspension in a 1:20 concentration) is labeled for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*. Although not labeled for use in small animals it potentially could be useful for treating protozoal infections such as Toxoplasmosis in cats or Neosporosis in dogs.

Pharmacology/Actions

Sulfonamides inhibit the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA) by competing with PABA for dihydropteroate synthase. Pyrimethamine blocks the conversion of DFA to tetrahydrofolic acid by inhibiting dihydrofolate reductase. When sulfas and dihydrofolate reductase inhibitors (e.g., trimethoprim, pyrimethamine) are used together, synergistic effects can occur. When comparing pyrimethamine and trimethoprim, pyrimethamine is more active against protozoal dihydrofolate reductase and trimethoprim is more active against bacterial dihydrofolate reductase.

Pharmacokinetics

No specific information was located for the pharmacokinetics of this drug combination and dosage form (oral suspension) in horses. Previous reports in horses using other dosage forms reported pyrimethamine oral bioavailability of approximately 56% and elimination half-life of about 12 hours. CNS levels are approximately 25–50% of those found in plasma. Sulfadiazine is apparently well absorbed after oral administration to horses and enters the CSF. Volume of distribution is approximately 0.58 L/kg; elimination half-life is about 3–4 hours.

Contraindications/Precautions/Warnings

This drug combination is contraindicated in horses hypersensitive to either pyrimethamine or sulfadiazine. It should not be used in horses intended for human consumption. Because it may cause bone marrow suppression, use with caution in horses with preexisting hematologic abnormalities or those receiving other drugs that may cause bone marrow suppression.

Adverse Effects

Adverse effects in horses reported during field trials for pyrimethamine/sulfadiazine suspension include bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia),

reduced appetite/anorexia, loose stools/diarrhea, and urticaria. CNS effects may be noted (seizures, depression), but are probably a result of the disease (EPM).

Baker's yeast or folic acid have been suggested to antagonize the drug combination's bone marrow depressive effects, but efficacy has not been proven.

During the initial period (first few days) of treatment, neurologic signs may worsen—so-called treatment crisis—and may persist up to 5 weeks. It is thought this may be the result of an inflammatory reaction secondary to dying parasites in the central nervous system.

Reproductive/Nursing Safety

The label for *ReBalance*® (pyrimethamine/sulfadiazine suspension) states that the safe use of this product in horses for breeding purposes, during pregnancy, or in lactating mares has not been evaluated. Pyrimethamine has been demonstrated to be teratogenic in rats. Fetal abnormalities have been seen in foals after mares have been treated; however, it has been used in treating women with toxoplasmosis during pregnancy. Risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available. Some have recommended concomitant administration of folic acid if the drug is to be used during pregnancy, but others state that pregnant mares should not receive folic acid during therapy as it may exacerbate fetal abnormalities or mortality. In humans, the FDA categorizes pyrimethamine as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Sulfas cross the placenta and fetal serum levels may be up to 50% of that found in maternal serum. Teratogenicity has been reported in some laboratory animals when given at very high doses. Sulfas should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk. Pyrimethamine is excreted in maternal milk and safety for nursing offspring has not been established; consider using milk replacer.

Overdosage/Acute Toxicity

Acute overdosage information for pyrimethamine/sulfadiazine in horses (greater than 2X) was not located. *ReBalance*® (pyrimethamine/sulfadiazine suspension) was administered at 2X the labeled dose for 92 days to 49 horses. Signs noted included loose stools, slight increases in ALP in some horses, declines in RBC, HCT, Hgb, and PCV, and depressed appetite.

Drug Interactions

The label for *ReBalance*® (pyrimethamine/sulfadiazine suspension) states that the safety of this product with concomitant therapies in horses has not been evaluated.

In humans, the following drug interactions with sulfas and/or pyrimethamine have been reported or are theoretical and may be of significance in veterinary patients:

- **ANTACIDS:** May decrease the bioavailability of sulfonamides if administered concurrently
- **HIGHLY PROTEIN-BOUND DRUGS** (e.g., **methotrexate**, **phenylbutazone**, **thiazide diuretics**, **salicylates**, **probenecid**, **phenytoin**, **warfarin**): Sulfonamides may displace other highly bound drugs
- **p-AMINO BENZOIC ACID (PABA):** PABA is reportedly antagonistic towards the activity of pyrimethamine; clinical significance is unclear

- **TRIMETHOPRIM:** Use with pyrimethamine/sulfa is not recommended in humans as adverse effects may be additive, however, this combination has been used clinically in horses

Laboratory Considerations

The following laboratory alterations have been reported in humans taking sulfonamides and may be of significance in veterinary patients:

- **Urine glucose:** Sulfonamides may give false-positive results when using the Benedict's method

Doses

■ HORSES:

For treatment of EPM:

- a) 20 mg/kg sulfadiazine with 1 mg/kg pyrimethamine; equivalent to 4 mL of *ReBalance*® suspension per 50 kg (110 lb) body weight PO once daily at least 1 hour before feeding with hay or grain. Administer using a suitable oral dosing syringe; insert nozzle through the interdental space and deposit the dose on the back of the tongue by depressing the plunger. Treatment duration is based upon clinical response, but usually ranges from 90–270 days. (Label information; *ReBalance*®—Phoenix)

Monitoring

- CBC (including platelets): baseline and at least monthly during therapy
- GI adverse effects
- Clinical Efficacy: Improvement in neuro signs, CSF Western Blot test negative

Client Information

- Shake well before using and store at room temperature; see dosage information for instructions on proper administration
- Horse may develop worsening signs after beginning treatment, probably due to local inflammation from dying parasites
- Watch for signs that may indicate toxicity including depression, bleeding, bruising, bloody diarrhea, etc.; contact veterinarian if these occur

Chemistry/Synonyms

Pyrimethamine is an aminopyrimidine agent structurally related to trimethoprim. It occurs as an odorless, white, or almost white, crystalline powder or crystals. It is practically insoluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfadoxine and Pyrimethamine may also be known as *Fansidar*® and *ReBalance*®.

Storage/Stability

ReBalance® suspension should be stored at controlled room temperature (15–30°C) and protected from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sulfadiazine (as the sodium salt) 250 mg/mL and Pyrimethamine 12.5 mg/mL Oral Suspension in quart (946.4 mL) bottles; *ReBalance*® *Antiprotozoal Oral Suspension* (Phoenix); (Rx) Approved for use in horses; not for use in horses intended for human consumption.

HUMAN-LABELED PRODUCTS:

A related compound for humans is: Sulfadoxine & Pyrimethamine Tablets: 500 mg sulfadoxine & 25 mg pyrimethamine; *Fansidar*® (Roche); (Rx)

QUINACRINE HCL

(qwin-a-krin)

ANTIPROTOZOAL**Prescriber Highlights**

- ▶ Antiprotozoal that may be useful for treatment of *Giardia*, *Leishmania*, & *coccidia*. May improve clinical signs associated with giardial infection, but not eliminate infection
- ▶ Contraindications: Potentially, if hepatic dysfunction or pregnancy
- ▶ Adverse Effects: Yellowing of skin & urine color, (not of clinical importance); GI (anorexia, nausea, vomiting, diarrhea), abnormal behaviors (“fly biting”, agitation), pruritus, & fever. Potentially: Hypersensitivity, hepatopathy, aplastic anemia, corneal edema, & retinopathy.
- ▶ Availability an issue
- ▶ Potential teratogen
- ▶ Give with meals; have liquid available

Uses/Indications

While quinacrine has activity against a variety of protozoans and helminths, its use against all but *Giardia* and *Trichomonas* has been superseded by safer or more effective agents. In humans, quinacrine may be used for treatment of mild to moderate discoid lupus erythromatosis, transcutaneously as a sterilizing agent, or in powder form as an intrapleural sclerosing agent.

Pharmacology/Actions

Quinacrine’s mechanism of action for its antiprotozoal activity against *Giardia* is not understood, however, it does bind to DNA by intercalation to adjacent base pairs thereby inhibiting RNA transcription and translocation. Additionally, quinacrine interferes with electron transport and inhibits succinate oxidation and cholinesterase. Quinacrine binds to nucleoproteins that (in humans at least) can suppress lupus erythromatosis (LE) cell factor.

Pharmacokinetics

Quinacrine is absorbed well from the GI tract or after intrapleural administration. It is distributed throughout the body, but CSF levels are only 1–5% of those found in plasma. Drug is concentrated in the liver, spleen, lungs, and adrenals. It is relatively highly bound to plasma proteins in humans (80–90%). Quinacrine crosses the placenta, but only small amounts enter maternal milk.

Quinacrine is eliminated very slowly (half life in humans: 5–14 days). Quinacrine is slowly metabolized, but primarily eliminated by the kidneys; acidifying the urine will increase renal excretion somewhat. Significant amounts may be detected in urine up to 2 months after drug discontinuation.

Contraindications/Precautions/Warnings

In humans, quinacrine is relatively contraindicated in patients with psychotic disorders, psoriasis, or porphyria as it may exacerbate these conditions. Veterinary relevance is unknown. The drug should be used with extreme caution in patients with hepatic dysfunction.

Adverse Effects

In small animals, a yellowing of skin and urine color can occur, but is not of clinical importance (does not indicate jaundice). Additionally, gastrointestinal disturbances (anorexia, nausea, vomiting, diarrhea), abnormal behaviors (“fly biting”, agitation), pruritus, and fever have been noted.

Potentially hypersensitivity reactions, hepatopathy, aplastic anemia, corneal edema, and retinopathy could occur (all reported rarely in humans, primarily with high dose long-term use).

Reproductive/Nursing Safety

Quinacrine crosses the placenta and has been implicated in causing a case of renal agenesis and hydrocephalus in a human infant. In high doses, it has caused increased fetal death rates in rats. Weigh the potential benefits with the risks when considering use in pregnant animals.

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

Overdosage may be serious depending on the dose. In humans, a dose as low as 6.8 grams (administered intraduodenally) caused death. Clinical signs associated with acute toxicity include CNS excitation (including seizures), GI disturbances, vascular collapse, and cardiac arrhythmias. Treatment consists of gut emptying protocols, and supportive and symptomatic therapies. Urinary acidification with ammonium chloride and forced diuresis (with adequate fluid therapy) may be beneficial in enhancing urinary excretion of the drug.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving quinacrine HCl and may be of significance in veterinary patients:

- **ALCOHOL:** Quinacrine may cause a “disulfiram-reaction” if used with alcohol.
- **HEPATOTOXIC DRUGS:** Quinacrine concentrates in the liver and should be used with caution with hepatotoxic drugs (clinical significance unknown).
- **PRIMAQUINE:** Quinacrine increases the toxicity of primaquine (generally not used in veterinary medicine), and the two should not be used simultaneously.

Laboratory Considerations

- When urine is acidic, quinacrine can cause it to turn a deep yellow color. By causing an interfering fluorescence, quinacrine can cause falsely elevated values of **plasma and urine cortisol** values.

Doses

■ DOGS:

As a drug of second-choice in the treatment of Giardia or other susceptible protozoa:

- 6.6 mg/kg PO q12h for 5 days (Papich 1992), (Sherding and Johnson 1994), (Blagburn 2003b), (Blagburn 2005a)
- 9 mg/kg PO q24h for 6 days. (Lappin 2006b)

■ CATS:

- Giardia: 9 mg/kg PO once daily for 6 days; Coccidiosis: 10 mg/kg PO once daily for 5 days (Blagburn 2003b), (Blagburn 2005a)
- Giardia: 11 mg/kg PO q24h for 12 days (Lappin 2006b)
- Coccidiosis: 10 mg/kg PO once daily for 5 days (Greene and Watson 1998)

■ REPTILES:

- For hemoprotozoal infections: 19–100 mg/kg PO q48h (every other day) for 2–3 weeks (de la Navarre 2003b)

Monitoring

- Efficacy (fecal exams, reduction in diarrhea)
- Adverse effects

Client Information

- Quinacrine should preferably be given after meals with plenty of liquids available.
- Make sure clients understand the importance of compliance with directions and to watch for signs of adverse effects.

Chemistry/Synonyms

A synthetic acridine derivative anthelmintic, quinacrine HCl occurs as a bright yellow, odorless, crystalline powder having a bitter taste. It is sparingly soluble in water.

Quinacrine HCl may also be known as mepacrine HCl.

Storage/Stability

Tablets should be stored in tight, light-resistant containers at room temperature. Quinacrine is not stable in solution for any length of time; however, it may be crushed and mixed with foods to mask its very bitter taste.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

There currently are no quinacrine products being marketed in the USA. It may be available from compounding pharmacies.

QUINIDINE GLUCONATE QUINIDINE POLYGALACTURONATE QUINIDINE SULFATE

(*qwin-i-deen*) Quinidex®

ANTIARRHYTHMIC

Prescriber Highlights

- ▶ Antiarrhythmic agent used in small animals & horses
- ▶ Contraindications: Hypersensitivity, myasthenia gravis; complete AV block with an AV junctional or idioventricular pacemaker; intraventricular conduction defects; digitalis intoxication with associated arrhythmias or AV conduction disorders; aberrant ectopic impulses; or abnormal rhythms secondary to escape mechanisms
- ▶ Extreme Caution: Any form of AV block or if any clinical signs of digoxin toxicity are exhibited
- ▶ Caution: Uncorrected hypokalemia, hypoxia, & disorders or acid-base balance; hepatic or renal insufficiency
- ▶ Adverse Effects: DOGS: GI effects, weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex & QT intervals, AV block, & multiform ventricular tachycardias hypotension. HORSES: inappetence, depression, swelling of the nasal mucosa, ataxia, diarrhea, colic, hypotension & rarely, laminitis, paraphimosis & the development of urticarial wheals; cardiac arrhythmias including AV block, circulatory collapse & sudden death
- ▶ Consider monitoring blood levels
- ▶ Administer at evenly spaced intervals throughout the day/night
- ▶ GI upset may be decreased if administered with food
- ▶ Do not allow animal to chew or crush sustained-release oral dosage forms
- ▶ Many drug Interactions

Uses/Indications

Quinidine is used in small animal or equine medicine for the treatment of ventricular arrhythmias (VPCs, ventricular tachycardia), refractory supraventricular tachycardias, and supraventricular arrhythmias associated with anomalous conduction in Wolff-Parkinson-White (WPW) syndrome. Chronic use of quinidine for controlling ventricular arrhythmias and supraventricular tachycardia in dogs has diminished over the years as other drugs appear to be more effective. It is still used in dogs and horses to convert atrial fibrillation to sinus rhythm. Oral therapy is generally not used in cats.

Pharmacology/Actions

A class IA antiarrhythmic, quinidine has effects similar to that of procainamide. It depresses myocardial excitability, conduction velocity, and contractility. Quinidine will prolong the effective refractory period, which prevents the reentry phenomenon and increases conduction times. Quinidine also possesses anticholinergic activity which decreases vagal tone and may facilitate AV conduction.

Pharmacokinetics

After oral administration, quinidine salts are nearly completely absorbed from the GI, however, the actual amount that reaches the systemic circulation will be reduced due to the hepatic first-pass effect. The extended-release formulations of quinidine sulfate and gluconate, as well as the polygalacturonate tablets, are more slowly absorbed than the conventional tablets or capsules.

Quinidine is distributed rapidly to all body tissues except the brain. Protein binding varies from 82–92%. The reported volumes of distribution in various species are: horses \approx 15.1 L/kg; cattle \approx 3.8 L/kg; dogs \approx 2.9 L/kg; cats \approx 2.2 L/kg. Quinidine is distributed into milk and crosses the placenta.

Quinidine is metabolized in the liver, primarily by hydroxylation. Approximately 20% of a dose may be excreted unchanged in the urine within 24 hours after dosing. Serum half-lives reported in various species are: horses \approx 8.1 hours; cattle \approx 2.3 hours; dogs \approx 5.6 hours; cats \approx 1.9 hours; swine \approx 5.5 hours; goats \approx 0.9 hours. Acidic urine (pH <6) can increase renal excretion of quinidine and decrease its serum half-life.

Contraindications/Precautions/Warnings

Quinidine is generally contraindicated in patients who have demonstrated previous hypersensitivity reactions to it; myasthenia gravis; complete AV block with an AV junctional or idioventricular pacemaker; intraventricular conduction defects (especially with pronounced QRS widening); digitalis intoxication with associated arrhythmias or AV conduction disorders; aberrant ectopic impulses; or abnormal rhythms secondary to escape mechanisms. It should be used with extreme caution, if at all, in any form of AV block or if any clinical signs of digitalis toxicity are exhibited.

Quinidine should be used with caution in patients with uncorrected hypokalemia, hypoxia, and disorders or acid-base balance. Use cautiously in patients with hepatic or renal insufficiency as accumulation of the drug may result.

Adverse Effects

In dogs, gastrointestinal effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex and QT intervals, AV block, and multiform ventricular tachycardias.

Horses may exhibit inappetence and depression commonly after quinidine therapy but this does not necessarily indicate toxicity. Signs of toxicity include swelling of the nasal mucosa, ataxia, diarrhea, colic, hypotension and, rarely, laminitis, paraphimosis and the development of urticarial wheals. Urticaria or upper respiratory tract obstruction may be treated by discontinuing the drug and administering corticosteroids if necessary. If obstruction persists, nasotracheal tube placement or tracheostomy may be required. Horses may develop cardiac arrhythmias including AV block, circulatory collapse, and sudden death.

Patients exhibiting signs of toxicity or lack of response may be candidates for therapeutic serum monitoring. The therapeutic range is thought to be 2.5–5 mcg/mL in dogs. Toxic effects usually are not seen unless levels are >10 mcg/mL.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats*

or these drugs are safe if they are not administered when the animal is near term.)

Quinidine is excreted into maternal milk with a milk:serum ratio of approximately 0.71. Use caution when quinidine is administered to nursing patients. The American Academy of Pediatrics considers quinidine compatible with breastfeeding.

Overdosage/Acute Toxicity

Clinical signs of overdosage can include depression, hypotension, lethargy, confusion, seizures, vomiting, diarrhea, and oliguria. Cardiac signs may include depressed automaticity and conduction, or tachyarrhythmias. The CNS effects are often delayed after the onset of cardiovascular effects but may persist after the cardiovascular effects have begun to resolve.

If a recent oral ingestion, emptying of the gut and charcoal administration may be beneficial to remove any unabsorbed drug. IV fluids, plus metaraminol or norepinephrine, can be considered to treat hypotensive effects. A 1/6 molar intravenous infusion of sodium lactate may be used in an attempt to reduce the cardiotoxic effects of quinidine. Forced diuresis using fluids and diuretics along with reduction of urinary pH may enhance the renal excretion of the drug. Temporary cardiac pacing may be necessary should severe AV block occur. Hemodialysis will effectively remove quinidine, but peritoneal dialysis will not.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving quinidine and may be of significance in veterinary patients:

- **AMIODARONE:** May increase quinidine levels (significantly)
- **ANTACIDS:** May delay oral absorption; separate dosages
- **ANTIARRHYTHMIC AGENTS:** Use with caution with other antidysrhythmic agents, as additive cardiotoxic or other toxic effects may result
- **ANTICHOLINESTERASES** (e.g., **pyridostigmine**, **neostigmine**): Quinidine may antagonize the effects of anticholinesterases in patients with myasthenia gravis
- **CIMETIDINE:** Cimetidine may increase the levels of quinidine by inhibiting hepatic microsomal enzymes
- **CLARITHROMYCIN:** Increased risk for torsade de pointes
- **DIGOXIN:** Digoxin levels may increase considerably in patients stabilized on digoxin who receive quinidine. Some cardiologists recommend decreasing the digoxin dosage by 1/2 when adding quinidine. Therapeutic drug monitoring of both quinidine and digoxin may be warranted in these cases.
- **DILTIAZEM:** Possible decreased clearance; increased elimination half-life of quinidine
- **HYPOTENSIVE AGENTS:** Quinidine may potentiate the effects of other drugs having hypotensive effects
- **KETOCONAZOLE:** May reduce the metabolism of quinidine
- **NEUROMUSCULAR BLOCKING AGENTS:** Quinidine may increase the neuromuscular blocking effects of drugs like succinylcholine, tubocurarine, or atracurium
- **PHENOBARBITAL, PHENYTOIN:** May induce hepatic enzymes that metabolize quinidine thus reducing quinidine serum half-life by 50%
- **PHENOTHIAZINES:** Additive cardiac depressant effects may be seen
- **RESERPINE:** Additive cardiac depressant effects may be seen
- **RIFAMPIN:** May induce hepatic enzymes that metabolize quinidine thus reducing quinidine serum half-life by 50%

- **URINARY ACIDIFIERS** (e.g., **methionine**, **ammonium chloride**): Drugs that acidify the urine (may increase the excretion of quinidine and decrease serum level)
- **URINARY ALKALINIZERS** (**carbonic anhydrase inhibitors**, **thiazide diuretics**, **sodium bicarbonate**, **antacids**, etc.): Drugs that alkalinize the urine may decrease the excretion of quinidine, prolonging its half-life
- **VERAPAMIL**: Possible decreased clearance; increased elimination half-life of quinidine; increased risk for hypotension
- **WARFARIN**: Coumarin anticoagulants with quinidine may increase the likelihood of bleeding problems

Doses

■ DOGS:

- a) For VPC's or ventricular tachycardia:
Quinidine gluconate: 6.6–22 mg/kg IM q2–4h or q8–12h PO (delayed dosage forms).
Quinidine Sulfate: 6.6–22 mg/kg PO q6–8h; may be given initially q2h as a loading dose until arrhythmia is controlled or toxicity is induced (Ettinger 1989)
- b) 6–20 mg/kg IM q6h (loading dose 14–20 mg/kg); 6–16 mg/kg PO q6h; Sustained action oral preparations: 8–20 mg/kg PO q8h (Ware 2000)
- c) 6–16 mg/kg PO or IM q6h (q8h with sustained release products) (Fox 2003a)
- d) For conversion of atrial fib to sinus rhythm: Initially attempted with quinidine gluconate at 6–11 mg/kg IM q6h. Most dogs will convert in the first 24 hours of therapy. If rapid ventricular response occurs, may give either digoxin or a beta-blocker to slow rate of conduction across AV node. (Russell and Rush 1995)

■ CATS:

- a) 6–16 mg/kg IM or PO q8h (Ware 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) For atrial fib without signs of heart failure: Keep horse quiet during dosing stage. Monitor ECG either continuously or before each dose. Horses with recent onset (<7 days) or whom develop atrial fib during anesthesia: Quinidine gluconate 1.1–2.2 mg/kg IV every 10 minutes to a total dose of 8.8–11 mg/kg (or until conversion or toxicity develop).

For horses who have had atrial fib for >7 days: Give quinidine sulfate 22 mg/kg via NG tube every 2 hours for a total dose of 88–132 mg/kg (or until conversion or toxicity develop). If this fails to convert and no signs of toxicity are evident may continue at 22 mg/kg, PO q6h for an additional 2–4 or more days. Discontinue if QRS duration is >125% of baseline. Rapid SVT's (>100 BPM) or ventricular arrhythmias may necessitate specific antiarrhythmic therapy.

For V-Tach: Quinidine gluconate 0.5–2.2 mg/kg IV boluses every 10 minutes up to a total of 8.8–11 mg/kg (Mogg 1999)

- b) For atrial fibrillation in a horse without heart failure:
Oral (via NG tube) Dosing: give quinidine sulfate 22 mg/kg PO via nasogastric tube every two hours until cardioversion, toxic effects, or six doses have been given. If AF remains continue administration every 6 hours until cardioversion or adverse effects.

Alternate IV dosing method: 0.5–2.2 mg/kg IV bolus every 5–10 minutes to effect or until adverse effects seen. Maximum IV dose is 12mg/kg. Conversion of ventricular tachycardia has occurred with a single 0.5 mg/kg dose.

Monitor ECG throughout treatment. Heart rate in excess of 80 bpm, widening QRS complex >125% of baseline, or abnormal complexes are indicators to discontinue treatment.

Toxic effects are variable. Mild signs include nasal edema, and mild depression. More severe signs include marked ataxia, hypotension, colic, diarrhea, seizures, sustained tachycardia, syncope and sudden death. Adverse effects not necessarily dose dependent. Hypokalemia increases risk for torsades de pointes. Therapeutic levels 3–5 mcg/mL. (Kimberly and McGurrian 2006)

- c) For atrial fibrillation:

Oral (via NG tube) Dosing: give quinidine sulfate 22 mg/kg PO via nasogastric tube every two hours for 4–6 doses, followed by dosing q6h if needed for conversion. Withhold food for 12 hours prior to starting treatment to ensure maximum oral absorption. Quinidine dissolves poorly so 1–2 liters of water may be needed per dose. Oral ulcers can occur if attempting to administer by mouth. If nasal edema or urticaria occur, discontinue immediately. Heart rate in excess of 100 bpm, widening QRS complex >125% of baseline, ventricular arrhythmias or abnormal complexes are indicators to discontinue treatment or prolong dosing interval. Suggest monitoring levels. (Risberg 2005)

Monitoring

- ECG, continuous if possible
- Blood pressure, during IV administration
- Clinical signs of toxicity (see Adverse Reactions/Overdosage)
- Serum levels. Therapeutic serum levels are believed to range from 2–7 micrograms/mL. Levels >10 mcg/mL are considered toxic.

Client Information

- Oral products should be administered at evenly spaced intervals throughout the day/night. GI upset may be decreased if administered with food.
- Do not allow animal to chew or crush sustained-release oral dosage forms.
- Notify veterinarian if animal's condition deteriorates or signs of toxicity (e.g., vomiting, diarrhea, weakness, etc.) occur.

Chemistry/Synonyms

Used as an antiarrhythmic agent, quinidine is an alkaloid obtained from cinchona or related plants, or is prepared from quinine. It is available commercially in three separate salts: gluconate, polygalacturonate, or sulfate.

Quinidine gluconate occurs as a very bitter tasting, odorless, white powder. It is freely soluble in water and slightly soluble in alcohol. The injectable form has a pH of 5.5–7.

Quinidine polygalacturonate occurs as a bitter tasting, creamy white, amorphous powder. It is sparingly soluble in water and freely soluble in hot 40% alcohol.

Quinidine sulfate occurs as very bitter tasting, odorless, fine, needle-like, white crystals that may cohere in masses. One gram is soluble in approximately 100 mL of water or 10 mL of alcohol.

Quinidine Gluconate may also be known as: quinidinum gluconate, *Duraquin*®, *Quinaglute*®, *Quinalan*®, and *Quinate*®.

Quinidine Sulfate may also be known as: chinidini sulfas, chindinsulfate, chinidinum sulfuricum, or quinidini sulfas; many trade names are available.

Quinidine Polygalacturonate may also be known as: *Cardioquin*®, *Cardioquin*®, *Cardioquine*®, *Galactokin*®, *Naticardina*®, or *Neochinidin Ritmocar*®.

Storage/Stability/Compatibility

All quinidine salts darken upon exposure to light (acquire a brownish tint) and should be stored in light-resistant, well-closed containers. Use only colorless, clear solutions of quinidine gluconate for injection.

Quinidine gluconate injection is usually administered intramuscularly, but may be given very slowly (1 mL/minute) intravenously. It may be diluted by adding 10 to 40 mL of D₅W. Quinidine gluconate is reported to be physically **compatible** with bretylium tosylate, cimetidine HCl, and verapamil HCl. It is reportedly physically **incompatible** with alkalis and iodides.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Quinidine Sulfate (contains 83% anhydrous quinidine alkaloid) Tablets: 200 mg & 300 mg; generic; (Rx)

Quinidine Sulfate (contains 83% anhydrous quinidine alkaloid) Sustained-Release Tablets: 300 mg; generic; (Rx)

Quinidine Gluconate Sustained-release Tablets: 324 mg; generic; (Rx)

Quinidine Gluconate Injection: 80 mg/mL (50 mg/mL of quinidine base) in 10 mL multi-dose vials; generic (Lilly); (Rx)

RAMIPRIL

(ram-ih-prill) Altace®, Vasotop®

ANGIOTENSIN CONVERTING ENZYME (ACE) INHIBITOR**Prescriber Highlights**

- ▶ **ACE inhibitor used primarily as a vasodilator in the treatment of heart failure or hypertension; may be of benefit in the treatment of chronic renal failure or protein losing nephropathies**
- ▶ **Not as much information or experience available as some other ACE inhibitors (e.g., enalapril) in dogs or cats**
- ▶ **Contraindications: Hypersensitivity to ACE inhibitors**
- ▶ **Caution: Pregnancy, patients with hyponatremia, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE)**
- ▶ **Adverse Effects: Appears well tolerated in both dogs & cats. GI effects (anorexia, vomiting, diarrhea) possible; potentially: weakness, hypotension, & hyperkalemia**

Uses/Indications

Ramipril is a long-acting angiotensin converting enzyme (ACE) inhibitor that may be useful in treating heart failure or hypertension in dogs or cats. It is an approved product in the UK for treating heart failure in dogs. In cats, ramipril has been used for treating arterial hypertension. A recent study (MacDonald, Kittleson et al. 2006) did not show any significant benefit using ramipril in treating Maine Coon cats with hypertrophic cardiomyopathy without heart failure.

Like other ACE inhibitors, it may potentially be useful as adjunctive treatment in chronic renal failure and protein losing nephropathies. In dogs with moderate renal impairment (such as might be found with CHF), there is apparently no need to adjust ramipril dosage.

Pharmacology/Actions

Ramipril is a pro-drug that has little pharmacologic activity until converted into ramiprilat. Ramiprilat prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for ramiprilat than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased.

The cardiovascular effects of ramiprilat in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure with no change or decrease in heart rate. Increased cardiac index and output, stroke volume, and exercise tolerance also occur. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Pharmacokinetics

After oral administration to dogs, ramipril is rapidly converted via de-esterification into ramiprilat. Bioavailability of ramiprilat after a dose of 0.25 mg/kg per day of ramipril is about 6.7%. At this dose, ACE activity never exceeded 60% in either healthy dogs or those with experimentally induced renal dysfunction (GFR reduced 58%) (Lefebvre, Jeunesse et al. 2006).

After oral administration to cats with ramipril doses ranging from 0.125 mg/kg to 1 mg/kg once daily for 9 days, ramipril peak concentrations occurred in about 0.5 hours. Ramipril is rapidly converted into its active metabolite ramiprilat, which peaks at 1 hour post-administration. Repeated doses of 0.125 mg/kg inhibited serum ACE activity by 94% at maximum to 55% 24 hours post-dose. At a dose of 1 mg/kg, ACE activity was 97% inhibited at maximum, and 83% inhibited 24 hours post-dose (Coulet and Burgaud 2002).

When cats were administered radio-labeled ramipril orally, 85–89% of the radioactivity was recovered in the feces. It is unclear how much of this represents unabsorbed drug or absorbed parent compound/metabolites eliminated in the feces. Approximately 10% of administered drug was recovered in the urine. Excretion of radio-labeled compounds was complete by 168 hours after dosing.

Contraindications/Precautions/Warnings

The labeling for the UK product approved for dogs (Vasotop®) states that it should not be used in clinical cases of vascular stenosis (e.g., aortic stenosis), obstructive hypertrophic cardiomyopathy, or with potassium-sparing diuretics (see Drug Interactions).

Adverse Effects

While information is limited, ramipril appears to be well tolerated in dogs and cats. Gastrointestinal effects are probably the most likely adverse effects to be noted. Weakness, hypotension, or hyperkalemia are possible.

Reproductive/Nursing Safety

The labeling for the product approved in the UK (Vasotop®) suggests not using in bitches during pregnancy or lactation. Weigh the potential risks associated with using this medication (see human data below) in veterinary patients with the potential benefits of therapy. Dosages of up to 500 mg/kg/day did not impair fertility in

rats. While no teratogenic effects have been detected with ramipril in studies performed in mice, rats, rabbits, and cynomolgus monkeys, fetal risk is increased in humans.

If used in humans during the 2nd and 3rd trimesters increased rates of fetal death, neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios leading to fetal limb contractures, craniofacial deformation, and hypoplastic lung development were noted. In humans, ramipril has a “black box” warning regarding its use in pregnancy that states “When used in pregnancy during the second and third trimesters, angiotensin-converting enzyme (ACE) inhibitors can cause injury and even death to the developing fetus. When pregnancy is detected, ramipril should be discontinued as soon as possible.” For humans, the FDA categorizes ramipril as category **D** for use during the 2nd and 3rd trimesters of pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks*) and as category **C** for use during the first trimester of pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown whether ramipril (or ramiprilat) enters milk. Both the veterinary label (UK) and human label recommended not using the drug during nursing.

Overdosage/Acute Toxicity

In dogs, ramipril appears quite safe; dosages as high as 1 gram/kg induced only mild GI distress. Lethal doses in rats and mice were noted at 10–11 g/kg. No information was located on overdoses in cats. In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug’s long duration of action, prolonged monitoring and treatment may be required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ramipril and may be of significance in veterinary patients:

- **ASPIRIN:** Aspirin may potentially negate the decrease in systemic vascular resistance induced by ACE inhibitors. However, in one study in dogs using low-dose aspirin, hemodynamic effects of enalaprilat (active metabolite of enalapril, a related drug) were not affected.
- **ANTIDIABETIC AGENTS (insulin, oral agents):** Possible increased risk for hypoglycemia; enhanced monitoring recommended
- **DIURETICS (e.g., furosemide, hydrochlorothiazide):** Potential for increased hypotensive effects
- **DIURETICS, POTASSIUM SPARING (e.g., spironolactone, triamterene):** Increased hyperkalemic effects, enhanced monitoring of serum potassium
- **NSAIDS:** Potential for increased risk of renal dysfunction or hyperkalemia
- **POTASSIUM SUPPLEMENTS:** Increased risk for hyperkalemia

Laboratory Considerations

- ACE inhibitors may cause a reversible decrease in localization and excretion of **iodohippurate sodium I¹²³/I¹²⁴**, or **Technetium Tc⁹⁹ pententate** renal imaging in the affected kidney in patients with renal artery stenosis, which could lead to confusion in test interpretation

Doses

DOGS:

- a) For treatment of heart failure: Initially, 0.125 mg/kg PO once daily; depending on the severity of pulmonary congestion, dose may be increased to 0.25 mg/kg PO once daily (Label information; *Vasotop*®—Intervet UK)

CATS:

- a) For treatment of arterial hypertension: 0.125 mg/kg PO once daily (Graff and Herve 2003)

Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential, periodic
- Blood pressure (if treating hypertension or clinical signs associated with hypotension arise)

Client Information

- For this drug to be maximally effective it must be given once daily at about the same time each day
- Do not abruptly stop or reduce therapy without veterinarian’s approval
- Contact veterinarian if vomiting or diarrhea persist, are severe, or if animal’s condition deteriorates

Chemistry/Synonyms

Ramipril occurs as a white to almost white, crystalline powder that is sparingly soluble in water and freely soluble in methyl alcohol.

Ramipril may also be known as Hoe-498, ramiprilis, or ramiprilum. There are many international trade names, including: *Altace*®, *Cardase*®, *Delix*®, *Ramase*®, *Triatec*®, and *Tritace*®.

Storage/Stability

Capsules should be stored at room temperature (15–30°C) protected from light in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the USA; in the UK and in other European countries: Ramipril Tablets: 0.625 mg, 1.25 mg, 2.5 mg, & 5 mg; *Vasotop*® (Intervet); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

Ramipril Capsules: 1.25 mg, 2.5 mg, 5 mg, & 10 mg; *Altace*® (Monarch); (Rx)

RANITIDINE HCL

(rah-nit-a-deen) Zantac®

H₂ RECEPTOR ANTAGONIST; PROKINETIC

Prescriber Highlights

- H₂ receptor antagonist similar to cimetidine, but fewer drug interactions; used to reduce acid output in stomach; also has prokinetic activity
- Contraindications: Hypersensitivity. Caution: Geriatric patients, hepatic or renal insufficiency
- Adverse Effects: Rare. IV boluses may cause vomiting. Potentially: Mental confusion, agranulocytosis, & transient cardiac arrhythmias (too rapid IV injection). Pain at the injection site after IM administration.

Uses/Indications

In veterinary medicine, ranitidine has been used for the treatment and/or prophylaxis of gastric, abomasal, and duodenal ulcers, uremic gastritis, stress-related or drug-induced erosive gastritis, esophagitis, duodenal gastric reflux and esophageal reflux. It has also been employed to treat hypersecretory conditions associated with gastrinomas and systemic mastocytosis. Because of its effects on gastric motility, ranitidine may be useful in increasing gastric emptying, particularly when delayed gastric emptying is associated with gastric ulcer disease. Ranitidine may also be useful to stimulate colonic activity in cats via its prokinetic effects.

Pharmacology/Actions

At the H₂ receptors of the parietal cells, ranitidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, amino acids, pentagastrin, histamine, or insulin. Ranitidine is between 3–13 times more potent (on a molar basis) as cimetidine.

While ranitidine may cause gastric emptying times to be delayed, it more likely will stimulate GI motility by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors). Lower esophageal sphincter pressures may be increased by ranitidine. By decreasing the amount of gastric juice produced, ranitidine decreases the amount of pepsin secreted.

Ranitidine, unlike cimetidine, does not appear to have any appreciable effect on serum prolactin levels, although it may inhibit the release of vasopressin.

Pharmacokinetics

In dogs, the oral bioavailability is approximately 81%, serum half-life is 2.2 hours and volume of distribution 2.6 L/kg.

In horses, oral ranitidine has a bioavailability of about 27% in adults and 38% in foals. Peak levels after oral dosing occur in about 100 minutes in adults and 60 minutes in foals. Apparent volume of distribution is approximately 1.1 L/kg and 1.5 L/kg in adults and foals, respectively. Clearance in adults is approximately 10 mL/min/kg and 13.3 mL/min/kg in foals.

In humans, ranitidine is absorbed rapidly after oral administration, but undergoes extensive first-pass metabolism with a net systemic bioavailability of approximately 50%. Peak levels occur at about 2–3 hours after oral dosing. Food does not appreciably alter the extent of absorption or the peak serum levels attained.

Ranitidine is distributed widely throughout the body and is only 10–19% bound to plasma proteins. Ranitidine is distributed into human milk at levels 25–100% of those found in plasma.

Ranitidine is both excreted in the urine by the kidneys (via glomerular filtration and tubular secretion) and metabolized in the liver to inactive metabolites; accumulation of the drug can occur in patients with renal insufficiency. The serum half-life of ranitidine in humans averages 2–3 hours. The duration of action at usual doses is from 8–12 hours.

Contraindications/Precautions/Warnings

Ranitidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and possibly at reduced dosage in patients with diminished renal function. Ranitidine has caused increased serum ALT levels in humans receiving high, IV doses for longer than 5 days. The manufacturer recommends that with high dose, chronic therapy, serum ALT values be considered for monitoring.

Adverse Effects

Adverse effects appear to be very rare in animals at the dosages generally used. Potential adverse effects (documented in humans) that might be seen include mental confusion and headache. Rarely,

agranulocytosis may develop and, if given rapidly IV, transient cardiac arrhythmias may be seen. Pain at the injection site may be noted after IM administration. IV boluses have been associated with vomiting in small animals.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Ranitidine is excreted in human breast milk with milk:plasma ratios of approximately 5:1 to 12:1. The drug is not recommended to be used in nursing humans; use with caution in nursing veterinary patients.

Overdosage/Acute Toxicity

Clinical experience with ranitidine overdosage is limited. In laboratory animals, very high dosages (225 mg/kg/day) have been associated with muscular tremors, vomiting and rapid respirations. Single doses of 1 gram/kg in rodents did not cause death.

Treatment of overdoses in animals should be handled using standard protocols for oral ingestions of drugs; clinical signs may be treated symptomatically and supportively if necessary. Hemodialysis and peritoneal dialysis have been noted to remove ranitidine from the body.

Drug Interactions

Unlike cimetidine, ranitidine appears to have much less effect on the hepatic metabolism of drugs and is unlikely to cause clinically relevant drug interactions via this mechanism. The following drug interactions have either been reported or are theoretical in humans or animals receiving ranitidine and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Ranitidine (dose-dependent) may inhibit acetaminophen metabolism
- **ANTACIDS** (high doses): May decrease the absorption of ranitidine; give at separate times (2 hours apart) if used concurrently
- **KETOCONAZOLE, ITRACONAZOLE:** Absorption may be reduced secondary to increased gastric pH
- **METOPROLOL:** Ranitidine may increase metoprolol half-life, and peak levels
- **NIFEDIPINE:** Ranitidine may increase nifedipine AUC by 30%
- **PROPANTHELINE:** Delays the absorption but increases the peak serum level of ranitidine; relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine
- **VITAMIN B-12:** Long-term ranitidine use may reduce oral absorption of B-12

Laboratory Considerations

- Ranitidine may cause a false-positive **urine protein** reading when using *Multistix*®. The sulfosalicylic acid reagent is recommended for determining urine protein when the patient is concomitantly receiving ranitidine.

Doses

■ DOGS:

For esophagitis:

- a) 1–2 mg/kg PO twice daily (Watrous 1988)

For chronic gastritis:

- a) 0.5 mg/kg PO twice daily (Hall and Twedt 1988)

For ulcer disease:

- a) 0.5–2 mg/kg PO, IV or IM q8–12h (Haskins 2000)
- b) 2 mg/kg PO, IV q8h (Matz 1995)
- c) 1–2 mg/kg PO, IV, SC q12h (also used for esophagitis) (Sellon 2007b)
- d) 2 mg/kg PO, IV q12h (Waddell 2007a)

For gastrinoma:

- a) 1–2 mg/kg PO, SC, IV q8–12h (Zerbe and Washabau 2000)
- b) 0.5 mg/kg PO, IV or SC twice daily (Kay, Kruth, and Twedt 1988)

To treat hypergastrinemia secondary to chronic renal failure:

- a) 1–2 mg/kg PO twice daily (Morgan 1988)

To treat hyperhistaminemia secondary to mast cell tumors:

- a) 2 mg/kg q12h (Fox 1995)

As a prokinetic agent to stimulate gastric contractions:

- a) 1–2 mg/kg PO q12h (Hall and Washabau 2000)

■ CATS:

For ulcer disease/esophagitis:

- a) 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h (Matz 1995), (Johnson 1996)
- b) 1–2 mg/kg PO, IV, SC q12h (Sellon 2007b)
- c) 2 mg/kg PO, IV q12h (Waddell 2007a)

As a prokinetic agent to stimulate colonic motility:

- a) 1–2 mg/kg PO q8–12h (Washabau and Holt 2000)
- b) 1–2 mg/kg PO q12h (Scherk 2003b)

■ HORSES: (Note: ARCI UCGFS Class 5 Drug)

- a) 6.6 mg/kg PO q8h (Andrews and Nadeau 1999)
- b) Foals: 6.6 mg/kg IV q4h or 0.8–2.2 mg/kg IV four times a day; 5–10 mg/kg PO two to four times a day. (Wilkins 2004b)
- c) 1.5–2 mg/kg IV or IM q6–8h; 6.6 mg/kg PO q8h (Sanchez 2004a)

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in clinical signs, endoscopic examination, blood in feces, etc.

Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; symptoms may reoccur if dosages are missed.

Chemistry/Synonyms

An H₂ receptor antagonist, ranitidine HCl occurs as a white to pale-yellow granular substance with a bitter taste and a sulfur-like odor. The drug has pK_as of 8.2 and 2.7. One gram is approximately soluble in 1.5 mL of water or 6 mL of alcohol. The commercially available injection has a pH of 6.7–7.3.

Ranitidine HCl may also be known as: AH-19065, ranitidini hydrochloridum; many trade names are available.

Storage/Stability

Ranitidine tablets should be stored in tight, light-resistant containers at room temperature. The injectable product should be stored protected from light and at a temperature less than 30°C. A slight darkening of the injectable solution does not affect the potency of the drug.

Ranitidine injection is reportedly stable up to 48 hours when mixed with the commonly used IV solutions (including 5% sodium bicarbonate).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ranitidine HCl Tablets: 75 mg, 150 mg & 300 mg (as base); *Zantac*® (GlaxoSmithKline); (Rx); *Zantac*® 75 & -150 (Pfizer Consumer Healthcare); generic; (Rx or OTC)

Ranitidine HCl Effervescent Tablets: 25 mg & 150 mg (as base); *Zantac*® *EFFERdose* (GlaxoSmithKline); (Rx)

Ranitidine HCl Syrup: 15 mg/mL (as base) in 480 mL; *Zantac*® (GlaxoSmithKline); (Rx)

Ranitidine HCl Injection: 1 mg/mL (premixed) & 25 mg/mL in 50 mL (preservative free) plastic containers, 2 mL single-dose and 6 mL multi-dose vials; *Zantac*® (GlaxoSmithKline); generic (Bedford); (Rx)

RIFAMPIN

(rif-am-pin) Rifadin®, Rimactane®

ANTIMICROBIAL

Prescriber Highlights

- Antimicrobial with activity against a variety of microbes (*Rhodococcus*, mycobacteria, staphylococci); has some antifungal & antiviral activity as well.
- Contraindications: Hypersensitivity to it or other rifamycins
- Caution: Preexisting hepatic dysfunction (may need to reduce dosage)
- Adverse Effects: Uncommon; potentially rashes, GI distress, & increases in liver enzymes.
- Should not be used alone as resistance develops rapidly
- Preferably, give on an empty stomach
- May cause red/orange urine, tears, & sweat (harmless)
- Drug Interactions, lab interactions

Uses/Indications

The principle use of rifampin in veterinary medicine is in the treatment of *Rhodococcus equi* (*Corynebacterium equi*) infections (usually with erythromycin estolate) in young horses. It may also be useful to treat proliferative enteropathy caused by *Lawsonia intracellularis* in foals.

In small animals, the drug is sometimes used in combination with other antifungal agents (amphotericin B and 5-FC) in the treatment of histoplasmosis or aspergillosis with CNS involvement.

Pharmacology/Actions

Rifampin may act as either a bactericidal or bacteriostatic antimicrobial dependent upon the susceptibility of the organism and the concentration of the drug. Rifampin acts by inhibiting DNA-dependent RNA polymerase in susceptible organisms, thereby suppressing the initiation of chain formation for RNA synthesis. It does not inhibit the mammalian enzyme.

Rifampin is active against a variety of mycobacterium species and *Staphylococcus aureus*, *Neisseria*, *Haemophilus*, and *Rhodococcus equi* (*C. equi*). At very high levels, rifampin has activity against poxviruses, adenoviruses, and *Chlamydia trachomatis*. Rifampin has antifungal activity when combined with other antifungal agents.

Pharmacokinetics

After oral administration, rifampin is relatively well absorbed from the GI tract. Oral bioavailability is reportedly about 40–70% in horses and 37% in adult sheep. If food is given concurrently, peak plasma levels may be delayed and slightly reduced.

Rifampin is very lipophilic and readily penetrates most body tissues (including bone and prostate), cells and fluids (including CSF). It also penetrates abscesses and caseous material. Rifampin is 70–90% bound to serum proteins, is distributed into milk and crosses the placenta. Mean volume of distribution is approximately 0.9 L/kg in horses, and 1.3 L/kg in sheep.

Rifampin is metabolized in the liver to a deacetylated form that also has antibacterial activity. Both this metabolite and unchanged drug are excreted primarily in the bile, but up to 30% may be excreted in the urine. The parent drug is substantially reabsorbed in the gut, but the metabolite is not. Reported elimination half-lives for various species are: 6–8 hours (horses), 8 hours (dogs), 3–5 hours (sheep). Because rifampin can induce hepatic microsomal enzymes, elimination rates may increase with time.

Contraindications/Precautions/Warnings

Rifampin is contraindicated in patients hypersensitive to it or to other rifamycins. It should be used with caution in patients with preexisting hepatic dysfunction.

Adverse Effects

Rifampin can cause red-orange colored urine, tears, sweat, and saliva. There are no harmful consequences from this effect. In some species (e.g., humans) rashes, GI distress, and increases in liver enzymes may occur, particularly with long-term use.

Because resistance develops rapidly when rifampin is used alone, it should be used in combination with other effective antibiotics.

Adverse effects in horses are apparently rare, but when combined with erythromycin, mild diarrhea (self-limiting) to severe enterocolitis in foals and mares, hyperthermia, and acute respiratory distress can occur. Although not commercially available, intravenous rifampin has caused CNS depression, sweating, hemolysis, and anorexia in horses.

Reproductive/Nursing Safety

Rodents given high doses of rifampin 150–250 mg/kg/day resulted in some congenital malformations in offspring, but the drug has been used in pregnant women with no reported increases in teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Rifampin is excreted in maternal milk; use with caution in nursing veterinary patients.

Overdosage/Acute Toxicity

Clinical signs associated with overdosage of oral rifampin generally are extensions of the adverse effects outlined above (GI, orange-red coloring of fluids, and skin), but massive overdoses may cause hepatotoxicity.

There were 16 exposures to rifampin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 6 were dogs with 1 showing clinical signs and 8 were cats with 1 showing clinical signs. The remaining 2 reported cases were both equine showing no clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, and central nervous system depression. Common findings in cats recorded in decreasing frequency included edema of the face, erythema, injected mucous membranes, mydriasis and tachypnea.

Should a massive oral overdosage occur, the gut should be emptied following standard protocols. Liver enzymes should be monitored and supportive treatment initiated if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving rifampin and may be of significance in veterinary patients:

■ **FLUOROQUINOLONES:** *In vitro* antagonism has been reported when rifampin is used concurrently with fluoroquinolone antibiotics and concurrent use should be avoided

Because rifampin has been documented to induce hepatic microsomal enzymes, drugs that are metabolized by these enzymes may have their elimination half-lives shortened and serum levels decreased; drugs/classes that may be affected by this process include:

- **BARBITURATES**
- **BENZODIAZEPINES** (e.g., diazepam)
- **CHLORAMPHENICOL**
- **CORTICOSTEROIDS**
- **DAPSONE**
- **KETOCONAZOLE**
- **PROPRANOLOL**
- **QUINIDINE**
- **WARFARIN**

Laboratory Considerations

■ Microbiologic methods of assaying serum **folate** and **vitamin B₁₂** are interfered with by rifampin.

■ Rifampin can cause false-positive **BSP** (bromosulphophthalein, sulfobromophthalein) test results by inhibiting the hepatic uptake of the drug

Doses

Note: Because resistance develops rapidly when rifampin is used alone, it should be used in combination with other effective antibiotics.

■ DOGS:

- a) For combination therapy of atypical Mycobacteria infections; treatment of resistant Staph endocarditis (in combination with amoxicillin/clavulanate or trimethoprim/sulfa): 10–20 mg/kg PO q8–12h (Trepanier 1999)
- b) For CNS fungal infections (aspergillosis/histoplasmosis): Rifampin 10–20 mg/kg PO three times daily with amphotericin B and flucytosine (Schunk 1988)
- c) For actinomycosis: 10–20 mg/kg PO q12h PO (Hardie 1984)

■ CATS:

- a) For CNS fungal infections (aspergillosis/histoplasmosis): Rifampin 10–20 mg/kg PO three times daily with amphotericin B and flucytosine (Schunk 1988)

■ HORSES:

For treatment of *Rhodococcus equi* (*C. equi*) infections in foals:

- a) Rifampin 5 mg/kg PO two times daily with erythromycin 15–25 mg/kg, PO q12–24h. Conventional treatment, but erythromycin has numerous side effects including enterocolitis in foals and mares, hyperthermia, and acute respiratory distress. Clarithromycin may be superior. (Chaffin 2006b)
- b) Rifampin 5 mg/kg PO two times daily or 10 mg/kg PO once daily with erythromycin 25 mg/kg, PO q6–8h. Duration of therapy usually takes 4–9 weeks. (Giguere 2003b)

For susceptible infections in foals:

- a) For treatment of proliferative enteropathy caused by *Lawsonia intracellularis* in foals: Erythromycin estolate (25 mg/kg PO q6–8h) alone or in combination with rifampin: 10 mg/kg PO once daily for a minimum of 21 days (Lavoie and Drolet 2003)

■ BIRDS:

For treatment of mycobacteriosis:

- a) Rifampin (45 mg/kg PO once daily) in combination with ethambutol (30 mg/kg PO once daily) and one of the following: clofazimine (6 mg/kg PO once daily) or isoniazid (30 mg/kg PO once daily). (Pollock 2007a)

Monitoring

- Clinical efficacy
- For monitoring *C. equi* infections in foals and response to rifampin/erythromycin: Chest radiographs and plasma fibrinogen levels have been suggested as prognostic indicators when done after 1 week of therapy. (Hillidge and Zertuche 1987)
- Adverse effects: may consider liver function monitoring with long-term therapy.

Client Information

- Rifampin may cause urine and other secretions (tears, saliva, etc.) to turn red-orange in color; this is not abnormal
- Preferably give on an empty stomach
- May cause softening of stools in horses/foals

Chemistry/Synonyms

A semi-synthetic zwitterion derivative of rifamycin B, rifampin occurs as a red-brown, crystalline powder with a pK_a of 7.9. It is very slightly soluble in water and slightly soluble in alcohol.

Rifampin may also be known as: Ba-41166/E, L-5103, NSC-113926, rifaldazine, rifampicinum, rifamycin AMP; many trade names are available.

Storage/Stability

Rifampin capsules should be stored in tight, light-resistant containers, preferably at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Rifampin Capsules: 150 mg & 300 mg; *Rifadin*® (Aventis); *Rimactane*® (Novartis); generic; (Rx)

Rifampin Powder for Injection: 600 mg; *Rifadin*® (Aventis); (Rx)

ROMIFIDINE HCL

(roe-mif-ih-deen) Sedivet®

ALPHA-2 AGONIST SEDATIVE ANALGESIC

Prescriber Highlights

- Alpha-2 agonist with sedative, muscle relaxant & analgesic effects
- Indicated in USA for adult horses as a sedative & analgesic to facilitate handling, clinical examinations & procedures, minor surgical procedures, & as preanesthetic prior to the induction of general anesthesia
- Labeled in some European countries for use in dogs & cats; has been used extra-label in foals & cattle
- Adverse effects in HORSES include bradycardia (possibly profound), first- & second-degree atrioventricular heart block, sinus arrhythmias (dose dependent), initial hypertension followed by hypotension, ataxia, sweating, piloerection, salivation, muscle tremors, penile-relaxation, urination, swelling of face, lips & upper airways, stridor, decreased GI motility, flatulence & mild colic; anaphylaxis possible
- In DOGS & CATS, romifidine may cause bradycardia, cardiac arrhythmias, hypotension, transient hyperglycemia, & alterations in thermoregulation. Dogs may pant, salivate, vomit (less likely than in cats), & develop muscle twitching. Vomiting in cats may be a problem
- Adjust dosage if used with other CNS depressant drugs

Uses/Indications

Romifidine is an alpha-2 agonist with sedative, muscle relaxant and analgesic effects. It is indicated (in the USA) for use in adult horses as a sedative and analgesic to facilitate handling, clinical examinations and procedures, minor surgical procedures, and as a preanesthetic prior to the induction of general anesthesia.

In certain European countries, it is approved for use in dogs and cats as a sedative/preanesthetic.

Although not approved, romifidine has been used in cattle and foals.

Pharmacology/Actions

A potent alpha₂-adrenergic agonist, romifidine is classified as a sedative/analgesic with muscle relaxant properties. Alpha-2 receptors are found in the CNS and several tissues peripherally; both presynaptically and postsynaptically. In the CNS, the primary action is a feedback inhibition of norepinephrine release. Opioids and alpha-2 agonists may have synergistic analgesic effects.

Pharmacologic effects of romifidine include sedation, analgesia, and reduced catecholamine release from the CNS. Thermoregulatory mechanisms may be altered. Peripherally, an initial vasoconstrictive response occurs with increases in blood pressure. Within minutes a hypotensive phase occurs. Heart rate can significantly decrease secondary to a vagal response to hypertension. A second-degree atrioventricular block may also occur. Antimuscarinic agents can prevent bradycardia, but their use is controversial as they can potentially cause hypertension, increased myocardial oxygen demand, and reduced GI motility. Alpha-2 agonists can transiently slow duodenal motility and increase micturition in horses and can inhibit insulin release from pancreatic islet cells resulting in hyperglycemia. Other effects seen in horses in-

clude sweating, mydriasis, decreases in hematocrit, and increased uterine pressure in non-pregnant mares.

In horses, when compared with other alpha-2 agonists (xylazine, detomidine, medetomidine), romifidine does not appear to cause as much ataxia at sedative dosages and has the longest duration of sedation. Duration of analgesia is shorter than the duration of sedation.

Pharmacokinetics

Pharmacokinetic studies for romifidine in horses were not located.

In dogs and cats, bioavailability after IM administration is 86% and 95%, respectively. Bioavailability after subcutaneous injection in dogs is 92%. Peak levels after IM injection occur in approximately 50 minutes in dogs and 25 minutes in cats. After IV injection, volumes of distribution are about 3 L/kg in dogs, and 6 L/kg in cats. Romifidine is biotransformed in the liver. In dogs, about 80% of an administered dose is eliminated in the urine; 20% in the feces. Elimination half-lives are approximately 2 hours for dogs, 6 hours for cats.

Contraindications/Precautions/Warnings

Romifidine should not be used in animals hypersensitive to it or in combination with intravenous potentiated sulfonamides. The label states that this medication should not be used in horses with respiratory disease, hepatic or renal disease, or other systemic conditions of compromised health. It also states that the effects of this medication have not been evaluated in horses with colic, or in foals. Because of its effects on heart rhythm and blood pressure, use very cautiously in horses with preexisting cardiac conditions.

The manufacturer cautions that using with other sedatives, tranquilizers, or opioids may potentiate the adverse effects of romifidine and to avoid using epinephrine as it may potentiate the effects of alpha-2 agonists.

Although animals may appear to be deeply sedated, some may respond (kick, etc.) to external stimuli; use appropriate caution.

When used in dogs and cats, the label for *Romydis*® (Virbac—Ireland) states: “Animals should be restrained to prevent injury, ensure that animals have sufficient fluid intake, and if undergoing prolonged sedation, animals should be prevented from becoming hypothermic. Additionally, care should be taken when used in animals in poor health, suffering from respiratory distress, or in cases of cardiovascular, renal, hepatic or pancreatic disease.” Cats with pancreatitis should be closely monitored. Because dogs and, particularly, cats may vomit after receiving romifidine, the manufacturer recommends not feeding for at least 12 hours prior to use.

This medication can be absorbed through the skin and via oral routes. Persons administering the medication should handle it carefully and avoid self-exposure.

Adverse Effects

In horses, romifidine may cause bradycardia (possibly profound), first- and second-degree atrioventricular heart block, and sinus arrhythmias (dose dependent). Initially, hypertension may occur followed by hypotension. Other adverse effects can include: ataxia, sweating, piloerection, salivation, muscle tremors, penile-relaxation, urination (occurs about one hour after dose), swelling of face, lips and upper airways, stridor, decreased GI motility, flatulence and mild colic. There is a possibility that horses may react paradoxically (excitation) to romifidine. Rarely, anaphylactic reactions to alpha-2 agonists have been reported in horses.

In dogs and cats romifidine may cause bradycardia, cardiac arrhythmias, hypotension, transient hyperglycemia, and alterations in thermoregulation (body temperature may increase or decrease depending on ambient temperature). Dogs may pant, salivate, vomit (less likely than in cats), and develop muscle twitching.

In cats, vomiting associated with romifidine use can be seen and persist up to 24 hours after dosing. Pancreatitis has been noted in some cats receiving the drug repeatedly every 2 days for 6 days; dose related increases in BUN have been observed. Localized injection site reactions have occurred in cats receiving the medication intramuscularly.

Reproductive/Nursing Safety

The label for the US product states that the effects of this medication have not been evaluated in pregnant mares, horses intended for breeding, or foals.

The labeling for the equine and small animal products approved in Europe states that the drug is contraindicated in pregnant horses during the last month of pregnancy and during pregnancy in dogs and cats.

Overdosage/Acute Toxicity

Horses have received up to 600 mcg/kg (5X) in experimental studies. Signs exhibited included sinus bradycardia, 2nd degree heart block, occasional apnea and mild respiratory stridor, deep sedation, frequent urination, and sweating. No clinically significant alterations in blood gases, acid-base, hematological or chemical parameters were noted. If necessary, a reversal agent such as atipamezole (at a dose of 30–80 mcg/kg) or yohimbine may be used to reduce the duration and extent of adverse effects associated with acute toxicity.

Dogs have been administered doses of up to 1 mg/kg (approx 8–10X) IV daily for up to 4 weeks with no serious adverse effects reported.

Drug Interactions

- **INTRAVENOUS POTENTIATED SULFONAMIDES** (e.g., trimethoprim/sulfa): The manufacturer warns against using this agent with intravenous potentiated sulfonamides as fatal dysrhythmias may occur
- **OTHER ALPHA-2 AGONISTS** (e.g., xylazine, medetomidine, detomidine, clonidine and including epinephrine): Not recommended to be used together with romifidine as effects may be additive
- **PHENOTHIAZINES** (e.g., acepromazine): Severe hypotension can result

The following drug interactions have either been reported or are theoretical in humans receiving a similar alpha-2 agonist, dexmedetomidine and may be of significance in veterinary patients:

- **ANESTHETICS, OPIATES, SEDATIVE/HYPNOTICS:** Effects may be additive; dosage reduction of one or both agents may be required; potential for increased risk for arrhythmias when used in combination with thiopental, ketamine or halothane

Laboratory Considerations

- **ADP-induced platelet aggregation:** Can be inhibited in cats by medetomidine (a related alpha-2 agonist); not known if romifidine can have this effect

Doses

■ HORSES (adults):

- a) **For sedation and analgesia:** 40–120 mcg/kg IV slowly one time. This dose is equivalent to 0.4–1.2 mL per 100 kg (220 lb) body weight using the 1% (10 mg/mL) injection. Degree of sedation and analgesia is dose and time dependent. Onset of action occurs between 30 seconds to 5 minutes and gradually subsides during the next 2–4 hours. Duration of analgesia is shorter than the duration of sedation. See the package insert for expected onset and duration times for sedation and analgesia based upon dose.

As a preanesthetic: 100 mcg/kg as slow, single IV injection. Induce anesthesia after maximal sedation is achieved. Mild to moderate sedation occurs in 2–4 minutes. Anesthetic doses may need to be decreased to prevent an overdose as romifidine has anesthesia-sparing effects. (Label information; *Sedavet*®—B-I Vetmedica)

■ **DOGS:**

- a) **For sedation:** 40–120 mcg/kg IV, IM or SQ. IV administration causes sedation within approximately 5 minutes. With SC or IM injection sedation is delayed until about 30 minutes post-injection. Sedation depth is also lower than with IV injection. Atipamezole may be used to hasten recovery. A dose of 200 mcg/kg atipamezole IM will reverse a dose of 120 mcg/kg of romifidine.

As a preanesthetic: 40–120 mcg/kg IV, IM or SQ. Induce anesthesia (with propofol or thiopental) approximately 10 minutes after IV injection and 10–15 minutes after IM or SC injection. Label states to maintain anesthesia with halothane. (Label information; *Romydis*®—Virbac-Ireland)

- b) **As an analgesic adjunct:** 10–20 mcg/kg IM, SQ. May combine with an anticholinergic agent in exercise-tolerant patients free from heart disease. (Lamont and Tranquilli 2002)

■ **CATS:**

- a) **For sedation:** 200–400 mcg/kg IV or IM. An IM injection of 200 mcg/kg gives sedation in about 10 minutes and persists for about 60 minutes. IV administration gives a more rapid onset of action (5 minutes) and the duration is similar to IM. Atipamezole IM 30 minutes after IM romifidine injection may be used to hasten recovery. A dose of 400 mcg/kg atipamezole IM will reverse a dose of 400 mcg/kg of romifidine.

As a preanesthetic: 200 mcg/kg IM 10–15 minutes prior to giving ketamine at 10 mg/kg IM will provide surgical anesthesia for up to 30 minutes. Increasing the dose of romifidine to 400 mcg/kg will extend period of surgical anesthesia. A "top-up dose" of 50% of the initial doses of romifidine and ketamine can be used to prolong anesthesia. (Label information; *Romydis*®—Virbac-Ireland)

- b) **As an analgesic adjunct:** 20–40 mcg/kg IM, IV. May combine with an anticholinergic agent in exercise-tolerant patients free from heart disease. (Lamont and Tranquilli 2002)

■ **CATTLE:**

Note: Romifidine is not approved for use in cattle or other food-producing animals in the USA. For guidance with determining withdrawal times, contact FARAD (see Phone Numbers & Websites in the appendix for contact information).

- a) **For epidural anesthesia for paralumbar analgesia or laparotomy:** Romifidine 50 mcg/kg plus morphine 0.1 mg/kg. Duration of analgesia is 12 hours maximum. (Anderson 2006b)

Monitoring

- Level of sedation/analgesia
- Respiratory rate
- Heart rate/rhythm; blood pressure (during general anesthesia)
- Body temperature for longer procedures using higher dosages

Client Information

- This medication should only be administered by veterinary professionals
- If clients are involved with handling horses after they are dosed with romifidine, they should be warned that although the horse looks fully sedated it may respond defensively (e.g., kick) when stimulated

Chemistry/Synonyms

Romifidine HCl is an alpha-2 adrenoreceptor agonist that is structurally related to clonidine. It has a molecular weight of 258.1 and occurs as a crystalline, white, odorless substance that is soluble in water. Its chemical name is 2-(2-Bromo-7-fluoroanilino-)-2-imidazole or 2-Bromo-6-fluoro-N-(1-imidazolin-2yl)aniline.

Romifidine may also be known as: STH-2130, romifidiini, romifidin, romifidina, romifidinum, *Romidys*®, *Sedivet*®, and *Sedivan*®.

Storage/Stability

Romifidine HCl injection should be stored at controlled room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Romifidine HCl 1% (10 mg/mL) Injection; *Sedivet*® (B-I Vetmedica); (Rx). In the USA: Approved for use in horses not intended for human consumption. In the UK, slaughter withdrawal is 6 days for horses.

A small animal product, *Romidys*® (Virbac) containing 1 mg/mL is approved for use in dogs and cats in some European countries.

HUMAN-LABELED PRODUCTS: None

RONIDAZOLE

(roe-nid-ah-zole)

ANTIPROTOZOAL

Prescriber Highlights

- Nitroimidazole antibiotic/antiparasitic drug that appears to be useful in treating *Tritrichomonas foetus* infections in cats; also used for treating trichomonas infections in non-food birds
- Potentially carcinogenic; avoid human exposure
- Neurotoxicity (reversible): more likely at higher doses (50 mg/kg twice daily), but can occur at lower dosages as well; GI effects possible
- Many potential drug interactions
- Must be compounded from bulk powder (100%) & ideally, put in gelatin capsules

Uses/Indications

Ronidazole is a nitroimidazole antibiotic/antiparasitic drug that appears to be useful in treating *Tritrichomonas foetus* infections in cats. The drug is not commercially available in the USA and must be compounded from bulk powder by a compounding pharmacy. The drug is also used for treating *Trichomonas* infections in non-food animal birds.

Pharmacology/Actions

Ronidazole, like other 5-nitroimidazoles such as metronidazole is converted by hydrogenosomes (an organelle found in trichomonads) into polar autotoxic anion radicals. *T. foetus* infections in cats have been resistant to treatment by metronidazole, but ronidazole appears to have greater activity against the organism.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

Ronidazole should not be used in patients hypersensitive to it or other 5-nitroimidazoles (e.g., metronidazole).

The compound has been demonstrated to be carcinogenic in mice but not rats. While humans should avoid contact with this compound or with animal waste from treated patients, it can be safely compounded using a biological safety cabinet.

The FDA prohibits this drug for use in food animals.

Adverse Effects

Reversible neurotoxicity similar to that reported with metronidazole, has been reported in cats with ronidazole. Initial signs may include ataxia, nystagmus, or behavior changes. Should neurotoxicity be diagnosed, discontinue ronidazole, treat supportively, and if necessary, consider administering a benzodiazepine such as diazepam to competitively inhibit GABA receptors in the CNS. Incidence of neurotoxicity appears to be higher when using the 50 mg/kg twice daily dosage, but may occur at lower dosages as well. Potentially, gastrointestinal effects can occur (anorexia, vomiting). Ronidazole is very bitter and should be administered to cats in capsule form.

Ronidazole has been shown to increase the rate of benign mammary tumors in rats and increase the rates of benign and malignant pulmonary tumors in mice at dosages at or above 20 mg/kg/day.

Dogs given 30 mg/kg per day for two years (40 mg/kg/day the first month) showed some testicular toxicity (type not specified), but no tumors.

Reproductive/Nursing Safety

Safety of this compound during pregnancy is not established. Teratology studies have been performed in mice, rats, and rabbits. In rabbits given 30 mg/kg/day, no embryotoxicity occurred, but fetal weights were significantly decreased. Mice demonstrated no teratogenic effects at dosages of up to 200 mg/kg/day. Rats given up to 150 mg/kg/day demonstrated no embryotoxic effects, but at dosages of 200 mg/kg/day both maternal and fetal weights were decreased.

If this compound is to be used in pregnant cats, weigh the potential benefits of treating with the potential for adverse effects in the offspring and queen.

It is not known if ronidazole is distributed into milk and safety cannot be assured. Consider using milk replacer if treating nursing queens.

Overdosage/Acute Toxicity

No specific information was located. Cats receiving doses of 50 mg/kg twice daily appear to have greater incidences of neurotoxicity (see Adverse Reactions). If overdoses cause neurotoxicity, discontinue further therapy and treat supportively. Consider administering a GABA inhibitor such as diazepam, to competitively inhibit GABA receptors in the CNS.

Drug Interactions

In humans, the following drug interactions with metronidazole, a compound similar to ronidazole, have been reported or are theoretical and may be of significance in veterinary patients in patients receiving ronidazole:

- **ALCOHOL:** May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction
- **CIMETIDINE, KETOCONAZOLE:** May decrease the metabolism of ronidazole and increase the likelihood of dose-related side effects occurring
- **CYCLOSPORINE, TACROLIMUS (systemic):** Ronidazole may increase the serum levels of cyclosporine or tacrolimus

- **FLUOROURACIL (systemic):** Ronidazole may increase the serum levels of fluorouracil and increase risk for toxicity
- **LITHIUM:** Ronidazole may increase lithium serum levels and increase risk for lithium toxicity
- **OXYTETRACYCLINE:** Reportedly may antagonize the therapeutic effects of metronidazole (and presumably ronidazole)
- **PHENOBARBITAL, RIFAMPIN or PHENYTOIN:** May increase the metabolism of ronidazole thereby decreasing blood levels
- **WARFARIN:** Metronidazole (and potentially ronidazole), may prolong INR/PT in patients taking coumarin anticoagulants; avoid concurrent use if possible; otherwise intensify monitoring

Laboratory Considerations

- **AST, ALT, LDH (lactic dehydrogenase), Triglycerides, Hexokinase glucose:** A related compound, metronidazole can cause falsely decreased readings when determined using methods measuring decreases in ultraviolet absorbance when NADH is reduced to NAD. It is not known if ronidazole can also cause falsely decreased values.

Doses■ **CATS:**

- a) For treatment of *T. foetus* infections: 30 mg/kg PO twice daily for 14 days. (Gookin 2007) **Note:** Based on results of a published study of experimental *T. foetus* infection (Gookin, Copple et al. 2006) the author suggested using 30–50 mg/kg twice daily for 14 days, but subsequent experience has demonstrated a higher incidence of neurotoxicity at the higher dose and she now recommends treating at 30 mg/kg PO twice daily.

Monitoring

- Clinical efficacy (diarrhea improvement)
- Adverse effects (neurotoxicity, vomiting, anorexia)
- PCR testing (can be used to confirm infection, but negative results after treatment do not conclusively prove that infection has been eradicated)

Client Information

- Ronidazole must be given by mouth twice daily (approximately 12 hours apart) for 14 days for it to be effective. Do not skip doses.
- Store capsules in the freezer.
- This drug is considered a carcinogen. Do not open or crush capsules; give whole. It is recommended to wear disposable gloves when administering this medication.
- When cleaning litter box, wear disposable gloves; double bag feces and dispose in trash.
- Contact veterinarian immediately if cat shows signs of behavior changes, eyes moving back and forth (nystagmus), or has difficulty walking, climbing stairs, etc. (ataxia). These could be signs that drug toxicity is occurring.

Chemistry/Synonyms

Ronidazole is a 5-nitroimidazole compound that occurs as a white to yellowish-brown, odorless or almost odorless, bitter-tasting, powder. It is very slightly soluble in water or alcohol.

Ronidazole may also be known as ronidazol, ronidazolum, Belga®, Ridsol-S®, Ronida®, Ronivet®, Ronizol®, Turbosol®, Tricho Plus®, Trichocure®, or Trichorex®.

Storage/Stability

Compounded capsules should be stored in child-resistant, tight containers protected from light. Until further stability studies can be performed, capsules should be stored in the freezer.

Aqueous solutions are reportedly not very stable. It is recommended that fresh solutions using the 10% powder for addition to drinking water (used for pigeons) be freshly prepared every day.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None in the USA; a 10% ronidazole powder to be added to drinking water for treating *Trichomonas* infections in pigeons is available in some countries, but these products are unsuitable for use in cats due to the dosage required and the unpalatability (very bitter) of the powder and solution. Capsules prepared from 100% bulk powder for an individual feline patient should be obtained from a compounding pharmacy that can prepare the capsules in a bio-safety hood that will protect the compounder from drug exposure.

The FDA prohibits this drug for use in food animals.

HUMAN-LABELED PRODUCTS: None

S-ADENOSYL-METHIONINE**(S-AMe)****ADEMETHIONINE****(ess-ah-den-oh-seel meth-fe-oh-neen)****HEPATOPROTECTANT****Prescriber Highlights**

- ▶ “Nutraceutical” that can be used as an adjunctive treatment for liver disease (chronic hepatitis), osteoarthritis, or treatment of acetaminophen toxicity in small animals
- ▶ Well tolerated
- ▶ Not a regulated drug; choose products carefully

Uses/Indications

In small animal medicine, S-AMe is most commonly used as an adjunctive treatment for liver disease (chronic hepatitis, hepatic lipidos, cholangiohepatitis, feline triad disease, etc.). It may also be of benefit in osteoarthritis, treatment of acute hepatotoxin-induced liver toxicity (e.g., acetaminophen toxicity), and at-risk patients on long-term therapy using drugs with hepatotoxic potential.

In humans, S-AMe is being used as a treatment for depression, osteoarthritis, AIDS-related myopathy, intrahepatic cholestasis, liver disease, alcoholic liver cirrhosis, fibromyalgia, adult ADHD, Alzheimer's, migraines, etc.

Pharmacology/Actions

S-adenosyl-methionine (S-AMe) is an endogenous molecule synthesized by cells throughout the body. S-AMe is formed from the amino acid methionine and ATP, in conjunction with S-AMe synthetase enzyme (an enzyme manufactured in the liver, a rate-limiting step in the presence of liver compromise). S-AMe is an essential part of three major biochemical pathways: transmethylation, transsulfuration, and aminopropylation. Normal function of these pathways is especially vital to the liver as many metabolic reactions occur there. In the transmethylation pathway, S-AMe serves as a methyl donor (necessary for many substances and drugs to be activated and/or eliminated). Transmethylation is essential in phospholipid

synthesis important to cell membrane structure, fluidity, and function. In aminopropylation, S-AMe donates aminopropyl groups and is a source of polyamines. Aminopropylation is important in producing substances that have antiinflammatory effects, protein and DNA synthesis, and promoting cell replication and liver mass regeneration. In transsulfuration, S-AMe generates sulfur containing compounds important for conjugation reactions used in detoxification and as a precursor to glutathione (GSH). Glutathione is important in many metabolic processes and cell detoxification. The conversion of S-AMe to glutathione requires the presence of folate, cyanocobalamin (B₁₂), and pyridoxine (B₆). Normally, the liver produces ample S-AMe, but in liver disease or in the presence of hepatotoxic substances, endogenous conversion to glutathione may be deficient. Exogenous S-AMe has been shown to increase liver and red cell glutathione levels and/or prevent its depletion. S-AMe inhibits apoptosis secondary to alcohol or bile acids in hepatocytes.

In humans, the mechanism for its antidepressant effects are not well understood, but it apparently increases serotonin turnover and increases dopamine and norepinephrine levels. Neuroimaging studies in humans show that S-AMe affects the brain similarly to other antidepressant medications.

Pharmacokinetics

Oral bioavailability is dependent on the salt used to stabilize S-AMe. Oral bioavailability of the tosylate salt is reportedly 1% whereas the 1,4-butanedisulfonate form has a bioavailability of 5%. The presence of food in the gut can substantially reduce the amount of drug absorbed. Peak levels occur in 1–6 hours after oral dosing. Once absorbed, S-AMe enters the portal circulation and is primarily metabolized in the liver. In humans, 17% of a dose of radio-labeled S-AMe was recovered in the urine within 48 hours of dosing; 27% in the feces.

Contraindications/Precautions/Warnings

There are no apparent contraindications to the use of S-AMe.

Adverse Effects

Adverse effects appear to be minimal or non-existent in treated animals. Most studies in humans have shown adverse effects similar to that of placebo. Oral S-AMe in humans may cause anorexia, nausea, vomiting, diarrhea, flatulence, constipation, dry mouth, insomnia/nervousness, headache, sweating, and dizziness.

Reproductive/Nursing Safety

The safety of exogenous S-AMe has not been proven in pregnancy; use with caution. Limited studies in laboratory animals and in pregnant women with liver disease have not demonstrated any ill effects to mother or fetus.

It is unknown if S-AMe enters maternal milk.

Overdosage/Acute Toxicity

S-AMe appears to be quite safe. LD₅₀ in rodents exceeds 4.65 g/kg, and toxicity studies in dogs and cats at the usual prescribed dosages demonstrated no deleterious effects. In the case of an overdose, gastrointestinal effects may be observed, but unlikely to require treatment.

Drug Interactions

No interactions have been documented, but theoretically, concurrent use of S-AMe with **tramadol**, **meperidine**, **dextromethorphan**, **pentazocine**, monoamine oxidase inhibitors (**MAOIs**) including **selegiline**, selective serotonin reuptake inhibitors (**SSRIs**) such as **fluoxetine**, or other antidepressants (e.g., **amitriptyline**, **clomipramine**) could cause additive serotonergic effects.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses**■ DOGS & CATS:**

- Daily dose for animals with body weights of:
- up to 12 pounds (5.5 kg): one 90 mg tablet;
 - 12–25 pounds (5.5–11 kg): two 90 mg tablets (or one 225 mg tablet, if more convenient);
 - 25–35 pounds (11–16 kg): one 225 mg tablet;
 - 35–65 pounds (16–29.5 kg): two 225 mg tablets;
 - 65–90 pounds (29.5 kg–41 kg): three 225 mg tablets;
 - over 90 pounds (41 kg+): four 225 mg tablets.

Daily dosage may also be calculated based on 18 mg/kg of body weight and rounded to the closest tablet size or combination of sizes. Product should be given on an empty stomach, at least one hour before feeding. If giving more than one tablet, may divide total daily dosage and give twice daily. The number of tablets can be gradually reduced or may be increased at any time depending on the pet's needs. (Package information; *Denosyl*®—Nutramax)

For Liver Disease:

- a) For adjunctive treatment of chronic hepatitis: Dogs: 17–20 mg/kg or higher per day given on an empty stomach
Cats: 200 mg/day on an empty stomach.
Recommend using a reliable product with proven research in dogs and cats such as *Denosyl*®. (Center 2002)
- b) 20 mg/kg once daily (Willard 2006b)

Monitoring

- Clinical signs (appetite, activity, attitude)
- Liver enzymes, bilirubin, bile acids
- Liver biopsies
- Hepatic and erythrocyte glutathione levels (available at research institutions only at this time); may require 1–4 months before any changes in lab values are noted

Client Information

- Administer tablets to animal with an empty stomach, preferably at least one hour before feeding
- Keep tablets in original packaging until administration. Do not crush or split tablets

Chemistry/Synonyms

S-adenosyl-methionine (SAmE) is a naturally occurring molecule found throughout the body. Because pure SAmE is highly reactive and unstable, commercially available forms of SAmE are salt forms; sulfate, sulfate-p-toluenesulfonate (also known as tosylate), and butanedisulfonate salts can all be procured.

SAmE may also be known as: S-adenosyl-L-methionine, S-adenosylmethionine, SAM, SAM-e, adenosylmethionine, Sammy, methioninyl adenylate, *Donamet*®, *Gumbaral*®, *Isimer*®, *MoodLift*®, *SAmer*®, *Samyr*®, *Transmetil*®, and *Tunik*®.

Storage/Stability

Unless otherwise labeled, SAmE tablets should be stored at room temperature. Avoid conditions of high temperature or humidity. SAmE is inherently unstable in acidic or aqueous environments; store in tightly sealed, moisture-resistant containers.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None as a pharmaceutical. SAmE is considered a nutritional supplement by the FDA. No standards have been accepted for potency, purity, safety, or efficacy by regulatory bodies. Supplements are available from a wide variety of sources and dosage forms include tablets in a variety of concentrations. There are specific products marketed for use in animals, including *Denosyl*® (Nutramax) in 90 mg, 225 mg, & 425 mg enteric-coated, blister-packed tablets and *Zentonil*® (Vetoquinol) in 100 mg, 200 mg and 400 mg tablets. Bioequivalence between SAmE products is not assured. A combination product *Denamarin*® (Nutramax), containing SAmE and silybin (silymarin) is also labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

None as a pharmaceutical.

SALINE/HYPEROSMOTIC LAXATIVES MAGNESIUM SALTS PEG 3350 PRODUCTS

GoLYTELY®, Epsom Salts
LAXATIVES

Prescriber Highlights

- Saline/hyperosmotic agents for constipation, bowel “cleansing”, & to increase elimination of GI toxins
- Contraindications: PEG 3350 solutions are contraindicated in patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon. Saline cathartics should be used with extreme caution in patients with renal insufficiency, pre-existing water-balance or electrolyte abnormalities, or cardiac disease.
- Adverse Effects: Cramping, nausea possible
- If magnesium salts used chronically: Hypermagnesemia (muscle weakness, ECG changes & CNS effects)
- Drug Interactions

Uses/Indications

The saline laxatives are used for their cathartic action to relieve constipation. They are also used to reduce intestinal transit time thereby reducing the absorption of orally ingested toxicants. Polyethylene glycol 3350 balanced electrolyte solutions are used to evacuate the colon prior to intestinal examination or surgery.

Pharmacology/Actions

Although unproven, it is commonly believed that the hyperosmotic effect of the poorly absorbed magnesium cation causes water retention, stimulates stretch receptors and enhances peristalsis in the small intestine and colon. Recent data, however, suggests that magnesium ions may directly decrease transit times and increase cholecystokinin release.

Polyethylene glycol 3350 is a non-absorbable compound that acts as an osmotic agent. By adding sodium sulfate as the primary sodium source, sodium absorption is minimized. Other electrolytes (bicarbonate potassium and chloride) are also added so that no net

change occurs with either absorption or secretion of electrolytes or water in the gut.

Pharmacokinetics

When magnesium salts are administered, up to 30% of the magnesium dose of magnesium can be absorbed.

Generally, the onset of action of saline cathartics (characterized by a loose, watery stool) occurs in 3–12 hours after dosing in monogastric animals and within 18 hours in ruminants.

Contraindications/Precautions/Warnings

Saline cathartics are contraindicated for long-term or chronic use. Sodium containing laxatives are contraindicated in patients with congestive heart failure or congenital megacolon. PEG 3350 solutions are contraindicated in patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon. Saline cathartics should be used with extreme caution in patients with renal insufficiency, pre-existing water-balance or electrolyte abnormalities, or cardiac disease.

Adverse Effects

Except for possible cramping and nausea, adverse effects in otherwise healthy patients generally occur only with the saline cathartics with chronic use or overdoses. Hypermagnesemia manifested by muscle weakness, ECG changes and CNS effects can occur.

Reproductive/Nursing Safety

In humans, the FDA categorizes magnesium sulfate as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) Other saline or hyperosmolar cathartics should be safe to use in pregnancy when used infrequently.

Magnesium emulsions administered orally did not affect the stools of nursing infants, although magnesium content in breast milk was slightly elevated compared with untreated patients. In veterinary patients, it should be safe to use during nursing when used infrequently.

Overdosage/Acute Toxicity

Clinical signs of overdosage of magnesium containing laxatives are described above. Treatment should consist of monitoring and correcting any fluid imbalances that occur with parenteral fluids.

If hypermagnesemia occurs, furosemide may be used to enhance the renal excretion of the excess magnesium. Calcium has been suggested to help antagonize the CNS effects of magnesium.

Drug Interactions

All orally administered saline laxatives may alter the rate and extent of absorption of **other orally administered drugs** by decreasing intestinal transit times. The extent of these effects has not been well characterized for individual drugs, however.

■ **TETRACYCLINES:** Magnesium laxatives should not be administered with tetracycline products

Doses

■ DOGS:

Magnesium hydroxide (Milk of Magnesia) as a cathartic:

- a) 5–10 mL (Davis 1985a)
- b) 1–20 mL PO (Rossoff 1974)

Magnesium sulfate:

- a) 5–25 grams PO (Davis 1985a)
- b) 2–60 grams PO (Rossoff 1974)

Polyethylene Glycol-Electrolyte Solution:

- a) For colonic cleansing prior to colonoscopy using *Go-Lytely*®: Keep animal from food for 24–36 hours. On the evening prior to a morning colonoscopy (or the morning for an afternoon colonoscopy), give 60 mL/kg via orogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia. (Leib 2003), (Leib 2006)
- b) For colonic cleansing prior to colonoscopy using *Go-Lytely*®: 12–18 hours prior to colonoscopy give 25 mL/kg via orogastric tube three to five times, one hour apart. Give enema shortly after last *Go-Lytely*® dose and one to two hours prior to endoscopy procedure. (Richter 2003)
- c) For colonic cleansing prior to colonoscopy using *Go-Lytely*®: Withhold food for 18–24 hours. Give two doses of 20 mL/kg *Go-Lytely*® 4–6 hours apart the afternoon before an AM endoscopy. The morning of procedure, a warm-water enema is administered. (Jergens 2003)
- d) For mechanical bowel cleansing prior to (antibiotics and) colonic surgery: *Go-Lytely*® (or similar osmotic cathartic): 50–75 mL/kg by stomach tube or NE tube the evening prior to surgery. (Trepanier 2003)

■ CATS:

Magnesium hydroxide (Milk of Magnesia) as a cathartic:

- a) 2–6 mL (Davis 1985a)
- b) 1–5 mL PO (Rossoff 1974)

Magnesium sulfate:

- a) 2–5 grams PO (Davis 1985a), (Rossoff 1974)

Polyethylene Glycol-Electrolyte Solution:

- a) For colonic cleansing prior to colonoscopy using *Go-Lytely*®: Keep animal from food for 24–36 hours. On the evening prior to a morning colonoscopy (or the morning for an afternoon colonoscopy), give 60 mL/kg via nasogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia. Metoclopramide (0.2 mg/kg SC 15–20 minutes before the first *Go-Lytely*® dose is given to reduce vomiting. (Leib 2003), (Leib 2006)

■ CATTLE:

Magnesium sulfate (as a cathartic):

- a) 0.5–1 kg/500 kg orally (Whitlock 1986b)
- b) 1–2 gm/kg PO (Howard 1986)

Magnesium oxide:

- a) 0.5–1 kg/500 kg orally (Whitlock 1986b)

■ HORSES:

Magnesium sulfate (Epsom salt):

- a) 0.2 gm/kg diluted in 4 L of warm water administered via nasogastric tube. Administer only to well-hydrated animals (ideally in conjunction with IV fluid therapy). Do not treat longer than 3 days or there is an increased risk of enteritis or magnesium toxicity occurring. (Clark and Becht 1987)
- b) As a laxative: 1 g/kg PO every 1–2 days; in colic delay treatment until rehydrated (Moore 1999)
- c) To reduce absorption of toxicants and GI transit time: 500 gm (as a 20% solution) PO. If mineral oil has been used initially, give saline cathartic 30–45 minutes after mineral oil. (Oehme 1987)
- d) For cecal impactions: 1 g/kg dissolved in water dissolved in water and given via NG tube. Give with a balanced electrolyte solution IV to stimulate secretion into the dehydrated ingesta. (White 2005a)

■ SWINE:

Magnesium sulfate (as a cathartic):

- a) 1–2 gm/kg PO (Howard 1986)

■ BIRDS:

Magnesium sulfate:

- a) To act as a cathartic and reduce lead absorption: 0.5–1 gm/kg PO as a 5% solution in drinking water (McDonald 1986)

Monitoring

- Fluid and electrolyte status in susceptible patients, high doses, or chronic use
- Clinical efficacy

Client Information

- Do not give dosages greater than, or for periods longer than recommended by veterinarian
- Contact veterinarian if patient begins vomiting

Chemistry/Synonyms

Magnesium cation containing solutions of magnesium citrate, magnesium hydroxide, or magnesium sulfate act as saline laxatives. Magnesium citrate solutions contain 4.71 mEq of magnesium per 5 mL. Magnesium hydroxide contains 34.3 mEq of magnesium per gram and milk of magnesia contains 13.66 mEq per 5 mL. One gram of magnesium sulfate (Epsom salt) contains approximately 8.1 mEq of magnesium.

Polyethylene glycol 3350 is a non-absorbable compound that acts as an osmotic agent.

Storage/Stability

Magnesium citrate solutions should be stored at 2–30°C. Store milk of magnesia at temperatures less than 35°C, but do not freeze. PEG 3350 reconstituted (from powder by the pharmacy, client, clinic, etc.) solutions should be kept refrigerated and used within 24 hours.

Dosage Forms/Regulatory Status

Saline cathartic products have apparently not been formally approved for use in domestic animals. They are available without prescription (OTC). PEG 3350 products are available only by prescription and are approved for use in humans.

VETERINARY-LABELED PRODUCTS: None located

HUMAN-LABELED PRODUCTS:

Saline Laxatives (not an inclusive list):

Magnesium Hydroxide Suspension (Milk of Magnesia): equiv. to 30 mL milk of magnesia in 100 mL, 400 mL & UD 10 mL; magnesium hydroxide 160 mg/mL & 80 mg/mL in 180 mL, 240 mL, 360 mL, 400 mL, 480 mL, 780 mL, UD 30 mL; *Milk of Magnesia Concentrated*® (Roxane); *Phillips'® Milk of Magnesia* and *Phillips'® Milk of Magnesia Concentrated* (Bayer); generic; (OTC)

Magnesium Sulfate (Epsom Salt) Granules: in 120 g, 1lb and 4lbs; generic; (OTC)

Hyperosmotic Laxatives (not an inclusive list):

Polyethylene Glycol-Electrolyte Solution:

OCL® Solution (Abbott); (Rx) Oral Solution in 1500 mL: 146 mg sodium chloride, 168 mg sodium bicarbonate, 1.29 g sodium sulfate decahydrate, 75 mg potassium chloride, 6 grams PEG-3350 and 30 mg polysorbate—80/100 mL

CoLyte® (Schwarz Pharma); (Rx); 1 gallon of Powder for Oral Solution in bottles: 227.1 g PEG 3350, 5.53 gm sodium chloride, 6.36 gm sodium bicarbonate, 21.5 gm sodium sulfate, 2.82 gm potassium

chloride; 4L of solution: 240 g PEG 3350, 22.72 g sodium sulfate, 6.72 g sodium bicarbonate, 5.84 g NaCl, 2.98 g KCl

GoLYTELY® (Braintree Labs); (Rx); Powder for Oral Solution in jugs: 5.86 gm sodium chloride, 6.74 gm sodium bicarbonate, 22.74 gm sodium sulfate, 2.97 gm potassium chloride, 236 gm PEG 3350; Packets: 227.1 g PEG 3350, 21.5 g sodium sulfate, 6.36 g sodium bicarbonate, 5.53 g NaCl, 2.82 g KCl

NuLyte® (Braintree Labs); *TriLyte®* (Schwarz Pharma); (Rx); Powder for Reconstitution in 4 L jugs: 420 g PEG 3350, 5.72 g sodium bicarbonate, 11.2 g NaCl, 1.48 g KCl

MoviPrep® (Salix); (Rx); Powder for Reconstitution in pouches: 100 g PEG 3350, 7.5 g sodium sulfate, 2.691 g NaCl, 1.015 KCl.

SELAMECTIN

(sell-a-mek-tin) Revolution®

AVERMECTIN (TOPICAL) ANTIPARASITIC

Prescriber Highlights

- Topical avermectin antiparasiticide approved for multiple indications in dogs & cats
- Applied monthly (usually; some indications one time dosing)
- Adverse effect profile appears minimal

Uses/Indications

Topical selamectin (*Revolution®*—Pfizer) is indicated for flea infestations (*Ctenocephalides felis*), prevention of heartworm disease (*Dirofilaria immitis*), and for ear mites (*Otodectes cynotis*) in both dogs and cats. Additionally in dogs, it is indicated for sarcoptic mange (*Sarcoptes scabiei*), and tick infestations (*Dermacentor variabilis*). In cats: hookworm (*Ancylostoma tubaeforme*) and roundworm (*Toxocara cati*).

The product (*Revolution®*) is labeled as not effective against either adult heartworms or clearing circulating microfilaria, but it possibly may have some efficacy with prolonged, continuous administration (Atkins 2007b).

Pharmacology/Actions

Like other compounds in its class, selamectin is believed to act by enhancing chloride permeability or enhancing the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, it causes paralysis of the parasite and eventual death. As liver flukes and tapeworms do not use GABA as a peripheral nerve transmitter, selamectin would probably be ineffective against these parasites.

Pharmacokinetics

After topical administration to dogs, about 5% of the drug is bioavailable and peak plasma levels occur about 3 days later. Elimination half-life after topical administration is about 11 days.

After topical administration to cats, about 75% of the drug is bioavailable and peak plasma levels occur about 15 hours later. Elimination half-life after topical administration is about 8 days. In cats, bioavailability is about 75% and peak levels may be 64 times those in dogs.

The persistence of the drug in the body is believed to be due to the drug forming reservoirs in skin sebaceous glands. It is secreted into the intestine to kill susceptible endoparasites in cats.

Contraindications/Precautions/Warnings

The manufacturer recommends caution when using in sick, underweight, or debilitated dogs or cats. It is not recommended for use in animals under 6 weeks of age. At labeled doses of selamectin, dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc “white feet”) should tolerate the medication, but use cautiously.

Adverse Effects

In field trials (limited numbers of animals) adverse effects were rare. Approximately 1% of cats showed a transient, localized alopecia at the area of administration. Other effects reported (< or = 0.5% incidence) include diarrhea, vomiting, muscle tremors, anorexia, pruritus/urticaria, erythema, lethargy, salivation and tachypnea. Very rarely, seizures and ataxia have been reported in dogs.

Reproductive/Nursing Safety

Selamectin appears to be safe to use in pregnant or lactating dogs or cats.

Overdosage/Acute Toxicity

Dogs: Oral overdoses of up to 15 mg/kg did not cause adverse effects (except for ataxia in one avermectin sensitive collie). Topical overdoses (10x) to puppies caused no adverse effects; topical overdoses to avermectin-sensitive Collies caused salivation.

Cats: Oral ingestion may cause salivation and vomiting. Topical overdoses of up to 10x caused no observable adverse effects.

There were 218 exposures to selamectin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.asPCA.org) during 2005–2006. In these cases 125 were dogs with 4 showing clinical signs and 86 cases were cats with 15 showing clinical signs. The remaining 7 cases consisted of 5 ferrets and 2 lagomorphs none of which had clinical signs. Common findings in dogs recorded in decreasing frequency included hypersalivation, agitation, diarrhea, edema of the face and hyperactivity. Common findings in cats recorded in decreasing frequency included vomiting, anorexia, hyperesthesia, hyperthermia and mydriasis.

Drug Interactions

None documented, but caution is advised if using other drugs that can inhibit **p-glycoprotein**. Those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc “white feet”) should probably not receive selamectin with the following drugs, unless tested “normal”: Drugs and drug classes involved include:

- AMIODARONE
- CARVEDILOL
- CLARITHROMYCIN
- CYCLOSPORINE
- DILTIAZEM
- ERYTHROMYCIN
- ITRACONAZOLE
- KETOCONAZOLE
- QUINIDINE
- SPIRONOLACTONE
- TAMOXIFEN
- VERAPAMIL

Laboratory Considerations

None reported.

Doses

■ DOGS:

For prophylaxis and treatment of dirofilariasis, it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information

- a) The recommended topical dose is 6 mg/kg. Dosing frequency: Heartworm prevention, flea control = monthly; Ticks = monthly (if heavy infestations, may repeat 2 weeks after the first dose); Ear Mites, Sarcoptes = once, repeat in one month if necessary. See the package for specific instructions on administration technique. (Label information; *Revolution*®—Pfizer)

■ CATS:

- a) The recommended topical dose is 6 mg/kg. Dosing frequency: Heartworm prevention, flea control = monthly; Ear Mites = once, repeat in one month if necessary. Hookworms, Roundworms = once. See the package for specific instructions on administration technique. (Label information; *Revolution*®—Pfizer)

■ FERRETS:

- a) For heartworm prevention: 18 mg/kg topically every 30 days. (Johnson 2006c)

■ RABBITS:

- a) For ear mites (*P. Cunuculi*): 6–18 mg/kg topically (McTier, Hair et al. 2003)

Monitoring

- Clinical efficacy
- Owner compliance with treatment regimen

Client Information

- Follow label directions for administration technique; do not massage into skin, and do not apply if hair coat is wet. Because the product contains alcohol, do not apply to broken skin.
- Avoid contact with animal while the application site is wet.
- Wait two hours or more after applying to bathe the animal (or allow to go swimming).
- Avoid getting the product on human skin; if contact occurs, wash off immediately. Dispose of tubes in regular household refuse.
- Do not expose to flame as the product is flammable.

Chemistry/Synonyms

A semi-synthetic avermectin, selamectin is commercially available as a colorless to yellow solution (flammable).

Selamectin may also be known as UK-124114, or *Revolution*®.

Storage/Stability

The commercially available solution should be stored below 30°C (86°F). Keep away from flame or other igniters.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Selamectin Topical Solution for Cats; *Revolution*® (Pfizer); (Rx):

Up to 5 lbs in wt, Pkg. Color: mauve. 15 mg/tube. Tube volume: 0.25 mL

5.1–15 lbs in wt, Pkg. Color: blue. 45 mg/tube. Tube volume: 0.75 mL

Selamectin Topical Solution for Dogs; Revolution® (Pfizer); (Rx)

Up to 5 lbs in wt, Pkg. Color: mauve. 15 mg/tube. Tube volume: 0.25 mL

5.1–10 lbs in wt, Pkg. Color: purple. 30 mg/tube. Tube volume: 0.25 mL

10.1–20 lbs in wt, Pkg. Color: brown. 60 mg/tube. Tube volume: 0.5 mL

20.1–40 lbs in wt, Pkg. Color: red. 120 mg/tube. Tube volume: 1 mL

40.1–85 lbs in wt, Pkg. Color: teal. 240 mg/tube. Tube volume: 2 mL

85.1–130 lbs in wt, Pkg. Color: plum. One 120 mg tube and one 240 mg tube. Total volume: 3 mL

HUMAN-LABELED PRODUCTS: None

SELEGILINE HCL L-DEPRENYL

(se-*le*-ji-leen) Anipryl®, Eldepryl®

MONAMINE OXIDASE INHIBITOR

Prescriber Highlights

- ▶ **MAO-B inhibitor that may be useful for canine cognitive dysfunction syndrome or Cushing's (efficacy in doubt for Cushing's)**
- ▶ **Contraindications: Hypersensitivity to it. May be contraindicated in patients receiving opiates**
- ▶ **Adverse Effects: Vomiting & diarrhea; CNS effects manifested by restlessness, repetitive movements, or lethargy; salivation & anorexia. Diminished hearing/deafness, pruritus, licking, shivers/trembles/shakes possible**
- ▶ **Drug Interactions**

Uses/Indications

Selegiline is approved for use in dogs for the treatment of Cushing's disease and for Canine Cognitive Dysfunction (so-called "old dog dementia"). Its use for Cushing's disease is somewhat controversial as clinical studies evaluating its efficacy have shown disappointing results. In humans, selegiline's primary indication is for the adjunctive treatment of Parkinson's disease.

Pharmacology/Actions

Selegiline's mechanism of action for treatment of Cushing's disease (pituitary dependent hyperadrenocorticism—PDH) is complex; a somewhat simplified explanation follows: In the hypothalamus, corticotropin-releasing hormone (CRH) acts to stimulate the production of ACTH in the pituitary and dopamine acts to inhibit the release of ACTH. As dogs age, there is a tendency for a decrease in dopamine production that can contribute to the development of PDH.

As dopamine is metabolized by monamine oxidase-B (MAO-B) and selegiline inhibits MAO-B, dopamine levels can be increased at receptor sites after selegiline administration. In theory, this allows the levels of dopamine and CRH to be in balance in the hypothalamus, thereby reducing the amount of ACTH produced and ultimately, cortisol.

While selegiline is labeled as a MAO-B inhibitor, at higher than labeled dosages, the drug loses its MAO-B specificity and also inhibits MAO-A. Two of three metabolites of selegiline are amphetamine and methamphetamine that may contribute to both the efficacy and the adverse effects of the drug.

Pharmacokinetics

There is only limited information on the pharmacokinetics of selegiline in dogs. A study done in 4 dogs showed that selegiline was absorbed rapidly and had an absolute bioavailability of about 10%. The volume of distribution of the central compartment was measured at approximately 7 L/kg. Terminal half-life was about one hour.

In humans, selegiline pharmacokinetics have wide interpatient variability. The drug has a high first pass effect where extensive metabolism to L-desmethyloselegiline, methylamphetamine, and L-amphetamine occur. Each of these metabolites is active. While L-desmethyloselegiline does inhibit MAO-B, the others do not, but they are CNS stimulants. The drug is excreted in the urine, primarily as conjugated and unconjugated metabolites.

Contraindications/Precautions/Warnings

Selegiline is contraindicated in patients known to be hypersensitive to it. In human patients, it is contraindicated in patients receiving meperidine and possibly with other opioids as well.

The manufacturer cautions to perform appropriate diagnostic tests to confirm the diagnosis before starting therapy and not to attempt to treat hyperadrenocorticism not of pituitary origin.

Adverse Effects

Adverse reports reported thus far in dogs include, vomiting, diarrhea, CNS effects manifested by restlessness, repetitive movements or lethargy, salivation, and anorexia. Should GI effects be a problem, discontinue the drug for a few days and restart at a lower dose. Diminished hearing/deafness, pruritus, licking, shivers/trembles/shakes have also been reported. The manufacturer advises to observe animals carefully for atypical responses.

Adverse effects that have been reported in human patients include nausea (10%), hallucinations, confusion, depression, loss of balance, insomnia, and hypersexuality. These effects are noted because of their "subjective" nature and they could help explain untoward behavioral changes in canine patients should they occur.

Because selegiline could potentially be abused by humans, veterinarians should be alert for drug "shoppers." Selegiline is classified by the Association of Racing Commissioners International (ARCI) as a class 2 agent (high abuse potential in racing horses).

Reproductive/Nursing Safety

Safety of selegiline in pregnant, breeding or lactating animals has not been established. Rat studies have not demonstrated overt teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether selegiline is excreted in maternal milk.

Overdosage/Acute Toxicity

Oral LD₅₀ in laboratory animals was approximately 200–445 mg/kg. In limited data, dogs receiving 3x dosages showed signs of decreased weight, salivation, decreased pupillary response, panting, stereotypic behaviors and decreased skin elasticity (dehydration). Overdoses, if severe, should be treated with appropriate gut emptying and supportive treatments.

Drug Interactions

Evaluating the potential for drug interactions for selegiline in dogs is problematic. There are a plethora of significant interactions with monamine oxidase inhibitors in humans for selegiline, but because there are significant species differences in quantities and locations of MOA-A and B and selegiline's effects at various dosages on these

enzymes, they may not apply to dogs. However, the following drug interactions are some of the more significant interactions reported or are theoretical in humans or animals receiving selegiline and potentially could be of significance in veterinary patients; caution is advised particularly if using selegiline at higher than labeled dosages:

- **AMITRAZ:** The manufacturer recommends not using selegiline concurrently with amitraz (*Mitaban*®) in dogs
- **BUPROPION:** Potential for serotonin syndrome
- **EPHEDRINE:** The manufacturer recommends not using selegiline concurrently with ephedrine in dogs
- **MEPERIDINE:** In humans, severe agitation, hallucinations and death have occurred in some patients receiving meperidine and an MAO inhibitor. Until the data can be clarified, it is recommended not to use selegiline and meperidine together. A separation of two weeks has been recommended. Other opioids (e.g., morphine) should be safer, but use with extreme caution, if at all.
- **PHENYLPROPANOLAMINE, PSEUDOEPHEDRINE:** Increased risk for hypertension, hyperpyrexia
- **SSRI'S** (e.g., **fluoxetine**): Potentially, the so-called serotonin syndrome could occur if selegiline is used concurrently with selective serotonin reuptake inhibitors (SSRIs);
- **TRAMADOL:** Use contraindicated in humans; serotonin syndrome, nausea, vomiting, cardiovascular collapse
- **TRICYCLIC & TETRACYCLIC ANTIDEPRESSANTS** (**clomipramine, amitriptyline**, etc.): Potentially, the so-called serotonin syndrome could occur if selegiline is used concurrently with these agents and use together is not advised at this time; a 2-week separation between these compounds and selegiline is recommended.

Doses

■ DOGS:

For Cushing's disease:

- a) 1 mg/kg PO in the AM (with food as needed); Reevaluate clinically over next 2 mos.; if no improvement, may increase to 2 mg/kg once daily; if no improvement or signs increase, reevaluate diagnosis or consider alternate treatment (Package Insert; *Anipryl*®—Pfizer).

For Canine Cognitive Dysfunction:

- a) 0.5–1 mg/kg, PO once daily, preferably in the AM. Initially, dose to the nearest whole tablet; adjustments should then be made based upon response and tolerance to the drug (Package Insert; *Anipryl*®—Pfizer).
- b) 0.5–1 mg/kg PO once daily (give with food) (Hoskins 1999)

Monitoring

- Clinical efficacy
- Adverse effects. No correlation between low dose dexamethasone suppression test results and clinical efficacy of the drug. The manufacturer recommends physical exam and history as the primary methods to measure response to therapy.

Client Information

- Keep this and all medications out of reach of children
- Have clients monitor closely for adverse effects
- Clients should be advised on the importance of complying with the dosing recommendations to adequately evaluate therapeutic response to the drug

Chemistry/Synonyms

Selegiline HCl, also commonly called l-deprenyl, occurs as a white to off-white crystalline powder that is freely soluble in water. It has a pKa of 7.5.

Selegiline HCl may also be known as: deprenyl, L-deprenyl, selegilini hydrochloridum; many trade names are available.

Storage/Stability

Commercially available veterinary tablets should be stored at controlled room temperature 20–25°C (68–77°F). The commercially available human-labeled tablets and capsules are recommended to be stored from 15–30°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Selegiline HCl Oral Tablets: 2 mg, 5 mg, 10 mg, 15 mg, 30 mg in blister-packs of 30 tablets; *Anipryl*® (Pfizer); (Rx). Approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Selegiline HCl Tablets and Capsules: 1.25 mg (orally disintegrating) & 5 mg; *Eldepryl*® (Somerset); *Carbex*® (Du Pont Pharma); *Zelapar*® (Valeant Pharmaceuticals); generic tablets; (Rx)

Selegiline HCl Transdermal System: 6 mg/24 h (20 mg/20 cm²); 9 mg/24 h (30 mg/30 cm²) & 12 mg/25 h (40 mg/40cm²); *Emsam*® (Bristol-Myers Squibb); (Rx)

SERTRALINE HCL

(sir-trah-leen) Zoloft®

SELECTIVE SEROTONIN REUPTAKE INHIBITOR (SSRI)

Prescriber Highlights

- A selective serotonin reuptake inhibitor that may be useful in treating a variety of behavior-related diagnoses in dogs & cats, including aggression, anxiety-related behaviors & other obsessive-compulsive behaviors
- Caution: geriatric patients or those with severe hepatic disease; dosages may need to be adjusted
- Adverse effect profile not well established. Potentially, DOGS: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Aggressive behavior in previously non-aggressive dogs possible. CATS: Sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), & changes in elimination patterns
- Drug-drug interactions
- Relatively inexpensive generic forms now available

Uses/Indications

Sertraline may be considered for use in treating a variety of behavior-related diagnoses in dogs and cats, including aggression, and anxiety-related or other obsessive-compulsive behaviors.

Pharmacology/Actions

Sertraline is a highly selective inhibitor of the reuptake of serotonin (5-hydroxytryptamine) in the CNS thus potentiating its pharmacologic activity. Sertraline apparently has little effect on dopamine or norepinephrine, and apparently no effect on other neurotransmitters.

Pharmacokinetics

In dogs, sertraline's volume of distribution is 25 L/kg and is 97% bound to plasma proteins. High first-pass metabolism occurs; clearance is greater than 35 mL/min/kg. Bile is the major route of excretion in the dog.

In humans, sertraline peak levels occur 30–45 minutes after oral dosing. It is 98% bound to plasma proteins. Sertraline appears to be highly metabolized primarily to N-desmethylsertraline, which is active. Elimination half-lives for sertraline and desmethylsertraline average 26 and 80 hours respectively.

Contraindications/Precautions/Warnings

Sertraline is contraindicated in patients hypersensitive to it or any SSRI, or receiving a monoamine oxidase inhibitor (MAOI) or cisapride. Use with caution in geriatric patients and those with hepatic impairment; dosages may need to be decreased or dosing interval increased.

Adverse Effects

Limited use of sertraline in dogs or cats makes it difficult to compare its adverse effect profile with other SSRIs (e.g., fluoxetine, paroxetine, fluvoxamine). In dogs, SSRIs can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously non-aggressive dogs has been reported. SSRI's in cats can cause sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), and changes in elimination patterns.

Reproductive/Nursing Safety

In humans, the FDA categorizes sertraline as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In rats and rabbits, sertraline was implicated in causing delayed ossification. Sertraline decreased pup survival in rats exposed in utero.

It is unknown if sertraline enters maternal milk.

Overdosage/Acute Toxicity

In overdoses, the SSRI's can cause vomiting, diarrhea, hypersalivation, and lethargy. Serotonin syndrome may occur with signs that include muscle tremors, rigidity, agitation, hyperthermia, vocalization, hypertension or hypotension, tachycardia, seizures, coma, and death. Human overdoses of as little of 2.5 grams have caused death, but one patient survived after taking 13.5 grams.

There were 469 exposures to sertraline reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 430 were dogs with 38 showing clinical signs and 37 were cats with 4 showing clinical signs. The remaining 2 cases were a bird and an unknown species that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, hyperactivity, tachycardia, agitation and mydriasis. Common findings in cats recorded in decreasing frequency included mydriasis, agitation, anorexia and hallucinating.

Management of sertraline overdoses should be handled aggressively with supportive and symptomatic treatment. Veterinarians are encouraged to contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sertraline and may be of significance in veterinary patients:

- **BUSPIRONE:** Increased risk for serotonin syndrome
- **CIMETIDINE:** May increase sertraline levels
- **CYPROHEPTADINE:** May decrease or reverse the effects of SSRIs
- **DIAZEPAM:** Sertraline may decrease diazepam clearance
- **ISONIAZID:** Increased risk for serotonin syndrome
- **MAO INHIBITORS** (including **amitraz** and potentially, **selegiline**): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing sertraline and a 2 week washout period is required if first discontinuing the MAO inhibitor
- **PENTAZOCINE:** Serotonin syndrome-like adverse effects possible
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., **clomipramine**, **amitriptyline**): Sertraline may increase TCA blood levels and may increase the risk for serotonin syndrome
- **WARFARIN:** Sertraline may increase the risk for bleeding

Laboratory Considerations

No significant laboratory interactions or considerations were located.

Doses

- **DOGS:**
 - a) For treatment of compulsive disorders: 2–4 mg/kg PO once daily or divided twice daily (Landsberg 2004)
 - b) 1–2 mg/kg PO q24h (once daily) (allow 6–8 weeks for initial trial) (Virga 2005b)
 - c) 1–3 mg/kg PO once daily. Plan is to use the drug for a limited time (3–6 months) during which time behavioral modification is also employed. The animal should learn appropriate behavior in previously problematic situations. Then the animal should be weaned off the medication over a 2 to 4 week period by halving the dose weekly (Neilson 2002)
 - d) For treatment of behavioral diagnoses: 0.25–0.5 mg/kg PO q24h (once a day). **Note:** must treat for 3–5 weeks minimum to assess effects; then treat until “well” until either has no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Then treat for another 1–2 months (minimum), so that reliability of assessment is reasonably assured. If weaning off the drug do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)
 - e) For compulsive disorder, anxiety: 1–4 mg/kg PO q24h (once daily) (Seibert 2003)
- **CATS:**
 - a) For treatment of compulsive disorders: 0.5 mg/kg PO once daily (Landsberg 2004)
 - b) For urine marking (spraying), aggression, anxiety—including anxiogenic house soiling, phobias, fears: 0.5–1 mg/kg PO q24h (once daily) (Virga 2002)
 - c) For treatment of behavioral diagnoses: 1 mg/kg PO q24h (once a day). **Note:** must treat for 3–5 weeks minimum to assess effects; then treat until “well” until either has no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Then treat for another 1–2 months (minimum), so that reliability of assessment is reasonably assured. If weaning off the drug do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)

- d) For treatment of fear, affective or dominance aggression: 0.5–1 mg/kg PO once daily (Crowell-Davis 2003b), (Crowell-Davis 2003a)
- e) For treatment of compulsive disorder, anxiety: 0.5–1 mg/kg PO q24h (once daily) (Seibert 2003)

Monitoring

- Efficacy
- Adverse Effects; including appetite (weight)
- Consider doing baseline liver function tests and ECG; re-test as needed

Client Information

- Because there has not as yet been widespread use of sertraline in dogs or cats, its adverse effect and efficacy profiles have not been yet fully determined; clients should report any significant abnormal findings to the veterinarian.
- Clients should understand that this drug is unlikely to have an immediate effect (or even in the short-term) and must commit to using the drug for months to determine efficacy

Chemistry/Synonyms

A selective serotonin reuptake inhibitor, sertraline hydrochloride is a white crystalline powder that is slightly soluble in water and isopropyl alcohol; sparingly soluble in ethanol. The commercially available oral solution contains 12% ethanol and has a menthol scent.

Sertraline may also be known as: CP-51974-01; CP-51974-1; Altruline®, Anilar®, Aremis®, Atenix®, Besitran®, Bicromil®, Gladem®, Insertec®, Irradial®, Lustral®, Novativ®, Sealdin®, Serad®, Sercerin®, Serlain®, Serta®, Tatig®, Tolrest®, Tresleen® or Zoloft®.

Storage/Stability

Store commercially available sertraline tablets and oral solution at controlled room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F). The manufacturer states to dilute the oral solution only in the following liquids: water, orange juice, ginger ale, lemonade or lemon/lime soda; use immediately after dilution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Sertraline HCl Tablets: 25 mg, 50 mg & 100 mg (as base); Zoloft® (Pfizer); generic; (Rx)

Sertraline HCl Oral Concentrate: 20 mg/mL in 60 mL; Zoloft® (Pfizer); (Rx)

SEVELAMER HCL

(se-vel-a-mer) Renagel®

PHOSPHORUS BINDING AGENT

Prescriber Highlights

- Phosphorus binding agent (in the gut) for hyperphosphatemia associated with chronic renal failure
- May be useful if patient cannot tolerate aluminum salts or aluminum salts are commercially unavailable
- Expensive when compared to aluminum hydroxide or calcium carbonate products
- Drug-drug interactions including nutrients

Uses/Indications

Sevelamer may be useful for treating hyperphosphatemia associated with chronic renal failure, particularly when oral aluminum salts are not tolerated.

Pharmacology/Actions

Sevelamer binds phosphorus in the gut; when combined with decreased phosphorus in the diet it can substantially reduce serum phosphorus levels. It also reduces serum low-density lipoproteins and total cholesterol.

Pharmacokinetics

Sevelamer is administered orally, but is not absorbed systemically.

Contraindications/Precautions/Warnings

Sevelamer is contraindicated in patients with hypophosphatemia, or bowel obstruction and in patients hypersensitive to it.

Adverse Effects

Adverse effects in humans are reported to be the same as placebo. Potentially some GI effects occur.

As oral vitamin absorption may be reduced by sevelamer, consider the addition of vitamin supplementation during therapy.

Reproductive/Nursing Safety

Safety during pregnancy is not established; because of the potential for binding vitamins, additional vitamins (both fat and water soluble) may be necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

There are no adequate and well-controlled studies in nursing mothers.

Overdosage/Acute Toxicity

As sevelamer is not absorbed, acute toxicity potential appears to be negligible.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sevelamer and may be of significance in veterinary patients:

- **ANTICONSULSANTS (oral):** Sevelamer may reduce oral absorption; give at least one hour before or three hours after sevelamer capsules

- **ANTIARRHYTHMICS (oral):** Sevelamer may reduce oral absorption; give at least one hour before or three hours after sevelamer capsules
- **CIPROFLOXACIN:** Concurrent administration with sevelamer may decrease absorption by 50%; administer ciprofloxacin and other oral fluoroquinolones at least one hour before or 3 hours after, sevelamer
- **ORAL MEDICATIONS:** There are only a few medications having documented reductions in oral administration when administered with sevelamer; consider dosing other oral drugs separately, particularly for drugs with narrow therapeutic indexes
- **VITAMINS:** Sevelamer may reduce vitamin absorption from food; consider administering vitamin supplements separately from sevelamer dose

Doses

- **DOGS:**
 - a) For medium to large sized dog: 400 mg PO with meals (Vaden 2007)
- **CATS:**
 - a) Has been used at 200 mg 2–3 times daily. Anecdotally appears to be safe and effective. (Sparkes 2006a)

Monitoring

- Serum phosphorus (and other electrolytes calcium, bicarbonate, chloride)
- Consider a baseline coagulation screening test before and after sevelamer therapy implementation as vitamin K absorption may be impacted by the drug

Chemistry/Synonyms

A phosphorus binding agent, sevelamer HCl is a complex chemical that is hydrophilic, but insoluble in water.

Sevelamer may also be known as GT16-026A and *Renagel*®.

Storage/Stability

Sevelamer capsules should be stored at room temperature and protected from moisture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sevelamer HCl Tablets: 400 mg and 800 mg (on an anhydrous basis); *Renagel*® (Genzyme); (Rx)

SEVOFLURANE

(see-voe-floo-rane) SevoFlo®, Ultane®

INHALATIONAL ANESTHETIC

Prescriber Highlights

- ▶ Inhalational anesthetic similar to isoflurane, but with more rapid induction & recovery
- ▶ Currently more expensive than isoflurane

Uses/Indications

Sevoflurane may be useful in a variety of species when rapid induction and/or rapid recoveries are desired with an inhalational anesthetic.

Pharmacology/Actions

While the precise mechanism that inhalant anesthetics exert their general anesthetic effects is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Sevoflurane has a very low blood:gas partition coefficient (0.6) allowing very rapid anesthesia induction and recovery. Rapid mask induction is possible.

Pharmacologic effects of sevoflurane are similar to isoflurane and include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression, hypotension, vasodilatation, myocardial depression (less so than with halothane), and muscular relaxation.

Minimal Alveolar Concentration (MAC; %) in oxygen reported for sevoflurane in various species: Dog = 2.09–2.4; Cat = 2.58; Horse = 2.31; Sheep = 3.3; Swine = 1.97–2.66; Human (adult) = 1.71–2.05. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

Pharmacokinetics

Because of its low solubility in blood, only small concentrations of sevoflurane in the blood are required to be dissolved in blood before alveolar partial pressures are in equilibrium with arterial partial pressures. This low solubility means that sevoflurane is rapidly removed from the lungs. It is unknown what percent sevoflurane is bound to plasma proteins. The majority of sevoflurane is excreted via the lungs, but about 3% is metabolized in the liver via the cytochrome P450 2E1 isoenzyme system.

Contraindications/Precautions/Warnings

Sevoflurane is contraindicated in patients with a history or predilection towards malignant hyperthermia. It should be used with caution (benefits vs. risks) in patients with increased CSF or head injury, or renal insufficiency.

Because of its rapid action, use caution not to overdose during the induction phase. Because of the rapid recovery associated with sevoflurane use caution (and appropriate sedation during the recovery phase), particularly with large animals.

Geriatric animals may require less inhalation anesthetic.

Sevoflurane does not appear to be a good inhalational anesthetic in rabbits (breath holding, struggling).

Adverse Effects

Sevoflurane seems to be well tolerated. Hypotension may occur and is considered dose related. Dose-dependent respiratory depression and GI effects (nausea, vomiting, ileus) have been reported. While cardiodepression generally is minimal at doses causing surgical planes of anesthesia, it may occur; bradycardia is possible.

Malignant hyperthermia may be triggered by this agent (like other inhalational anesthetics).

Sevoflurane can react with carbon dioxide absorbents to produce “compound A”, a nephrotoxin. After extensive clinical use in humans however, nephrotoxicity has not been demonstrated to be of clinical concern.

Sevoflurane should be used in precision, agent-specific, out of circuit vaporizers.

Reproductive/Nursing Safety

No overt fetotoxicity or teratogenicity has been demonstrated in lab animal studies, but definite safety has not been established for use during pregnancy.

Overdosage/Acute Toxicity

In the event of an overdosage, discontinue sevoflurane; maintain airway and support respiratory and cardiac function as necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sevoflurane and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES, LINCOSAMIDES:** May enhance neuromuscular blockade
- **BARBITURATES** (phenobarbital, pentobarbital, etc.): May increase concentrations of inorganic fluoride
- **ISONIAZID:** May increase concentrations of inorganic fluoride
- **MIDAZOLAM:** May potentiate sevoflurane effects; decrease MAC
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS** (atracurium, pancuronium, vecuronium): Additive neuromuscular blockade may occur
- **OPIATES:** May potentiate sevoflurane effects; decrease MAC
- **ST. JOHNS WORT:** Increased risk for anesthetic complications; recommend discontinuing St. John's Wort 5 days in advance of surgery
- **SUCCINYLCHOLINE:** Sevoflurane may enhance effects
- **SYMPATHOMIMETICS** (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.): While sevoflurane sensitizes the myocardium to the effects of sympathomimetics less so than halothane, arrhythmias may still result; caution and monitoring is advised
- **VERAPAMIL:** May cause cardiodepression

Laboratory Considerations

- Inhalational anesthetics may cause transient increases in liver function tests, WBCs, and glucose

Doses

Minimal Alveolar Concentration (MAC; %) in oxygen reported for sevoflurane in various species: Dog = 2.09–2.4; Cat = 2.58; Horse = 2.31; Sheep = 3.3; Swine = 1.97–2.66; Human (adult) = 1.71–2.05. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.)

■ DOGS:

Inspired Concentration: The delivered concentration of *SevoFlo*® (sevoflurane) should be known. Since the depth of anesthesia may be altered easily and rapidly, only vaporizers producing predictable percentage concentrations of sevoflurane should be used. Sevoflurane should be vaporized using a precision vaporizer specifically calibrated for sevoflurane. Sevoflurane contains no stabilizer. Nothing in the drug product alters calibration or operation of these vaporizers. The administration of general anesthesia must be individualized based on the patient's response. **When using sevoflurane, patients should be continuously monitored and facilities for maintenance of patient airway, artificial ventilation, and oxygen supplementation must be immediately available.**

Replacement of Desiccated CO₂ Absorbents: When a clinician suspects that the CO₂ absorbent may be desiccated, it should be replaced. An exothermic reaction occurs when sevoflurane is exposed to CO₂ absorbents. This reaction is increased when the CO₂ absorbent becomes desiccated.

Premedication: No specific premedication is either indicated or contraindicated with sevoflurane. The necessity for and choice of premedication is left to the discretion of the veterinarian. Preanesthetic doses for premedicants may be lower than the label directions for their use as a single medication.

Induction: For mask induction using sevoflurane, inspired concentrations up to 7% sevoflurane with oxygen are employed to induce surgical anesthesia in the healthy dog. These concentrations can be expected to produce surgical anesthesia in 3 to 14 minutes. **Due to the rapid and dose dependent changes in anesthetic depth, care should be taken to prevent overdosing. Respiration must be monitored closely in the dog and supported when necessary with supplemental oxygen and/or assisted ventilation.**

Maintenance: *SevoFlo*® may be used for maintenance anesthesia following mask induction using sevoflurane or following injectable induction agents. The concentration of vapor necessary to maintain anesthesia is much less than that required to induce it. Surgical levels of anesthesia in the healthy dog may be maintained with inhaled concentrations of 3.7–4% sevoflurane in oxygen in the absence of premedication and 3.3–3.6% in the presence of premedication. The use of injectable induction agents without premedication has little effect on the concentrations of sevoflurane required for maintenance. Anesthetic regimens that include opioid, alpha2-agonist benzodiazepine or phenothiazine premedication will allow the use of lower sevoflurane maintenance concentrations. (Label directions; *SevoFlo*®—Abbott Animal Health)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia

Chemistry/Synonyms

Sevoflurane is an isopropyl ether inhalational anesthetic with a molecular wt. of 200, saturate vapor pressure at 20°C of 160 mmHg and a boiling pt. of 58.5°C. It is reported to have a pleasant odor and is not irritating to airways. It is non-flammable and non-explosive. Sevoflurane is a clear, colorless liquid that is miscible with ethanol or ether and slightly soluble in water.

Sevoflurane may also be known as: BAX-3084, MR-654, *Sevocris*®, *SevoFlo*®, *Sevorane*®, or *Ultane*®.

Storage/Stability

Sevoflurane should be stored at room temperature. Sevoflurane does not react with metal.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sevoflurane in 250 mL btl; *SevoFlo*® (Abbott); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

Sevoflurane in 250 mL btl; *Ultane*® (Abbott); (Rx)

SILDENAFIL CITRATE

(sil-den-ah-fil) Viagra®, Revatio®

VASODILATOR; PHOSPHODIESTERASE TYPE 5 INHIBITOR

Prescriber Highlights

- ▶ Used in veterinary medicine for treating pulmonary hypertension
- ▶ Contraindicated if patients receiving organic nitrates
- ▶ Adverse effects not well-known; inguinal flushing, possible GI effects reported
- ▶ Treatment may be very expensive

Uses/Indications

Sildenafil may be of benefit in the adjunctive treatment of pulmonary hypertension in small animals.

In humans, sildenafil is indicated for erectile dysfunction or pulmonary hypertension.

Pharmacology/Actions

Sildenafil inhibits cyclic guanosine monophosphate (cGMP) specific phosphodiesterase type-5 (PDE5) found in the smooth muscle of the pulmonary vasculature, corpus cavernosum and elsewhere, where PDE5 is responsible for degradation of cGMP. Sildenafil increases cGMP thereby resulting in nitric oxide mediated vasodilation within pulmonary vascular smooth muscle cells.

Pharmacokinetics

The pharmacokinetics of sildenafil has been reported in dogs (Walker, Ackland et al. 1999). Oral bioavailability is approximately 50% (higher than humans); volume of distribution is about 5.2 L/kg (versus 1.2 L/kg in humans); elimination half-life approximately 6 hours (significant interpatient variability; average human half life is about 4 hours).

Contraindications/Precautions/Warnings

Sildenafil should not be used concurrently with nitrates (see drug interactions) or in patients documented hypersensitive to it.

Pulmonary vasodilators may significantly worsen the cardiovascular status of patients with pulmonary veno-occlusive disease (PVOD).

Use with extreme caution in patients with resting hypotension, fluid depletion, severe left ventricular outflow obstruction, or autonomic dysfunction.

Adverse Effects

Because of limited use in dogs, the adverse effect profile is not fully known. Cutaneous flushing of the inguinal region has been reported and GI effects are possible. In humans, headache, visual disturbances, dyspepsia, nasal congestion, myalgia, priapism, dizziness, and back pain have been reported.

Reproductive/Nursing Safety

No evidence of teratogenicity, embryotoxicity or fetotoxicity was observed in pregnant rats or rabbits, dosed at 200 mg/kg/day during organogenesis. In a rat pre- and postnatal development study, the no-observed-adverse-effect dose was 30 mg/kg/day. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies*

have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known if sildenafil or its metabolites are excreted in milk.

Overdosage/Acute Toxicity

Little information is available. An adult women ingested 2000 mg and survived but developed tachycardia, nonspecific ST-T changes on ECG, headache, dizziness, and flushing.

It is expected that overdoses in animals would mirror the drugs adverse effect profile; treat supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sildenafil and may be of significance in veterinary patients:

- **ALPHA-ADRENERGIC BLOCKERS** (e.g., phentolamine, phenothiazines, phenoxybenzamine): May increase hypotensive effects
- **AMLODIPINE**: Potential to increase hypotensive effects
- **ANTIHYPERTENSIVE, HYPOTENSIVE DRUGS**: Potentially could increase hypotensive effects
- **AZOLE ANTIFUNGALS** (ketoconazole, itraconazole): May reduce sildenafil metabolism and increase AUC
- **CIMETIDINE**: May reduce sildenafil metabolism and increase AUC
- **ERYTHROMYCIN, CLARITHROMYCIN**: May reduce sildenafil metabolism and increase AUC
- **HEPARIN**: May increase bleeding risks
- **NITRATES** (e.g., NTG, Isosorbide): Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **NITROPRUSSIDE SODIUM**: Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **PHENOBARBITAL**: May decrease sildenafil concentrations
- **RIFAMPIN**: May decrease sildenafil concentrations

Laboratory Considerations

None were noted.

Doses

■ DOGS/CATS:

Dogs: From a retrospective study: median dose was 1.9 mg/kg (range from 0.5–2.7 mg/kg) q8–24h. Dogs may have been also treated with oxygen, ACE inhibitors, furosemide, amlodipine, diltiazem, theophylline, phenobarbital and/or antibiotics. (Bach, Rozanski et al. 2006)

For pulmonary hypertension documented by Doppler, chronic pulmonary disease, right-sided heart failure (HW disease; congenital): 0.5–1 mg/kg PO two times daily (higher dose of 2–3 mg/kg three times a day may be tolerated and needed) (Tilley 2007)

Monitoring

- Clinical efficacy (improved syncope, cough, respiratory effort)
- Pulmonary artery pressure, systemic blood pressure

Client Information

- Brief clients on the experimental nature of using this medication in small animals and the costs of therapy

Chemistry/Synonyms

Sildenafil citrate occurs as a white to off-white crystalline powder with a solubility of 3.5 mg/mL in water and a molecular weight of 666.7.

Sildenafil may also be known as UK 92480, UK 92480-10, *Aphrodisil*®, *Revatio*®, or *Viagra*®.

Storage/Stability

Sildenafil tablets should be stored at room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sildenafil Citrate Tablets: 20 mg (of sildenafil); *Revatio*® (Pfizer); (Rx)

Sildenafil Citrate Tablets: 25 mg, 50 mg & 100 mg (of sildenafil); *Viagra*® (Pfizer); (Rx)

SILYMARIN MILK THISTLE

(sill-e-mar-in) Marin®

NUTRACEUTICAL HEPATO-PROTECTANT

Prescriber Highlights

- ▶ Nutraceutical that may be useful for treatment of chronic & acute liver disease, cirrhosis; as a hepato-protective agent when hepatotoxins (e.g., *Aminita phalloide*) ingested
- ▶ Appears well-tolerated; potentially could cause GI effects
- ▶ Do not confuse Milk Thistle with Blessed Thistle
- ▶ Potential drug interactions

Uses/Indications

While controlled studies demonstrating efficacy and a standardized form and concentration of silymarin are lacking, it is being used to treat a variety of liver diseases in humans and domestic companion animals (birds, dogs, cats, horses, rabbits). It is mostly of interest in treating chronic and acute liver disease, cirrhosis, and as a hepato-protective agent when hepatotoxic agents are ingested (e.g., *Aminita phalloide*; "Death Cap Mushrooms").

Pharmacology/Actions

Silymarin has a variety of pharmacologic actions that may contribute to its apparent effects in treating liver disease. It inhibits lipid peroxidase and beta-glucuronidase and acts as an anti-oxidant and free radical scavenger. Silymarin also inhibits the cytotoxic, inflammatory, and apoptotic effects of tumor necrosis factor (TFN). It apparently can alter outer hepatocyte cell membranes that can prevent toxin penetration. Silymarin is thought to reduce hepatic collagen formation and increase hepatic glutathione content.

Pharmacokinetics

In humans, silymarin has an oral bioavailability of less than 50% and peak levels occur 2–4 hours post-dose. When silibinin (silybin, sylibin) is complexed with phosphatidylcholine, oral absorption can be increased. The drug undergoes extensive enterohepatic circulation and has significantly higher concentrations in liver cells and bile than in plasma. Elimination half-life in humans averages 6 hours. The majority of the drug is eliminated unchanged in the feces, but 20–40% is converted into glucuronide and sulfate conjugates which are eliminated in the feces; only about 8% is excreted in the urine.

Contraindications/Precautions/Warnings

There are no reported absolute contraindications to silymarin in animals. Extracts from the plant parts of Milk Thistle (not the seeds which are used to make the extract silymarin), may possess estrogen-like activity and should not be used in patients where exogenous estrogens would be contraindicated.

Adverse Effects

Silymarin is apparently well tolerated when administered orally. In humans, GI disturbances have been reported on occasion (nausea to diarrhea). Patients who have allergies to other members of the Asteraceae/Compositae plant family (includes ragweed, marigolds, daisies, etc.) may exhibit allergic reactions to Milk Thistle derivatives. Do not confuse Milk Thistle with Blessed Thistle.

Reproductive/Nursing Safety

Data on the safety of silymarin use during pregnancy or nursing is not available; its potential benefit must be weighed against the uncertainty of its safety.

Overdosage/Acute Toxicity

Overdoses are unlikely to cause significant morbidity. Gastrointestinal effects may be seen and treated in a supportive manner.

Drug Interactions

While no specific drug interactions have been reported, silymarin may inhibit cytochrome P450 isoenzyme 2C9 (CYP2C9). Drugs with narrow therapeutic indexes that are metabolized by this isoenzyme should be used with caution when using silymarin. Drugs that could be affected include: **warfarin, amitriptyline, verapamil**, etc.

Silymarin also may inhibit CYP3A4, but thus far this interaction does not appear to be clinically significant. Silymarin may increase the clearance of drugs that undergo hepatic glucuronidation (not cats), including: **acetaminophen, diazepam, morphine, and lamotrigine**. Clinical significance has not been determined for this interaction and the usefulness of silymarin for treating acetaminophen toxicity has not been determined.

Laboratory Considerations

No interactions with laboratory tests are reported.

Doses

■ DOGS & CATS:

- a) Therapeutic dosage is unknown, but suggested doses range from 50–250 mg/day (Twedt 2004)
- b) For adjunctive therapy for chronic liver disease: 20–50 mg/kg per day (extrapolated from human, monkey, rodent and dog research) (Center 2002)
- c) For chronic liver disease and ameliorating the effects of anticonvulsants: Dosages vary from 50–200 mg given every 12–24 hours (Tams 2001)
- d) For hepatotoxicity, hepatic recovery/regeneration, hepatic fibrosis: 20–50 mg/kg/day. (Webb 2007b)
- e) Cats: 4–8 mg/kg/day (Zoran 2006b)

Monitoring

- Clinical efficacy

Client Information

- Because silymarin experience in animals is limited, clients should understand the "investigational nature" of its use

Chemistry/Synonyms

Milk Thistle, the common name for *Silybum marianum*, has been used as a medicinal agent for at least two thousand years. The me-

dicinal extract from the seeds of the plant is silymarin that contains the four flavolignans: silichristin (sylichristin), isosilibinin, silydianin (silidianin), and the most biological active component, silibinin (silybin, silybin, silibide). Milk Thistle extract contains approximately 70% silymarin of which about 70% is silibinin. Silymarin is reportedly fairly insoluble in water.

Silymarin or Milk thistle may also be known as *Carduus marianus*, Holy Thistle, Legalon, or Marian Thistle. Blessed Thistle is a different compound.

Storage/Stability

Unless otherwise labeled, commercially available products containing silymarin should be stored at room temperature in tight containers. Avoid storing the products in areas of high humidity.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Milk Thistle or silymarin is considered a nutritional supplement by the FDA. No standards have been accepted for potency, etc. by regulatory bodies. Supplements are available from a wide variety of sources and dosage forms include tablets and capsules in a variety of concentrations (150–1000 mg). When choosing a product it is recommended to purchase ones that state the concentration (usually 70–80%) of silymarin contained in the product.

Silybin A+B 9 mg (in a phosphatidylcholine complex) & Vitamin E 50 IU Tablets: *Marin® for Cats* (Nutramax); Not considered a drug by the FDA.

Silybin A+B 24 mg (in a phosphatidylcholine complex), Vitamin E 105 IU, & Zinc 17 mg Chewable Tablets: *Marin® for Dogs* (Nutramax); Not considered a drug by the FDA. Labeled for use in small to medium dogs.

Silybin A+B 70 mg (in a phosphatidylcholine complex), Vitamin E 300 IU, & Zinc 45 mg Chewable Tablets: *Marin® for Dogs* (Nutramax); not considered a drug by the FDA. Labeled for use in large dogs.

A combination product (*Denamarin®*, Nutramax) containing SAME and silybin (silymarin) is also labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS: None as pharmaceuticals

SODIUM BICARBONATE

(soe-dee-um bye-kar-boe-nate) Neut®

ALKALINIZER

Prescriber Highlights

- ▶ Alkalinizing agent used to treat metabolic acidosis & alkalinize urine; may be used adjunctively for hypercalcemic or hyperkalemic crises
- ▶ Contraindications: Parenteral bicarbonate is generally contraindicated in patients with metabolic or respiratory alkalosis, excessive chloride loss secondary to vomiting or GI suction, at risk for development of diuretic-induced hypochloremic alkalosis, or with hypocalcemia where alkalosis may induce tetany
- ▶ Extreme Caution: Hypocalcemia Caution: CHF, nephrotic syndrome, hypertension, oliguria or volume overload
- ▶ Adverse Effects: Especially with parenteral (high dose): metabolic alkalosis, hypokalemia, hypocalcemia, “overshoot” alkalosis, hypernatremia, volume overload, congestive heart failure, shifts in the oxygen dissociation curve causing decreased tissue oxygenation, & paradoxical CNS acidosis leading to respiratory arrest. If used during CPR: hypercapnia, if the patient is not well ventilated; patients may be predisposed to ventricular fibrillation.
- ▶ Drug Interactions

Uses/Indications

Sodium bicarbonate is indicated to treat metabolic acidosis and alkalinize the urine. It is also used as adjunctive therapy in treating hypercalcemic or hyperkalemia crises.

Pharmacology/Actions

Bicarbonate ion is the conjugate base component of bicarbonate:carbonic acid buffer, the principal extracellular buffer in the body.

Contraindications/Precautions/Warnings

Parenterally administered sodium bicarbonate is considered generally contraindicated in patients with metabolic or respiratory alkalosis, excessive chloride loss secondary to vomiting or GI suction, at risk for development of diuretic-induced hypochloremic alkalosis, or with hypocalcemia where alkalosis may induce tetany.

Use with extreme caution and give very slowly in patients with hypocalcemia. Because of the potential sodium load, use with caution in patients with CHF, nephrotic syndrome, hypertension, oliguria, or volume overload.

Adverse Effects

Sodium bicarbonate therapy (particularly high-dose parenteral use) can lead to metabolic alkalosis, hypokalemia, hypocalcemia, “overshoot” alkalosis, hypernatremia, volume overload, congestive heart failure, shifts in the oxygen dissociation curve causing decreased tissue oxygenation, and paradoxical CNS acidosis leading to respiratory arrest.

When sodium bicarbonate is used during cardiopulmonary resuscitation, hypercapnia may result if the patient is not well ventilated; patients may be predisposed to ventricular fibrillation.

Oral and parenteral bicarbonate (especially at higher doses) may contribute significant amounts of sodium and result in hyper-

natremia and volume overload; use with caution in patients with CHF, or acute renal failure.

Reproductive/Nursing Safety

Reproductive safety studies have not been performed. Assess risk versus benefit before using.

Overdosage/Acute Toxicity

Sodium bicarbonate can cause severe alkalosis, with irritability or tetany if overdosed or given too rapidly. Dosages should be thoroughly checked and frequent monitoring of electrolyte and acid/base status performed.

Treatment may consist of simply discontinuing bicarbonate if alkalosis is mild or by using a rebreathing mask. Severe alkalosis may require intravenous calcium therapy. Sodium chloride or potassium chloride may be necessary if hypokalemia is present.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sodium bicarbonate and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **AZOLE ANTIFUNGALS (ketoconazole, itraconazole):** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **CIPROFLOXACIN; ENROFLOXACIN:** The solubility of ciprofloxacin and enrofloxacin is decreased in an alkaline environment; patients with alkaline urine should be monitored for signs of crystalluria
- **CORTICOSTEROIDS:** Patients receiving high dosages of sodium bicarbonate and ACTH or glucocorticoids may develop hypernatremia
- **DIURETICS (e.g., thiazides, furosemide):** Concurrent use of sodium bicarbonate in patients receiving potassium-wasting diuretics may cause hypochloremic alkalosis
- **EPHEDRINE:** When urine is alkalinized by sodium bicarbonate, excretion may be decreased
- **HISTAMINE₂ BLOCKING AGENTS (e.g., cimetidine, ranitidine):** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **IRON PRODUCTS:** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **ORAL MEDICATIONS:** Because oral sodium bicarbonate can either increase or reduce the rate and/or extent of absorption of many orally administered drugs, it is recommended to avoid giving other drugs within 1–2 hours of sodium bicarbonate
- **QUINIDINE:** When urine is alkalinized by sodium bicarbonate, excretion may be decreased
- **SALICYLATES:** When urine is alkalinized by sodium bicarbonate, excretion of weakly acidic drugs may be increased
- **SUCRALFATE:** Oral sodium bicarbonate may reduce the efficacy of sucralfate if administered concurrently
- **TETRACYCLINES:** Concomitant oral sodium bicarbonate may reduce absorption; administer separately

Doses

■ DOGS & CATS:

For severe metabolic acidosis:

- a) Main therapeutic goal should be to eliminate the underlying cause of acidosis. If causes are not readily reversible, arterial pH is <7.2 (7.1 if diabetic ketoacidosis), and ventilatory procedures have not reduced acidemia, bicarbonate therapy should be considered. mEq of bicarbonate required = 0.5 x body weight in kgs. x (desired total CO₂ mEq/L minus mea-

sured total CO₂ mEq/L). Give 1/2 of the calculated dose slowly over 3–4 hours IV. Recheck blood gases and assess the clinical status of the patient. Avoid over-alkalinization. (Schaer 1986)

For adjunctive therapy of diabetic ketoacidosis:

Note: Use of bicarb for this indication is somewhat controversial

- a) If plasma bicarbonate is ≤11 mEq/L give bicarbonate therapy. Dose (in mEq) = body weight in kgs. x 0.4 x (12 – patient's bicarbonate) x 0.5. Give above dose over 6 hours in IV fluids and then recheck plasma bicarbonate or total venous CO₂. If still ≤11 mEq/L, recalculate dose and repeat therapy. (Nelson and Feldman 1988)

For metabolic acidosis in acutely critical situations (cardiac arrest):

- a) 1 mEq/kg IV initially, followed by 0.5 mEq/kg at 10–15 minute intervals during CPR (Moses 1988)
- b) Give none during the first 5–10 minutes of arrest, then 0.5 mEq/kg every 5 minutes of cardiac arrest thereafter (Haskins 1989)

For adjunctive treatment of hypercalcemic crisis:

- a) The mEq of bicarbonate required = 0.3 x body weight in kgs. x (desired plasma bicarbonate mEq/L – measured plasma bicarbonate mEq/L); or 1 mEq/kg IV every 10–15 minutes; maximum total dose: 4 mEq/L (Kruger, Osborne, and Polzin 1986)

For adjunctive therapy for hyperkalemic crises:

- a) If serum bicarbonate or total CO₂ is unavailable: 2–3 mEq/kg IV over 30 minutes if patient has decreased tissue perfusion or renal failure and does not have diabetic ketoacidosis. Must be used judiciously. (Willard 1986)
- b) 1–2 mEq/kg IV slowly (Macintire 2006a)

Metabolic acidosis secondary to renal failure:

- a) Dogs: Initial dose: 8–12 mg/kg PO q8h; adjust dosage to attain blood total CO₂ concentrations to 18–24 mEq/L for renal failure. Although, inferior to monitoring total CO₂; urine pH may be used as a guideline for adjusting dosage. Urine pH should be between 6.5–7. (Polzin and Osborne 1985)
- b) Initial dose: 8–12 mg/kg q8h; adjust dosage to attain blood total CO₂ concentrations to 18–24 mEq/L (Allen 1989)
- c) 8–12 mg/kg PO q8–12h (Vaden 2007)

To alkalinize the urine:

- a) Dosage must be individualized to the patient. Initially give 10–90 grains (650 mg–5.85 grams) PO per day, depending on the size of the patient and the pretreatment urine pH value. Goal of therapy is to maintain a urine pH of about 7; avoid pH >7.5. (Osborne et al. 1989)
- b) For adjunctive therapy in dissolution and/or prevention of urate urolithiasis in dogs: 0.5–1 gram (1/8–1/4 tsp.) per 5 kg of body weight three times daily PO. Goal of therapy is to attain a urine pH of from 7–7.5. (Senior 1989)

■ HORSES:

For metabolic acidosis:

- a) Associated with colic; if pH is <7.3 and base deficit is >10 mEq/L estimate bicarbonate requirement using the formula: bicarbonate deficit (HCO³⁻ mEq) = base deficit (mEq/L) x 0.4 x body weight (kg). May administer as a 5% sodium bicarbonate solution. Each L of solution contains 600 mEq of bicarbonate (hypertonic) and should not be administered any faster than 1–2 L/hr. Because acidotic horses with colic tend also to be dehydrated, may be preferable to give as isotonic sodium bicarbonate (150 mEq/L). (Stover 1987)

■ RUMINANTS:

For acidosis:

- 2–5 mEq/kg IV for a 4–8 hour period (Howard 1986)
- For severely dehydrated (10–16% dehydrated) acidotic calves (usually comatose): Use isotonic sodium bicarbonate (156 mEq/L). Most calves require about 2 liters of this solution given over 1–2 hours, then change to isotonic saline and sodium bicarbonate or a balanced electrolyte solution. Isotonic sodium bicarbonate may be made by dissolving 13 grams of sodium bicarbonate in 1 L of sterile water. Isotonic saline and sodium bicarbonate may be made by: mixing 1 L of isotonic saline with 1 L of isotonic sodium bicarbonate. (Radostits 1986)

■ BIRDS:

For metabolic acidosis:

- 1 mEq/kg initially IV (then SC) for 15–30 minutes to a maximum of 4 mEq/kg (Clubb 1986)

Monitoring

- Acid/base status
- Serum electrolytes
- Urine pH (if being used to alkalinize urine)

Chemistry/Synonyms

An alkalinizing agent, sodium bicarbonate occurs as a white, crystalline powder having a slightly saline or alkaline taste. It is soluble in water and insoluble in alcohol. One gram of sodium bicarbonate contains about 12 mEq each of sodium and bicarbonate; 84 mg of sodium bicarbonate contains 1 mEq each of sodium and bicarbonate. A 1.5% solution of sodium bicarbonate is approximately isotonic. An 8.4% solution of sodium bicarbonate can be made isotonic by diluting each mL with 4.6 mL of sterile water for injection.

Sodium Bicarbonate may also be known as: baking soda, E500, monosodium carbonate, natrii bicarbonas, natrii hydrogenocarbonas, sal de vichy, sodium acid carbonate, NaHCO_3 , sodium hydrogen carbonate; many trade names are available.

Storage/Stability/Compatibility

Sodium bicarbonate tablets should be stored in tight containers, preferably at room temperature (15–30°C). Sodium bicarbonate injection should be stored at temperatures less than 40°C and preferably at room temperature; avoid freezing.

Sodium bicarbonate powder is stable in dry air, but will slowly decompose upon exposure to moist air.

Sodium bicarbonate is reportedly physically **compatible** with the following intravenous solutions and drugs: Dextrose in water, dextrose/saline combinations, dextrose-Ringer's combinations, sodium chloride injections, amikacin sulfate, aminophylline, amobarbital sodium, amphotericin B, atropine sulfate, bretylium tosylate, carbenicillin disodium, cefoxitin sodium, cephalothin sodium, cephapirin sodium, chloramphenicol sodium succinate, chlorothiazide sodium, cimetidine HCl, clindamycin phosphate, ergonovine maleate, erythromycin gluceptate/lactobionate, *Innovar*®, heparin sodium, hyaluronidase, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, metaraminol bitartrate, methotrexate sodium, methyl Dopate HCl, nafcillin sodium, netilmicin sulfate, oxacillin sodium, oxytocin, phenobarbital sodium, phenylephrine HCl, phenytoin sodium, phytonadione, potassium chloride, prochlorperazine edisylate, and sodium iodide.

Sodium bicarbonate **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: lactated Ringer's injection, Ringer's injection, sodium lactate 1/6 M, ampicillin sodium, calcium chloride/gluconate, methicillin sodium, penicillin G potassium, pentobarbital sodium,

promazine HCl, thiopental sodium, vancomycin HCl, verapamil HCl, and vitamin B-complex with C. Consult specialized references or a hospital pharmacist for more specific information.

Sodium bicarbonate is reportedly physically **incompatible** with the following solutions or drugs: alcohol 5%/dextrose 5%, D5 lactated Ringer's, amrinone lactate, ascorbic acid injection, carmustine, cisplatin, codeine phosphate, corticotropin, dobutamine HCl, epinephrine HCl, glycopyrrolate, hydromorphone HCl, imipenem-cilastatin, regular insulin, isoproterenol HCl, labetalol HCl, levorphanol bitartrate, magnesium sulfate, meperidine HCl, methadone HCl, metoclopramide HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, procaine HCl, secobarbital sodium, streptomycin sulfate, succinylcholine chloride, tetracycline HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 50 mL (50 mEq/vial), 100 mL (100 mEq/vial) and 500 mL (500 mEq/vial) vials; available generically labeled; (Rx)

HUMAN-LABELED PRODUCTS:

Injectable Products:

Sodium Bicarbonate Neutralizing Additive Solution: 4% (0.48 mEq/mL) in 5 mL (2.4 mEq) vials; 4.2% (0.5 mEq/mL) in 5 mL fill in 6 mL vials (2.5 mEq); *Neut*® (Abbott); Sodium Bicarbonate (American Pharmaceutical Partners); (Rx)

Sodium Bicarbonate Injection: 4.2% (0.5 mEq/mL) in 10 mL (5 mEq) syringes, 10 mL (5 mEq) *Bristoject* syringes; generic, (Hospira, American Pharmaceutical Partners); (Rx)

Sodium Bicarbonate Injection: 5% (0.6 mEq/mL) in 500 mL vials (297.5 mEq); generic, (Hospira, Baxter, McGaw); (Rx)

Sodium Bicarbonate Injection: 7.5% (0.9 mEq/mL) in 50 mL (44.6 mEq) amps, syringes, vials, *Bristoject* syringes and 200 mL (179 mEq) *MaxiVials*; generic (Hospira, American Regent, American Pharmaceutical Partners); (Rx)

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 10 mL (10 mEq) and 50 mL (50 mEq) syringes and 50 mL vials (50 mEq/vial); generic (Hospira, American Regent, American Pharmaceutical Partners); (Rx)

Oral Products:

Tablets: 325 mg & 650 mg; (1 g sodium bicarbonate provides 11.9 mEq sodium and 11.9 mEq bicarbonate); generic; (OTC)

Powder: 120 g, 300 g & 1 lb; generic; (OTC)

Omeprazole/Sodium Bicarbonate Capsules (immediate release): 20 mg omeprazole/1,100 mg sodium bicarbonate & 40 mg omeprazole/1,100 mg sodium bicarbonate; *Zegerid*® (Santarus); (Rx)

Omeprazole/Sodium Bicarbonate Powder for Oral Suspension: 20 mg omeprazole/1,680 mg sodium bicarbonate & 40 mg omeprazole/1,680 mg sodium bicarbonate; *Zegerid*® (Santarus); (Rx)

SODIUM POLYSTYRENE SULFONATE

(soe-dee-um pol-ee-stye-reen *sulf-foe-nate*)

Kayexalate®, SPS

CATIONIC EXCHANGE RESIN (HYPERKALEMIA)

Prescriber Highlights

- ▶ Cation exchange resin used to treat hyperkalemia
- ▶ Contraindications: Patients who cannot tolerate a large sodium load
- ▶ Cause of hyperkalemia must be addressed
- ▶ Adverse Effects: Constipation, anorexia, vomiting, or nausea. Overdosage/overuse may lead to hypokalemia, hypocalcemia & hypomagnesemia.
- ▶ If given PO, often mixed with sorbitol to expedite removal of resin (& potassium)
- ▶ Drug Interactions

Uses/Indications

SPS is indicated as adjunctive treatment of hyperkalemia. The cause of the hyperkalemia should be elucidated and corrected if possible.

Pharmacology/Actions

SPS is a resin that exchanges sodium for other cations. After being given orally, hydrogen ions will be exchanged for sodium (in an acidic environment). As the resin travels through the intestinal tract, the hydrogen ions will be exchanged with other more concentrated cations. Primary exchange with potassium occurs predominantly in the large intestine. When given as a retention enema, SPS generally exchanges sodium for potassium directly in the colorectum. While theoretically, up to 3.1 mEq of potassium could be exchanged per gram of SPS, it is unlikely that more than one mEq will be exchanged per gram of resin administered.

Pharmacokinetics

SPS is not absorbed from the GI tract. Its onset of action may be from hours to days; so severe hyperkalemia may require other treatments (e.g., dialysis) in the interim.

Contraindications/Precautions/Warnings

Because large quantities of sodium may be released and absorbed, patients on severely restricted sodium diets (severe CHF, hypertension, oliguria) may benefit from alternative methods of treatment. Overdosage/overuse may lead to hypokalemia, hypocalcemia and hypomagnesemia.

Adverse Effects

Large doses may cause constipation (fecal impactions have been reported rarely), anorexia, vomiting or nausea. Dose related hypocalcemia, hypokalemia and sodium retention have also been noted. To hasten the drug's action and prevent constipation, SPS is generally mixed with 70% sorbitol (3–4 mL per one gram of resin) when dosed orally.

Reproductive/Nursing Safety

While reproductive studies have apparently not been performed, it is unlikely the drug carries much teratogenic potential. In humans, the FDA categorizes this drug as category C for use during

pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

As SPS is not absorbed, it should be safe to use during nursing.

Overdosage/Acute Toxicity

Overdosage may cause the adverse effects noted (above); treat symptomatically.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving SPS and may be of significance in veterinary patients:

- **ANTACIDS, LAXATIVES (calcium- or magnesium-containing):** SPS may bind with magnesium or calcium found in laxatives (milk of magnesia, magnesium sulfate, etc.) or antacids which can prevent bicarbonate ion neutralization and lead to metabolic alkalosis. Concurrent use is not recommended during SPS therapy.

Doses

If dosed orally, to hasten the drug's action and to prevent constipation SPS is generally mixed with 70% sorbitol (3–4 mL per one gram of resin); shake well before using.

■ DOGS:

- a) For hyperkalemia: 2 grams of resin/kg of body weight (each gram should be suspended in 3–4 mL of water; or use commercially prepared suspension products) divided into 3 daily doses. If given orally, give with a cathartic. Do not use a cathartic if using as a retention enema as it must be in the colon for at least 30 minutes. To prepare a retention enema from the powder: add 15 grams per 100 mL of a 1% methylcellulose solution or 10% dextrose. If hyperkalemia is severe: 3–4 times the normal amount of resin may be given. (Willard 1986)
- b) For mild hyperkalemia (<6 mEq/L): 2 grams/kg PO in 3–4 divided doses with 20% sorbitol; may also be given as an enema without sorbitol. (Cowgill and Francey 2005)

■ HORSES:

- a) For life-threatening hyperkalemia in neonatal foals: 15 grams of resin in 100 mL of 10% dextrose via enema. Monitor serum potassium and sodium closely. (Madigan 2002b)

Monitoring

- Serum electrolytes (sodium potassium (at least once a day), calcium, magnesium)
- Acid/base status, ECG, if warranted

Chemistry/Synonyms

A sulfonated cation exchange resin, sodium polystyrene sulfonate (SPS) occurs as a golden brown, fine powder. It is odorless and tasteless. Each gram contains 4.1 mEq of sodium and has an *in vitro* exchange capacity of about 3.1 mEq of potassium (in actuality a maximum of 1 mEq is usually exchanged).

Sodium Polystyrene Sulfonate may also be known as: natrii polystyrenesulfonas, sodium polystyrene sulphonate, *Elutit-Natrium*®, *K-Exit*®, *Kayexalate*®, *Kexelate*®, *Kionex*®, *Resinsodio*®, *Resonium*®, *Resonium A*®, or SPS®.

Storage/Stability

Store products in well-closed containers at room temperature; do not heat. Suspensions made from powder should be freshly prepared and used within 24 hours.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Sodium Polystyrene Sulfonate Powder: Sodium content is approximately 100 mg (4.1 mEq) per g; in 1 lb. jars & 454 g; *Kayexalate*® (Sanofi Winthrop); *Kionex*® (Paddock); (Rx)

Sodium Polystyrene Sulfonate Suspension: 15 g/60 mL (sodium 1.5 g, 65 mEq) in 60 mL, 120 mL, 200 mL, 480 mL, 500 mL and UD 60 mL; *SPS*® (Carolina Medical Products Co); generic; (Roxane); (Rx)

SODIUM STIBOGLUCONATE SODIUM ANTIMONY GLUCONATE

(sti-boe-gloo-koe-nate; an-ti-moe-nee gloo-koe-nate)

Pentostam®

ANTILEISHMANIAL

Prescriber Highlights

- ▶ Antimony compound for treatment of leishmaniasis in humans & dogs
- ▶ Not commercially available in USA (CDC distributes)
- ▶ Contraindicated in renal failure, pre-existing arrhythmias
- ▶ Many potential adverse effects, including some very serious

Uses/Indications

Sodium stibogluconate is used for the treatment of leishmaniasis in dogs.

Pharmacology/Actions

Sodium stibogluconate's exact mode of action is unknown. It is believed that it may reduce ATP and GTP synthesis in susceptible amastigotes.

Pharmacokinetics

In dogs, stibogluconate's volume of distribution (steady-state) was 0.25 L/kg, clearance 1.71 L/kg/hr, and terminal half-life ranged from 0.6–1.5 hours. The main route of excretion is via the kidneys; glomerular filtration rate determines excretion rate.

Contraindications/Precautions/Warnings

Stibogluconate is contraindicated in patients with pre-existing cardiac arrhythmias, or significantly impaired renal function. It should not be used in those that have had a serious adverse reaction to a previous dose.

Adverse Effects

Dogs given 40 mg/kg of stibogluconate developed increased AST levels. Other reported adverse effects (incidence unknown) include pain on injection, musculoskeletal pain, hemolytic anemia, leukopenia, vomiting, diarrhea, pancreatitis, myocardial injury and arrhythmias, renal toxicity, shock and sudden death. Intravenous administration can cause thrombophlebitis. Reportedly, the incidence of adverse effects increases if the drug is administered for longer than 2 months.

Reproductive/Nursing Safety

Sodium stibogluconate has not been shown to cause fetal harm, but the manufacturer states that the drug should be withheld during pregnancy unless the benefits outweigh the risks.

The use of this drug during nursing is controversial. Some (e.g., The American Academy of Pediatrics) say that it is usually compatible with breast-feeding, but the manufacturer states that it should not be used in nursing mothers.

Overdosage/Acute Toxicity

In the unlikely event of a parenterally administered overdose, it is suggested to contact an animal poison control center. Potentially, antimony can be chelated with dimercaptosuccinic acid (DMSA) or d-penicillamine.

Drug Interactions

No specific drug interactions were noted. Stibogluconate has reportedly been used with allopurinol, paromomycin, or pentamidine without problems.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses**■ DOGS:**

- For treatment of cutaneous leishmaniasis: 30–50 mg/kg IV or SC daily for 3–4 weeks (Anon 2004), (Brosey 2005)

Monitoring

- Laboratory and clinical signs associated with adverse effects (CBC, liver enzymes, renal function tests, ECG, etc.)
- Bone marrow cultures for Leishmania
- Clinical efficacy

Client Information

- Clients should understand the potential public health implications of this disease (dependent on country) in dogs, the guarded prognosis (even with treatment), risks of treatment and associated expenses.

Chemistry/Synonyms

Sodium stibogluconate is a pentavalent antimony compound that contains between 30–34% antimony and is a colorless, odorless or almost odorless, amorphous powder. Sodium stibogluconate is very soluble in water and practically insoluble in alcohol or ether. The commercially available (not in the USA) injection has a pH between 5–5.6.

Sodium stibogluconate may also be known as: sodium antimony gluconate, *stiboglucate-natrium*, *natriumstibogluconat-9-wasser*, *solusurmin*, *stibogluconat*, *sodio stibogluconato*, and *natrii stibogluconas*.

Storage/Stability

The commercially available injection (*Pentostam*®) should be stored at temperatures below 25°C (76°F) and protected from freezing and exposure to light. After removing the first dose, the vial should not be used after one month.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:** None in the USA.

Sodium Stibogluconate (sodium antimony gluconate) 100 mg (of antimony)/mL for injection in 6 mL and 100 mL (*Pentostam*®—Wellcome Foundation) is available from the Centers for Disease Control (CDC). It may or may not be released for use in domestic ani-

mals. Contact the CDC at 404-639-3670 from 8 AM-4:30 PM Eastern Time, Monday-Friday for more information or go to their website: www.cdc.gov/ncidod/srp/drugs/drug-service.html

Pentostam® is available commercially in several countries.

SODIUM SULFATE GLAUBER'S SALT

(soe-dee-um sul-fayte; glow-ber's salt)

SALINE CATHARTIC

Prescriber Highlights

- Used primarily in food animals
- Contraindications: Dehydration
- Caution in patients with severe CHF or in patients otherwise susceptible to sodium retention
- Adverse Effects: Diarrhea, cramping, & flatulence may result; electrolyte abnormalities may occur with chronic use

Uses/Indications

Sodium sulfate is used as a saline cathartic, primarily in food animals.

Pharmacology/Actions

When given orally, sodium sulfate acts as a saline cathartic (draws water into small intestine). Sodium sulfate is considered the most effective saline cathartic on a molar basis. Sulfates also react with a variety of cations to form non-absorbable compounds, which may explain their efficacy in reducing copper loads and reduce gut calcium.

Pharmacokinetics

Sodium sulfate is not appreciably absorbed from the GI tract and thereby acts a saline cathartic. Sodium may be absorbed however, after exchanging with other cations.

Contraindications/Precautions/Warnings

Saline cathartics should not be used in dehydrated animals. Because of the drug's high sodium content, it should be used with caution in patients with severe CHF or otherwise susceptible to sodium retention.

Adverse Effects

Diarrhea, cramping, and flatulence may result. Electrolyte abnormalities may occur with chronic use.

Drug Interactions/Laboratory Considerations

No specific drug or laboratory interactions or considerations were noted.

Doses

Note: When used in food animals, FARAD states that this salt is rapidly excreted and is not considered a residue concern in animal tissues; therefore, a 24 hour preslaughter withdrawal interval (WDI) would be sufficient. (Haskell, Payne et al. 2005)

■ CATTLE:

- a) As a cathartic: 500–750 g PO as a 6% solution via stomach tube (Davis 1993)

■ SHEEP & GOATS:

- a) As a cathartic: 60 g PO as a 6% solution via stomach tube (Davis 1993)

■ SWINE:

- a) As a cathartic: 30–60 g PO as a 6% solution via stomach tube (Davis 1993)

Chemistry/Synonyms

Sodium sulfate (hexahydrate form) occurs as large, colorless, odorless, crystals or white crystalline powder. It will effloresce in dry air and partially dissolve in its own water of crystallization at about 33°C. 1 gram is soluble in about 2.5 mL of water.

Sodium sulfate may also be known as E514, Glauber's Salt, natrii sulphas, natrio sulfata, or natrium sulfuricum.

Storage/Stability

Store in tight containers at temperatures not exceeding 30°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Sodium sulfate (hexahydrate) is available from chemical supply houses.

SODIUM THIOSULFATE

(soe-dee-um thye-oh-sul-fayte) Sodium Hyposulfite

ANTIDOTE (ARSENIC, CYANIDE)

Prescriber Highlights

- Used for cyanide or arsenic poisoning
- Contraindications: None
- Adverse Effects: Large doses by mouth may cause profuse diarrhea
- Injectable forms should be given slowly IV

Uses/Indications

Sodium thiosulfate (alone or in combination with sodium nitrite) is useful in the treatment of cyanide toxicity. It has been touted for use in treating arsenic or other heavy metal poisonings, but its efficacy is in question for these purposes. However, because sodium thiosulfate is relatively non-toxic and inexpensive, it may be tried to treat arsenic poisoning. When used in combination with sodium molybdate, sodium thiosulfate may be useful for the treatment of copper poisoning.

Sodium thiosulfate may be useful for the topical treatment for some fungal infections (Tinea). In humans, sodium thiosulfate has been used to reduce the nephrotoxicity of cisplatin therapy. A 3 or 4% solution has been used to infiltrate the site of extravasations of cisplatin, carboplatin, or dactinomycin. In combination with steroids, sodium thiosulfate may reduce the healing time associated with doxorubicin extravasation.

Pharmacology/Actions

By administering thiosulfate, an exogenous source of sulfur is available to the body, thereby hastening the detoxification of cyanide using the enzyme rhodanese. Rhodanese (*thiosulfate cyanide sulfurtransferase*) converts cyanide to the relatively nontoxic thiocyanate ion; thiocyanate is then excreted in the urine.

Sodium thiosulfate has been used in humans to treat extravasation injuries secondary to carboplatin or cisplatin, for prophylaxis to prevent nephrotoxicity after cisplatin overdoses and ototoxicity with carboplatin overdoses.

Sodium thiosulfate's topical antifungal activity is probably due to its slow release of colloidal sulfur.

While sodium thiosulfate has been recommended for treating arsenic (and some other heavy metal) poisoning, the proposed mechanism of action is not known and its efficacy is in question. Presumably, the sulfate moiety may react with and chelate the metal allowing its removal.

Pharmacokinetics

Sodium thiosulfate is relatively poorly absorbed from the GI tract. When substantial doses are given PO, it acts a saline cathartic. When administered intravenously, it is distributed in the extracellular fluid and then rapidly excreted via the urine.

Contraindications/Precautions/Warnings

There are no absolute contraindications to the use of the drug.

Adverse Effects

The drug is relatively non-toxic. Large doses by mouth may cause profuse diarrhea. Injectable forms should be given slowly IV.

Reproductive/Nursing Safety

Safe use during pregnancy has not been established; use when benefits outweigh the potential risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

No lactation information was found.

Drug Interactions/Laboratory Considerations

No specific drug or laboratory interactions or considerations were noted.

Doses

■ DOGS, CATS:

- For cyanide toxicity: Contact an animal poison control center for guidance.
- For treating extravasation injuries secondary to doxorubicin, carboplatin, cisplatin infusions: **Note:** These are recommendations for human patients.

Doxorubicin: Subcutaneous sodium thiosulfate 2% added to therapy with subcutaneous hydrocortisone and topical betamethasone decreased the healing time by half for cytotoxic drug extravasation (including doxorubicin and epirubicin) when compared to therapy without sodium thiosulfate.

Carboplatin: Prepare a 0.17 moles/L solution by mixing 4 mL sodium thiosulfate 10% w/v with 6 mL sterile water for injection. Inject 5 mL into extravasation site.

Cisplatin: For extravasation of large amounts (greater than 20 mL) of highly concentrated (greater than 0.5 mg/mL) solutions: Prepare a 0.17 moles/L solution by mixing 4 mL sodium thiosulfate 10% w/v with 6 mL sterile water for injection. Inject into extravasation site. (DRUGDEX® Evaluations. Micromedex Healthcare Series; Thompson, 2007)

■ HORSES:

- For cyanide toxicity: First give sodium nitrite at a dose of 16 mg/kg IV followed with a 20% solution of sodium thiosulfate given at a dose of 30–40 mg/kg IV. If repeating treatment, use sodium thiosulfate only. (Bailey and Garland 1992)

- For cyanide toxicity: First give sodium nitrite in a 20% solution at a dose of 10–20 mg/kg IV followed with a 20% solution of sodium thiosulfate given at a dose of 30–40 mg/kg IV (Osweiler 2003)
- For arsenic toxicity: Sodium thiosulfate at 20–30 grams in 300 mL of water orally with dimercaprol (BAL) 3 mg/kg IM q4h (Jones 2004c)

■ RUMINANTS:

Note: When used in food animals, FARAD states that this salt is rapidly excreted and is not considered a residue concern in animal tissues; therefore, a 24 hour preslaughter withdrawal interval (WDI) would be sufficient. (Haskell, Payne et al. 2005)

- In combination with sodium molybdate for the treatment of copper poisoning: In conjunction with fluid replacement therapy, 500 mg sodium thiosulfate in combination with 200 mg ammonium or sodium molybdate PO daily for up to 3 weeks will help decrease total body burden of copper (Thompson and Buck 1993)
- For treatment of cyanide toxicity secondary to cyanogenic plants: 660 mg/kg IV sodium thiosulfate in a 30% solution given rapidly using a 12 or 14 gauge needle (Nicholson 1993), (Post and Keller 2000)
- For treatment of arsenic poisoning: 30–60 grams PO every 6 hours for 3–4 days and 30–60 grams as a 10–20% solution IV may be potentially useful in binding arsenic. Adjunctive fluid and electrolyte replacement is necessary. (Galey 1993)

Chemistry/Synonyms

Sodium thiosulfate occurs as large, colorless crystals or coarse, crystalline powder. It is very soluble in water, deliquescent in moist air and effloresces in dry air at temperatures >33°C.

Sodium thiosulfate may also be known as: natrii thiosulfas, natrium thiosulfuricum, sodium hyposulphite, sodium thiosulphate, *Consept Step 2®*, *Hiposul®*, *Hyposulfene®*, or *S-hydril®*.

Storage/Stability/Compatibility

Unless otherwise stated by the manufacturer, store at room temperature. Crystals should be stored in tight containers.

Sodium thiosulfate is **not compatible** mixed with cyanocobalamin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sodium Thiosulfate for Injection: 10% (100 mg/mL, as pentahydrate) & 25% (250 mg/mL) preservative-free in 10 mL & 50 mL single-use vials; generic, (American Regent); (Rx)

SOMATOTROPIN (GROWTH HORMONE)

(soe-ma-toe-troe-pin)

HORMONE

Prescriber Highlights

- Used for canine hypopituitary dwarfism or growth hormone-responsive dermatosis (in adult dogs).
- May cause diabetes mellitus
- Availability & expense issues

Uses/Indications

Somatotropin may be useful in treating hypopituitary dwarfism or growth hormone-responsive dermatosis (in adult dogs).

Pharmacology/Actions

Growth hormone (somatotropin) is responsible for, or contributes to, linear and skeletal growth, organ growth, and cell growth. It also is a factor in protein, carbohydrate, lipid, connective tissue, and mineral metabolism.

Pharmacokinetics

No canine information was located. Both the liver and kidney are major elimination organs for somatotropin.

Contraindications/Precautions/Warnings

Growth hormone derived from other species is contraindicated in patients hypersensitive to it.

Adverse Effects

Growth hormone may cause diabetes mellitus in dogs. This may be transient or permanent even after discontinuing treatment. Blood and urine glucose should be routinely monitored. If blood glucose exceeds 150 mg/dl, therapy should be stopped. Hypersensitivity reactions are possible, but less so if using porcine origin product. Long-term treatment at high doses may cause acromegaly. Acromegaly in dogs can cause increased size of paws and head, increased skin folds around head and neck area, prognathism, and inspiratory stridor.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

Acute overdosage could cause hypoglycemia initially and then hyperglycemia. Blood glucose should be monitored and supportive treatment (glucose/insulin) performed.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving somatotropin and may be of significance in veterinary patients:

- **GLUCOCORTICOIDs:** May inhibit the growth promoting effect of somatotropin. When concurrent adrenal insufficiency is diagnosed, adjust glucocorticoid dose carefully to avoid negative effects on growth.

Doses

■ DOGS:

- a) For treatment of hypopituitary dwarfism: 0.1 IU (0.05 mg)/kg SC three times per week for 4–6 weeks. **Note:** May also require life-long thyroid hormone supplementation and if secondary adrenal insufficiency present, glucocorticoid treatment. If after successful treatment, dermatologic signs recur, may dose as above (0.1 IU/kg three times weekly for one week). Repeat these weekly regimens at intervals determined by the time lapse between treatments and relapse. (Feldman and Nelson 1996)
- b) For treatment of growth hormone-responsive dermatosis in adult dogs: Dose as above (a), but thyroid and steroid supplementation not required (Feldman and Nelson 1996)
- c) For Alopecia X: 0.15 IU/kg of porcine growth hormone SC 2 times weekly for 6 weeks. (Hillier 2006a)

Monitoring

- Clinical efficacy
- Blood glucose (weekly)
- Urine glucose (daily)
- Thyroid function, adrenal function initially and then periodically (pituitary dwarfism pts.)

Client Information

- Clients should be instructed on the methods for SC injection and testing urine glucose
- May be expensive to treat and diabetes (permanent) can occur

Synonyms

Somatotropin may also be known as: CB-311, HGH, human growth hormone, LY-137998, somatotropin; many trade names are available.

Dosage Forms/Regulatory Status

There are several manufacturers of human recombinant DNA origin somatotropin products, but these are expensive, can cause immunogenicity reactions in dogs, and not sold for veterinary use.

The bovine recombinant growth hormone product (*Posilac*®—Monsanto) is not suitable for canine use as it is a sustained release formulation and not easily diluted down to the smaller doses required for dogs.

Porcine growth hormone appears to have little immunogenicity in dogs and reportedly can be obtained via: Dr A. F. Partlow at: 310-222-3537 E-Mail: Partlow@HUMC.edu WEBSITE: www.humc.edu/hormones

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

SOTALOL HCL

(*soh-ta-lole*) Betapace®

BETA-ADRENERGIC BLOCKER

Prescriber Highlights

- ▶ Non-selective beta blocker/Class III antiarrhythmic for ventricular tachycardia
- ▶ Adverse Effects: Most serious: negative inotropism & pro-arrhythmic but dyspnea/bronchospasm, fatigue/dizziness, & nausea/vomiting possible
- ▶ Treatment is relatively expensive

Uses/Indications

Sotalol may be useful in the treatment of ventricular tachycardias and, possibly, supraventricular tachycardias in dogs.

Pharmacology/Actions

Sotalol is a non-selective beta-blocker and Class III antiarrhythmic agent. The beta blocking activity of sotalol is about 30% that of propranolol. Its primary usage in veterinary medicine is associated with its antiarrhythmic activity. Like other Class III drugs, it prolongs repolarization and refractoriness without affecting conduction. The pharmacologic action is believed caused by selectively inhibiting potassium channels.

Pharmacokinetics

Unlike propranolol, sotalol does not have any appreciable first pass effect after oral administration. Food may reduce the bioavailability of sotalol by approximately 20% (human data) and, if given on an empty stomach, bioavailability is 90–100%. The drug has relatively low lipid solubility and virtually no protein binding. Elimination is almost all via the kidney and most of the drug is excreted unchanged. In dogs, sotalol's elimination half-life is 5 hours; in humans about 12 hours.

Contraindications/Precautions/Warnings

Sotalol is considered contraindicated in patients with asthma, sinus bradycardia, 2nd or 3rd degree heart block (unless artificially paced), long Q-T syndromes, cardiogenic shock or uncontrolled CHF. Because of the potential for negative inotropic effects, use with caution in CHF. Also, use with caution in patients with diabetes mellitus, or hyperthyroidism (may mask signs). Use with caution in patients with renal dysfunction; dosage intervals may need to be extended.

Adverse Effects

Primary concerns with sotalol in dogs are the potential for negative inotropic and proarrhythmic effects. These generally are not clinically important if dosage is not excessive. Other potential adverse effects include dyspnea/bronchospasm, fatigue/dizziness, and nausea/vomiting.

Reproductive/Nursing Safety

Sotalol did not cause any fetotoxicity or teratogenicity when given to pregnant lab animals at high dosages, but clear safety in pregnancy has not been established. Sotalol enters maternal milk in concentrations up to 5X found in the serum; consider using milk replacer in nursing animals.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Sotalol is excreted in milk; use with caution in nursing patients. It is not recommended for use in nursing humans.

Overdosage/Acute Toxicity

Overdoses may result in bradycardia, hypotension, CHF, bronchospasm, and hypoglycemia. Use gut evacuation (if not contraindicated) when significant risk of morbidity is possible. Treat adverse effects symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sotalol and may be of significance in veterinary patients:

- **AMIODARONE:** May prolong refractory periods; concurrent use not recommended in human patients
- **ANESTHETICS, GENERAL:** Additive myocardial depression may occur with the concurrent use of sotalol and myocardial depressant anesthetic agents
- **ANTACIDS:** May reduce oral sotalol absorption; separate doses by at least 2 hours
- **ANTIARRHYTHMICS, CLASS IA (quinidine, procainamide, disopyramide):** May prolong refractory periods; concurrent use not recommended in human patients; may also prolong QT interval

- **ANTIARRHYTHMICS, CLASS IB, 1C (lidocaine, mexiletine, phenytoin, flecainide etc.):** May prolong QT interval
- **CALCIUM CHANNEL BLOCKERS (verapamil, diltiazem, etc.):** Potential to increase hypotensive effects; may have additive effects on AV conduction or ventricular function; use with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **CISAPRIDE:** May prolong QT interval
- **CLONIDINE:** If clonidine is discontinued after concomitant therapy with sotalol, there is an increased risk for rebound hypertension
- **DIGOXIN:** Potential for increased risks for proarrhythmic events
- **ERYTHROMYCIN; CLARITHROMYCIN:** May prolong QT interval
- **LIDOCAINE:** Clearance may be impaired by sotalol
- **PHENOTHIAZINES:** May prolong QT interval
- **RESERPINE:** May have additive effects (hypotension, bradycardia) with sotalol
- **SYMPATHOMIMETICS, BETA 2 AGONISTS (e.g., metaproterenol, terbutaline, albuterol):** May have their actions blocked by sotalol
- **TRICYCLIC ANTIDEPRESSANTS:** May prolong QT interval

Laboratory Considerations

- Beta-blockers may produce hypoglycemia and interfere with glucose or insulin tolerance tests
- Sotalol may falsely elevate urine metanephrine levels (pheochromocytoma screen) if using a fluorometric or photometric assay

Doses

- **DOGS:**
 - a) 1–2 mg/kg PO q12h (Fox 2003a), (Moise 2002)
 - b) 2–3 mg/kg PO q12h (Meurs 2002)
 - c) For ventricular tachycardia: 1–2 mg/kg PO twice daily (Atkins 2007a)
 - d) For ventricular tachycardias, supraventricular tachycardias: 1–2 mg/kg PO q12h (Smith 2007)
 - e) For ventricular tachyarrhythmias in Boxers in combination with mexiletine: Sotalol 1.5–3 mg/kg PO twice daily with mexiletine (5–7.5 mg/kg PO three times daily). (Prosek, Estrada et al. 2006)
- **CATS:**
 - a) 2 mg/kg PO twice daily (Atkins 2003b)

Monitoring

- Efficacy (ECG)
- Adverse effects

Client Information

- Relatively limited clinical experience; but appears safe
- Must be given as prescribed; do not stop drug suddenly or alter dosing without veterinarian guidance
- Report adverse effects to veterinarian immediately

Chemistry/Synonyms

A non-selective beta-blocker and Class III antiarrhythmic agent, sotalol HCl is a racemic mixture of the d- and l- forms. Both isomers exhibit antiarrhythmic (Class II) activity, but only the Levo- form has beta blocking activity. Sotalol HCl occurs as white, crystalline solid that is soluble in water.

Sotalol may also be known as: MJ-1999, d,l-sotalol hydrochloride, or sotaloli hydrochloridum; many trade names are available.

Storage/Stability

Store tablets at room temperature.

Dosage Forms/Approval

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Sotalol HCl Tablets: 80 mg, 120 mg, 160 mg & 240 mg; *Betapace*® & *Betapace*® AF (Berlex); generic; (Rx)

SPECTINOMYCIN HCL SPECTINOMYCIN SULFATE

(spek-ti-noe-mye-sin) Adspec®, Spectam®

AMINOCYCLITOL ANTIBIOTIC

Prescriber Highlights

- ▶ Aminocyclitol antibiotic used primarily in food producing animals; relatively broad spectrum but minimal activity against anaerobes & most strains of *Pseudomonas*
- ▶ Contraindications: Hypersensitive to it
- ▶ Adverse Effects: Appears to have minimal adverse effects at labeled dosages; probably less nephrotoxicity/ototoxicity than other aminocyclitols. Can cause neuromuscular blockade. May cause swelling at SC injection sites.

Uses/Indications

Although occasionally used in dogs, cats, and horses for susceptible infections, Spectinomycin only has approved dosage forms for cattle, chickens, turkeys, and swine. Refer to the Dosage section below for more information on approved uses.

Pharmacology/Actions

Spectinomycin is primarily a bacteriostatic antibiotic that inhibits protein synthesis in susceptible bacteria by binding to the 30S ribosomal subunit.

Spectinomycin has activity against a wide variety of gram-positive and gram-negative bacteria, including *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter*, *Salmonella*, *Streptococci*, *Staphylococcus*, and *Mycoplasma*. It has minimal activity against anaerobes, most strains of *Pseudomonas*, *Chlamydia*, or *Treponema*.

In human medicine, spectinomycin is used principally for its activity against *Neisseria gonorrhoeae*.

Pharmacokinetics

After oral administration only about 7% of the dose is absorbed, but the drug that remains in the GI tract is active. When injected SC or IM, the drug is reportedly absorbed well with peak levels occurring in about 1 hour.

Tissue levels of absorbed drug are lower than those found in the serum. Spectinomycin does not appreciably enter the CSF or the eye and is not bound significantly to plasma proteins. It is unknown whether spectinomycin crosses the placenta or enters milk.

Absorbed drug is excreted via glomerular filtration into the urine mostly unchanged. In cattle, terminal half-life is about 2 hours.

Contraindications/Precautions/Warnings

Spectinomycin is contraindicated in patients hypersensitive to it.

Adverse Effects

When used as labeled, adverse effects are unlikely with this drug. It is reported that parenteral use of this drug is much safer than with other aminocyclitol antibiotics, but little is known regarding its prolonged use. It is probably safe to say that spectinomycin is significantly less ototoxic and nephrotoxic than other commonly used aminocyclitol antibiotics, but can cause neuromuscular blockade. Parenteral calcium administration will generally reverse the blockade.

Adverse effects that have been reported in human patients receiving the drug in single or multidose studies include soreness at injection site, increases in BUN, alkaline phosphatase and SGPT, and decreases in hemoglobin, hematocrit, and creatinine clearance. Although increases in BUN and decreases in creatinine clearance and urine output have been noted, overt renal toxicity has not been demonstrated with this drug.

Cattle receiving the sulfate form subcutaneously have developed swelling at the injection site.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *B* for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether spectinomycin is excreted in milk; use caution when administering to nursing patients.

Overdosage/Acute Toxicity

No specific information was located on oral overdoses, but because the drug is negligibly absorbed after oral administration, significant toxicity is unlikely via this route.

Injected doses of 90 mg produced transient ataxia in turkey poults.

Drug Interactions

- Antagonism has been reported when spectinomycin is used with **chloramphenicol** or **tetracycline**.

Doses

■ DOGS:

For susceptible infections:

- a) 5.5–11 mg/kg q12h IM or 22 mg/kg PO q12h (for enteric infections; not absorbed) (Kirk 1989)
- b) 5–10 mg/kg IM q12h (Davis 1985)
- c) For acute infectious gastroenteritis: 5–12 mg/kg IM q12h (DeNovo 1986)

■ CATS:

For susceptible infections:

- a) For acute infectious gastroenteritis: 5–12 mg/kg IM q12h (DeNovo 1986)

■ CATTLE:

For susceptible infections:

- a) For bronchopneumonia and fibrinous pneumonia: 33 mg/kg SC q8h. Suggested withdrawal time is 60 days. (Hjerpe 1986)
- b) 22–39.6 mg/kg/day IM divided three times daily (Upson 1988)
- c) For bovine respiratory disease: 10–15 mg/kg SC (in the neck; not more than 50 mL per site) once daily (q24h) for 3–5 consecutive days (Label directions; *Adspec*®)

■ HORSES:

For susceptible infections:

- 20 mg/kg, IM three times daily (Robinson 1987)
- For pneumonia: 20 mg/kg IM q8h; may cause local myositis. Insufficient data to comment on use. (Beech 1987b)

■ SWINE:

For susceptible enteric infections:

- 10 mg/kg, PO q12h (Howard 1986)
- For bacterial enteritis (white scours) in baby pigs associated with *E. coli* susceptible to spectinomycin: 50 mg/10 lbs of body weight PO twice daily for 3–5 days (Label directions; *Spectam Scour-Halt*®—Ceva)
- 10 mg/kg, IM q12h (Baggot 1983)

■ BIRDS:

- For airsacculitis associated with *M. meleagridis* or chronic respiratory disease associated with *E. coli* in turkey poults (1–3 days old): Inject 0.1 mL (10 mg) SC in the base of the neck.

For control and to lessen mortality due to infections from *M. synoviae*, *S. typhimurium*, *S. infantis*, and *E. coli* in newly hatched chicks: Dilute injection with normal saline to a concentration of 2.5–5 mg/0.2 mL and inject SC. (Label directions; *Spectam*® *Injectable*—Ceva)

- For prevention and control of chronic respiratory disease associated with *Mycoplasma gallisepticum* in broilers: Add sufficient amount to drinking water to attain a final concentration of 2 g/gallon.

For infectious synovitis associated with *Mycoplasma synoviae* in broilers: Add sufficient amount to drinking water to attain a final concentration of 1 g/gallon.

For improved weight gain/feed efficiency in floor-raised broilers: Add sufficient amount to drinking water to attain a final concentration of 0.5 g/gallon. (Label directions; *Spectam*® *Water-Soluble*—Ceva)

Monitoring

- Clinical efficacy

Chemistry/Synonyms

An aminocyclitol antibiotic obtained from *Streptomyces spectabilis*, spectinomycin is available as the dihydrochloride pentahydrate and hexahydrate sulfate salts. It occurs as a white to pale buff, crystalline powder with pK_{as} of 7 and 8.7. It is freely soluble in water and practically insoluble in alcohol.

Spectinomycin may also be known as: M-141, actinospectacin, spectinomycini, U-18409AE, *Adspec*®, *Amtech Spectam*®, *Kempi*®, *Kirin*®, *Spectoguard Scour-Chek*®, *Stanilo*®, *Togamycin*®, *Trobicin*®, *Trobicine*®, or *Vabicin*®.

Storage/Stability

Unless otherwise instructed by the manufacturer, spectinomycin products should be stored at room temperature (15–30°C). Protect from freezing.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Spectinomycin Sulfate Injection: 100 mg/mL in 500 mL vials; *Adspec*®; (Pharmacia & Upjohn); (Rx). When used as labeled, slaughter withdrawal in cattle = 11 days; not to be used in veal calves or in dairy cattle 20 months of age or older.

Spectinomycin Injection: 100 mg/mL in 500 mL vials; *Amtech Spectam*® *Injectable* (IVX); (OTC). Approved for use in 1–3 days old turkey poults and newly hatched chicks.

Spectinomycin Water Soluble Concentrate: 0.5 g of spectinomycin per gram *Spectam*® *Water Soluble* (Bimeda); (OTC). Approved for use in chickens (not layers). Slaughter withdrawal (at labeled doses) = 5 days.

Spectinomycin Oral Solution: 50 mg/mL in 240 mL pump bottle and 500 and 1000 mL without pump; *Amtech Spectam Scour-Halt*®, (IVX), *Spectoguard Scour-Chek*® (Bimeda), *Spectam Scour-Halt*®, (AgriPharm); (OTC). Approved for use in swine (Weighing less than 15 lbs and not older than 4 weeks of age). Slaughter withdrawal (at labeled doses) = 21 days.

Spectinomycin/Lincomycin in a 2:1 ratio

LS 50 Water Soluble Powder® (Pharmacia & Upjohn); *Sepclinx-50*® (Bimeda); generic (IVX, AgriLabs); in 2.65 oz packets. Each packet contains lincomycin 16.7 g and spectinomycin 33.3 g. Approved for use in chickens up to 7 days of age.

Lincomycin 50 mg/Spectinomycin 100 mg per mL in 20 mL vials; *Linco-Spectin*® *Sterile Solution* (Pharmacia & Upjohn); (OTC). Approved for use in semen extenders only.

HUMAN-LABELED PRODUCTS:

Spectinomycin Powder for Injection: 400 mg (as the HCl) per mL after reconstitution in 2 g vial with 3.2 mL diluent; *Trobicin*® (Upjohn); (Rx)

SPIRONOLACTONE

(speer-on-oh-lak-tone) Aldactone®

ALDOSTERONE ANTAGONIST**Prescriber Highlights**

- Aldosterone antagonist used as a potassium sparing diuretic or for adjunctive treatment for heart failure (use is somewhat controversial for CHF in dogs); should not be substituted for furosemide in CHF
- Contraindications: Hyperkalemia, Addison's disease, anuria, acute renal failure or significant renal impairment
- Caution: Any renal impairment or hepatic disease
- Adverse Effects: Hyperkalemia, hyponatremia, & dehydration; increased BUN & mild acidosis in patients with renal impairment. GI distress (vomiting, anorexia, etc.), CNS effects (lethargy, ataxia, headache, etc.), & endocrine changes possible

Uses/Indications

Spironolactone may be used in patients with congestive heart failure who do not adequately respond to furosemide and ACE inhibitors, who develop hypokalemia on other diuretics, and are unwilling or unable to supplement with exogenous potassium sources. It may also be effective in treating ascites as it has less potential to increase ammonia levels than other diuretics.

Pharmacology/Actions

Aldosterone is competitively inhibited by spironolactone in the distal renal tubules with resultant increased excretion of sodium, chloride, and water, and decreased excretion of potassium, ammonium, phosphate, and titratable acid. Spironolactone has no effect on carbonic anhydrase or renal transport mechanisms and has its greatest effect in patients with hyperaldosteronism. When used alone in

healthy dogs, spironolactone does not appear to cause significant diuresis (Jeunesse, Wohrle et al. 2004).

Spironolactone is not commonly used alone as most sodium is reabsorbed at the proximal tubules. Combining it with a thiazide or loop diuretic will yield maximum diuretic effect.

After cats received 2.7 mg/kg spironolactone twice daily for 7–9 days, the following serum values increased (on average) significantly: potassium 0.39 mEq/L, calcium 0.48 mg/dL, creatinine 0.22 mg/dL, phosphorus 0.63 mg/dL and total protein 0.51 mg/dL. (Abbott and Saker 2006)

In humans, spironolactone can have antifibrotic effects on cardiac muscle.

Pharmacokinetics

No information was found regarding the pharmacokinetics of spironolactone in veterinary species. In humans, spironolactone is >90% bioavailable and peak levels are reached within 1–2 hours. The diuretic action of spironolactone (when used alone) is gradually attained and generally reaches its maximal effect on the third day of therapy.

Spironolactone and its active metabolite, canrenone, are both about 98% bound to plasma proteins. Both spironolactone and its metabolites may cross the placenta. Canrenone has been detected in breast milk. Spironolactone is rapidly metabolized (half-life of 1–2 hours) to several metabolites, including canrenone, which has diuretic activity. Canrenone is more slowly eliminated, with an average half-life of around 20 hours.

Contraindications/Precautions/Warnings

Spironolactone is contraindicated in patients with hyperkalemia, Addison's disease, anuria, acute renal failure or significant renal impairment. It should be used cautiously in patients with any renal impairment or hepatic disease.

Adverse Effects

Adverse effects are usually considered mild and reversible upon discontinuation of the drug. Electrolyte (hyperkalemia, hyponatremia) and water balance (dehydration) abnormalities are the most likely effects with spironolactone therapy, but electrolytes in dogs do not appear to be significantly affected.

Transient increases in BUN and mild acidosis may occur in patients with renal impairment. GI distress (vomiting, anorexia, etc.), CNS effects (lethargy, ataxia, headache, etc.), and endocrine changes (gynecomastia in human males) are all possible.

Use of spironolactone in patients with renal impairment may lead to hyperkalemia. Spironolactone reportedly inhibits the synthesis of testosterone and may increase the peripheral conversion of testosterone to estradiol. Long-term toxicity studies in rats have demonstrated that spironolactone is tumorigenic in that species.

Reproductive/Nursing Safety

Spironolactone or its metabolites may cross the placental barrier. Feminization occurs in male rat fetuses. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Canrenone, a metabolite of spironolactone, appears in maternal milk. In humans, the estimated maximum dose to the infant is approximately 0.2% of the mother's daily dose. Use with caution in nursing patients, but it is unlikely of clinical significance in veterinary patients.

Overdosage/Acute Toxicity

Information on overdosage of spironolactone is apparently unavailable. Should an acute overdose occur, it is suggested to follow the guidelines outlined in the chlorothiazide and furosemide monographs. Contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving spironolactone and may be of significance in veterinary patients:

- **DIGOXIN:** Spironolactone may increase the half-life of digoxin; enhanced monitoring of digoxin serum levels and effects are warranted when spironolactone is used with these agents
- **MITOTANE:** Spironolactone may mute the effects of mitotane if given concurrently, but very limited information is available on this potential interaction; monitor carefully.
- **NEUROMUSCULAR BLOCKERS, NON-DEPOLARIZING:** Increase in neuromuscular blockade effects possible
- **POTASSIUM-SPARING DIURETICS, OTHER** (e.g., **triamterene**): Hyperkalemia possible
- **POTASSIUM SUPPLEMENTS:** Hyperkalemia possible
- **SALICYLATES:** Spironolactone's diuretic effects may be decreased if **aspirin** or other salicylates are administered concomitantly

Laboratory Considerations

- Spironolactone may give falsely elevated **digoxin** values, if using a radioimmune assay (RIA) method.
- Fluorometric methods of determining plasma and urinary **17-hydroxycorticosteroids** (cortisol) may be interfered with by spironolactone.

Doses

■ DOGS:

As a diuretic in CHF:

- a) When furosemide and ACE inhibitors alone do not control fluid accumulation in refractory CHF: 1–2 mg/kg PO q12h (Ware and Keene 2000)
- b) With other diuretics when hypokalemia is an issue: 2–4 mg/kg PO once daily (Kittleson 2000)
- c) To allow further reduction of furosemide dose (target dose for furosemide during maintenance phase: 1–2 mg/kg PO q24–48h): Spironolactone dose varies between 0.5 mg/kg PO once daily (aldosterone blockage, weak diuretic effect) to 2 mg/kg twice daily (stronger diuretic effect). (de Madron 2004)

For treating ascites:

- a) 1–2 mg/kg PO twice daily; if no response in 4–5 days, double dose for an additional 4–5 days; if no response, may double again (4–8 mg/kg twice daily). Monitor (weigh) patients daily and do not allow patient to become dehydrated or to lose more than 0.25–0.5 kg/day. (Hardy 1985)
- b) Attempt at treating underlying abnormality. When ascites is caused by right-sided heart failure: Be sure owner is administering medication properly and the prescription is correct. Increase furosemide to 4–6 mg/kg PO q8h (generally speaking dose should be increased until all the abnormal accumulated fluid is eliminated or unacceptable azotemia develops). Optimize ACE inhibitor dose. Restrict dietary sodium. Add spironolactone at 1–2 mg/kg PO q12h. Initially (3 times weekly) substitute one of the oral furosemide doses with a SC dose. Consider adding hydrochlorothiazide initially at 2 mg/kg PO every other day. (Connolly 2006)

For adjunctive treatment of hypertension:

- a) 1–2 mg/kg PO q12h (Stepian 2006b)

■ **CATS:**

As a diuretic in CHF:

- a) When furosemide and ACE inhibitors alone do not control fluid accumulation in refractory CHF: 1–2 mg/kg PO q12h (Ware and Keene 2000)
b) 1 mg/kg q12h PO when serum potassium is low (Bonagura 1989)

For adjunctive treatment of hypertension:

- a) 1–2 mg/kg PO q12h (Stepian 2006b)

Monitoring

- Serum electrolytes, BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema/ascites; patient weight, if indicated

Client Information

- Notify veterinarian if GI symptoms (*e.g.*, vomiting, diarrhea, anorexia), lethargy, or other CNS effects are severe or persist

Chemistry/Synonyms

A synthetically produced aldosterone antagonist, spironolactone occurs as a cream-colored to light tan, crystalline powder with a faint mercaptan-like odor. It has a melting range of 198°–207°, with decomposition. Spironolactone is practically insoluble in water and soluble in alcohol.

Spironolactone may also be known as: espironolactona, SC-9420, spiro lactone, spironolactonum; many trade names are available.

Storage/Stability

Spironolactone tablets should be stored at room temperature in tight, light-resistant containers. An extemporaneously prepared oral suspension can be prepared by pulverizing commercially available tablets and adding cherry syrup. This preparation is reportedly stable for at least one month when refrigerated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Spironolactone Tablets: 25 mg, 50 mg & 100 mg; *Aldactone*® (Searle); generic; (Rx)

Also available in combination with hydrochlorothiazide.

STANOZOLOL

(stah-no-zo-lahl) Winstrol®-V

ANABOLIC STEROID

Prescriber Highlights

- Anabolic steroid; veterinary labeled products no longer marketed in USA
- Contraindications: Pregnant animals, breeding stallions, food animals. Extreme Caution: Cats, hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, & during the nephrotic stage of nephritis. Caution: Cardiac & renal dysfunction with enhanced fluid & electrolyte monitoring.
- Adverse Effects: Potentially high incidence of hepatotoxicity in cats. Other possible effects: sodium, calcium, potassium, water, chloride, & phosphate retention; hepatotoxicity, behavioral (androgenic) changes, & reproductive abnormalities (oligospermia, estrus suppression)
- Category “X” for pregnancy; teratogenicity outweighs any possible benefit
- Controlled substance in the USA
- Drug Interactions; lab interactions

Uses/Indications

Labeled indications for the previously marketed veterinary stanozolol product *Winstrol*®-V (Winthrop/Upjohn) included “...to improve appetite, promote weight gain, and increase strength and vitality...” in dogs, cats and horses. The manufacturer also stated that: “Anabolic therapy is intended primarily as an adjunct to other specific and supportive therapy, including nutritional therapy.”

Like nandrolone, stanozolol has been used to treat anemia of chronic disease. Because stanozolol has been demonstrated to enhance fibrinolysis after parenteral injection, it may be efficacious in the treatment of feline aortic thromboembolism or thrombosis in nephrotic syndrome; however, clinical studies and/or experience are apparently lacking for this indication at present.

Pharmacology/Actions

Stanozolol possesses the actions of other anabolic agents but it may be less androgenic than other anabolics that are used in veterinary medicine. Refer to the discussion in the boldenone monograph for more information.

Pharmacokinetics

No specific information was located for this agent. It is generally recommended that the injectable suspension be dosed on a weekly basis in both small animals and horses.

Contraindications/Precautions/Warnings

Stanozolol is contraindicated in pregnant animals and in breeding stallions and should not be administered to horses intended for food purposes. Because of reported hepatotoxicity associated with this drug in cats, it should only be used in this species with extreme caution.

The manufacturer recommends using stanozolol cautiously in patients with cardiac and renal dysfunction with enhanced fluid and electrolyte monitoring.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, benign prostatic hypertrophy, during the nephrotic stage of nephritis, and in selected patients with breast carcinoma.

Adverse Effects

The manufacturer (Winthrop/Upjohn) lists as adverse effects in dogs, cats, and horses only “mild androgenic effects” and then only when used with excessively high doses for a prolonged period of time.

One study in cats, demonstrated a very high incidence of hepatotoxicity associated with stanozolol use and the authors recommended that this drug not be used in cats until further toxicological studies are performed.

Potentially (from human data), adverse reactions of the anabolic agents in dogs and cats could include: sodium, calcium, potassium, water, chloride, and phosphate retention, hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (oligospermia, estrus suppression).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, use in nursing patients with extreme caution.

Overdosage/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving stanozolol and may be of significance in veterinary patients:

- **ANTICOAGULANTS** (**heparin, warfarin**): Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR/PT's and dosage adjustment, if necessary, of the anticoagulant are recommended
- **CORTICOSTEROIDS**: Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN**: Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements

Laboratory Considerations

- Concentrations of protein bound iodine (PBI) can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important. Androgen/anabolic agents can decrease amounts of thyroxine-binding globulin and decrease **total T₄** concentrations and increase resin uptake of **T₃** and **T₄**. Free thyroid hormones are unaltered and there is no evidence of dysfunction.
- Both **creatinine** and **creatinine** excretion can be decreased by anabolic steroids.

- Anabolic steroids can increase the urinary excretion of **17-keto-steroids**.
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress **clotting factors** II, V, VII, and X.
- Anabolic agents can affect **liver function tests** (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase).

Doses

■ DOGS:

As an anabolic agent per labeled indications:

- a) Small Breeds: 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly.

Large Breeds: 2–4 mg PO twice daily; or 50 mg deep IM, may repeat weekly.

Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

For anemia secondary to chronic renal failure:

- a) 1–4 mg PO once daily (Ross et al. 1988)
- b) For anemias secondary to uremia: 2–10 mg PO twice daily (Maggio-Price 1988)

As an anabolic/appetite stimulant:

- a) 1–4 mg PO twice daily (Weller 1988)
- b) 1–2 mg PO twice daily or 25–50 mg IM weekly (Macy and Ralston 1989), (Bartges 2003b)

For canine cognitive dysfunction:

- a) 2 mg/kg IM for 4–6 weeks with 1–2 mg (total dose) PO once daily for dogs less than 23 kg and 4 mg (total dose) PO once daily for dogs greater than 23 kg. If drug has some positive effect, maintain oral dosing and gradually reduce injections to every 3–4 weeks. (Hoskins 1999)

■ CATS: Note: See Warnings Above

As an anabolic agent per labeled indications:

- a) 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly. Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

■ FERRETS:

- a) 0.5 mg/kg PO or SC twice daily; use with caution in hepatic disease (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: As an appetite stimulant: 0.5–2 mg PO once (Ivey and Morrissey 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

As an anabolic agent per labeled indications:

- a) 0.55 mg/kg (25 mg per 100 pounds of body weight) IM deeply. May repeat weekly for up to and including 4 weeks. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

■ SHEEP & GOATS:

For acute or subacute aflatoxicosis in ruminants:

- a) Stanozolol 2 mg/kg IM (plus activated charcoal 6.7 mg/kg as a 30% w/v slurry in M/15, pH 7 phosphate buffer). Do not combine with oxytetracycline therapy. (Hatch 1988)

■ BIRDS:

As an anabolic agent to promote weight gain and recovery from disease:

- a) 0.5–1 mL/kg (25–50 mg/kg) IM once or twice weekly. Use with caution in birds with renal disease. (Clubb 1986)

■ REPTILES:

For most species post-surgically and in very debilitated animals:
a) 5 mg/kg IM once a week as needed (Gauvin 1993)

Monitoring

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- RBC count, indices, if indicated
- Weight, appetite

Client Information

- Tablets may be crushed and administered with food
- Because of the potential for abuse of anabolic steroids this agent is a controlled drug; it should be kept in a secure area and out of the reach of children

Chemistry/Synonyms

An anabolic steroid, stanozolol occurs as an odorless, nearly colorless, crystalline powder that can exist in two forms: prisms that melt at approximately 235°C, and needles that melt at about 155°C. It is sparingly soluble in alcohol and insoluble in water.

Stanozolol may also be known as: androstanazole, estanozolol, methylstanazole, NSC-43193, stanozololum, win-14833, *Menabol*®, *Neurabol*®, *Stanol*®, *Stromba*®, *Strombaject*® and *Winstrol*®.

Storage/Stability

Stanozolol tablets should be stored in tight, light-resistant packaging, preferably at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

Winstrol®-V (Pfizer) tablets and injection were previously available.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Stanozolol Oral Tablets: 2 mg (scored); *Winstrol*® (Winthrop Pharm.); (Rx, C-III)

STAPHYLOCOCCAL PHAGE LYSATE

(*staf-loe-kok-al fajē lye-sate*) Staphage Lysate (SP)®, SPL
IMMUNE STIMULANT

Prescriber Highlights

- ▶ Injectable immune stimulant used to treat dogs with recurrent, idiopathic, staphylococcal pyodermas
- ▶ May cause hypersensitivity (local or systemic)

Uses/Indications

Staphylococcal phage lysate (SPL) is labeled for treatment of canine pyoderma and related staphylococcal hypersensitivity, or polymicrobial skin infections with a staphylococcal component. Veterinary dermatologists use SPL most commonly to treat recurrent, idiopathic, staphylococcal pyodermas in combination (at least initially) with an appropriate antibiotic.

Pharmacology/Actions

SPL apparently enhances cell-mediated immunity. It stimulates the production of tumor necrosis factor, interleukin-6, interleukin- γ , and γ -interferon.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

The label states that “there are no known contraindications to the use of *SPL*® except that in highly allergic patients, reduced desensitizing doses may be indicated.” However, use with extreme caution, if at all, in patients with prior systemic hypersensitivity reactions to it or documented hypersensitivity reactions to beef products (contains unfiltered beef heart infusion broth).

Avoid administering subsequent doses at the same injection site.

The product contains no preservative so it must be handled aseptically. It is recommended to use the entire contents when the vial is opened.

Adverse Effects

Adverse effects reported for SPL include post vaccine-type reactions (fever, malaise, etc.) and injection site reactions (redness, itching, swelling) that may occur in 2–3 hours after injection and persisting up to 3 days. If these effects are excessive, the manufacturer recommends dosage reduction.

Systemic hypersensitivity reactions are thought to occur rarely. Signs could include weakness, vomiting, diarrhea, severe itching, rapid breathing, and/or fatigue/lassitude. Should an anaphylactic-type reaction occur, treat supportively; the manufacturer recommends epinephrine and atropine as antidotes.

Reproductive/Nursing Safety

Studies performed in rats and rabbits demonstrated no impaired fertility or fetal harm.

No information was located on safety during nursing, but it is unlikely to be of concern.

Overdosage/Acute Toxicity

No specific information was located. Other than an increased risk for local or systemic hypersensitivity reactions, significant morbidity appears unlikely.

Drug Interactions

- **CELL-MEDIATED IMMUNOSUPPRESSIVE DRUGS** (e.g., corticosteroids, cyclosporine): These drugs may reduce the efficacy of SPL

Laboratory Considerations

No significant concerns noted.

Doses

■ DOGS:

- a) For labeled indications: Highly allergic patients: Skin test with 0.05–0.1 mL intradermally. Therapy: Initially, 0.2 mL SC, then incremental increases of 0.2 mL once a week to 1 mL (a total of 5 injections). Then continue at 1 mL SC weekly for approximately 10–12 weeks.

For non-allergic patients: 0.5 mL SC twice weekly for 10–12 weeks, then 0.5–1 mL every 1–2 weeks.

Concomitant antibiotic therapy is recommended for an initial 4–6 week period.

Maximum dose should be decreased in small dogs and can be increased cautiously, if necessary, in large dogs to 1.5 mL. This dose is continued until improvement is demonstrated

then the interval may be lengthened gradually to the longest interval that maintains adequate clinical control. (Label information; *Staphage Lysate (SPL)*®—Delmont Labs)

- b) For idiopathic, recurrent pyoderma: Typically given 0.5 mL SC twice weekly for 10–12 weeks, then tapered to effect. This agent is rarely needed, because in most cases, an underlying cause can be identified and treated. (Gram 2005)

Monitoring

- Clinical efficacy
- Local and systemic reactions (see adverse effects)

Client Information

- This medication should ideally be administered at a veterinary practice where suitable treatment can be instituted should a serious adverse effect (e.g., anaphylaxis) occur
- Report to veterinarian any adverse effects noted (e.g., local effects at injection site, itching, change in behavior or activity level, difficulty or unexplained rapid breathing, vomiting, diarrhea)

Chemistry/Synonyms

SPL is prepared by lysing cultures of *Staphylococcus aureus* (Cowan serologic types I & III; human strains) by a staphylococcal bacteriophage. Pre-lysed cell counts (120–180 CFU/mL) are used to standardize the product; ultrafiltration achieves bacteriologic sterility. The prepared solution contains *Staphylococcus aureus* components (protein A extracts), bacteriophage, and unfiltered beef heart infusion.

Storage/Stability/Compatibility

SPL should be stored in the refrigerator (2–7°C); do not freeze.

Unopened, properly stored vials and ampules have an average expiration date of one year past the shipment date. The product contains no preservative and must be handled aseptically. It is recommended using the entire contents of the vial after opening. Do not use if contents are cloudy.

Do not mix with other drugs or solutions prior to administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Staphylococcal Phage Lysate (serotypes I & III): in 1 mL ampules (box of 10) and 10 mL multi-dose vials (no preservative added and manufacturer recommends using entire contents when opened); *Staphage Lysate (SPL)*® (Delmont Labs); (Biologic OTC)

Note: This product is a USDA-licensed biologic and is not an FDA-approved product.

HUMAN-LABELED PRODUCTS: None

STREPTOKINASE

(strep-toe-kin-ase) Streptase®

THROMBOLYTIC

Prescriber Highlights

- Used for serious thromboembolic disease in dogs
- May be contraindicated in cats; use is controversial in this species
- Adverse Effects (most frequent/serious): Hemorrhage, hyperkalemia, fever, & allergic reactions
- Expensive
- Patient must be intensively monitored

Uses/Indications

Streptokinase may be useful for the adjunctive treatment of serious thromboses. The use of thrombolytics (streptokinase, t-PA) in cats is controversial.

Pharmacology/Actions

Streptokinase promotes thrombolysis via a complex mechanism; put simply, streptokinase helps convert plasminogen into plasmin. Plasmin then degrades fibrin and fibrinogen to lyse thrombi.

Pharmacokinetics

After IV injection, streptokinase is cleared from the circulation rapidly via the reticuloendothelial system and by circulating antibodies.

Contraindications/Precautions/Warnings

Streptokinase is contraindicated in severe hypertension, internal bleeding, trauma within the past month, or when the risks of hemorrhage outweigh the benefits of therapy.

Streptokinase use is controversial in cats and many clinicians believe it is contraindicated in this species. While the drug has been used without mortality under research conditions, lack of efficacy in the laboratory and high rates of death in clinical settings have occurred.

Streptokinase therapy in veterinary medicine should be reserved for those hospitals where adequate monitoring is available (Heme/coag lab) and having clinical experience in managing serious thrombotic and coagulation disorders.

Adverse Effects

The most severe and frequently reported adverse effects associated with streptokinase therapy in dogs are hemorrhage, fever, hyperkalemia, and allergic reactions. Additionally, hypotension, arrhythmias, and phlebitis at the site of the injection have been noted.

In cats, thrombolytic therapy has been associated with a high mortality and morbidity. Hyperkalemia, acidosis, mild hemorrhage, and fever have been reported in cats.

Streptokinase resistance has been reported in humans, particularly after a recent Streptococcal infection or if previous streptokinase therapy has been given. If thrombin time or other factors associated with lysis have not changed after 4 hours of therapy, it is recommended to discontinue therapy.

Reproductive/Nursing Safety

It is unknown if streptokinase can cause fetal harm. The drug may cause premature separation of the placenta if administered during the first half of pregnancy. Streptokinase apparently does not cross

the placenta, but antibodies to it do. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

See Adverse Effects above. Treating severe spontaneous bleeding may include: discontinuing streptokinase infusions and giving plasma volume expanders (dextran, hetastarch, and packed RBC's). In an emergency situation, aminocaproic acid may be considered to reduce the fibrinolytic state. Doses for humans are: loading dose of 5 grams (IV or PO) followed by 1 gram per hour for 2–4 hours.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving streptokinase and may be of significance in veterinary patients:

- **AMINOCAPROIC ACID:** May reverse the fibrinolytic effects of streptokinase
- **HEPARIN, WARFARIN:** Other anticoagulants are often used in conjunction with streptokinase, but may increase the likelihood of bleeding; adequate monitoring is essential

Laboratory Considerations

- IV streptokinase will significantly decrease **plasminogen** and **fibrinogen**, and increase **TT**, **aPTT** and **PT**.

Doses

■ DOGS:

For the treatment of serious thrombosis:

- a) 90,000 IU IV over 1/2 hour followed by a constant rate infusion of 45,000 IU per hour for 7–12 hours. Must also specifically treat primary disease process and give supportive care to correct hypoxemia and loss of tissue perfusion. (Brooks 2000)
- b) 15,000–18,000 U/kg IV as a loading dose, followed by a maintenance dose of 45,000 U/hr for up to 12 hours. Use only if hemodynamically stable. (Kramer 2003b)
- c) For pulmonary thromboembolism: 90,000 IU IV over 30 minutes followed by a constant rate infusion of 45,000 IU per hour for 6–12 hours until respiration/hypoxemia improves. (Macintire 2006c)

■ CATS:

Note: Thrombolytic therapy in cats is controversial. Use with extreme caution.

For thrombolytic treatment of serious thrombosis:

- a) 90,000 IU IV over 20 minutes followed by a constant rate infusion of 45,000 IU for 2–24 hours (Fox 2003b), (Fox 2007a)

Monitoring

Monitoring essential:

- Coagulation status: hemorrhage, serial fibrinogen, fibrin degradation products
- Blood pressure
- Serum potassium
- Clinical status (including temperature)

Chemistry/Synonyms

Produced by group C Beta-hemolytic streptococci, streptokinase is commercially available as a lyophilized white powder. It is freely soluble in water.

Streptokinase may also be known as: estreptoquinasa, plasminokinase, streptokinasum, *Kabikinase*®, *Streptase*®, *Streptonase*®, *Unitinase*®, or *Zykinase*®.

Storage/Stability

The powder should be stored at room temperature. Because they contain no preservatives, ideally, streptokinase solutions should be used immediately after reconstitution. If administration is delayed, refrigerate the solution and use within 24 hours. Do not mix with dextran solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Streptokinase Powder for Injection lyophilized: 250,000 IU, 750,000 IU or 1.5 million IU preservative-free in 6 mL vials and 50 mL infusion bottles; *Streptase*® (Aventis Behring); (Rx)

STREPTOZOCIN

(strep-toe-zoe-sin) Zanosar®

ANTINEOPLASTIC

Prescriber Highlights

- Antineoplastic used primarily for treating recurrent insulinoma in dogs
- May be nephrotoxic, myelotoxic, hepatotoxic
- Vomiting after treatment may occur
- To reduce nephrotoxicity, must give saline diuresis during administration

Uses/Indications

At present the primary purpose for streptozocin use in veterinary medicine is as a treatment for insulinomas in dogs, particularly those with refractory hypoglycemia and when tumors are non-resectable or have metastasized. Streptozocin potentially could be used for other oncologic conditions as well.

Pharmacology/Actions

While streptozocin has activity against gram-positive and gram-negative bacteria, its cytotoxicity prevents it from clinical usefulness for this purpose. While its antineoplastic activity is not well understood, streptozocin is considered an alkylating agent and it inhibits DNA synthesis, probably by inhibiting precursor incorporation into DNA.

Streptozocin also exhibits a species-specific (in dogs, not humans) diabetogenic effect via reducing nicotinamide adenine dinucleotide (NAD) concentration in pancreatic beta cells. This effect is usually irreversible in animals with preexisting normal beta cell function.

Pharmacokinetics

Streptozocin must be administered IV. Its distribution characteristics are not well known, but the drug does distribute to most tissues; concentrations in the pancreas are higher than those found in plasma. Streptozocin is metabolized, probably in the liver. Both unchanged and metabolized drug are excreted in the urine.

Contraindications/Precautions/Warnings

Should be used for recurrent insulinoma only in dogs that have undergone previous surgery in which all of the tumor could not be resected. Confirmed histologic diagnosis is mandatory.

Streptozocin must be used with extreme caution in patients with decreased renal, bone marrow, or hepatic function.

Adverse Effects

The primary concern when used for treating insulinomas in dogs is the potential for the development of serious, permanent renal toxicity. Aggressive saline diuresis during drug administration appears to reduce this concern. Additionally, GI effects (vomiting/nausea) often occur and can be severe or protracted. Less commonly, hematologic changes (mild myelosuppression) and increases in liver enzymes can occur. Injection site reactions (including severe necrosis) may occur if the drug extravasates.

Reproductive/Nursing Safety

Streptozocin has been shown to be teratogenic in rats; use during pregnancy when the benefits outweigh the risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether streptozocin is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if used in nursing patients.

Overdosage/Acute Toxicity

Severe toxicity may result if acutely overdosed (see Adverse Effects); calculate dosages carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving streptozocin and may be of significance in veterinary patients:

- **DOXORUBICIN:** Streptozocin may prolong the half-life of doxorubicin; dosage adjustment may be required
- **MYELOSUPPRESSIVE DRUGS, OTHER:** When streptozocin is used with other myelosuppressive drugs (e.g., **carmustine**) additive or synergistic myelosuppression may occur
- **NEPHROTOXIC DRUGS, OTHER (aminoglycosides, amphotericin B, cisplatin, etc.):** May cause additive nephrotoxicity when used with streptozocin
- **NIACINAMIDE (nicotinamide):** Can block the diabetogenic effects of streptozocin without altering its antineoplastic activity; this may be beneficial or detrimental depending on the reason for use

Doses

■ DOGS:

- a) For “investigational” treatment of recurrent insulinoma after surgery: Begin saline diuresis: Give normal saline at 18–20 mL/kg/hour for 7–8 hours. Over the 4th–5th hour, give streptozocin in the saline solution at a dose of 500 mg/m² IV. Give an antiemetic (e.g., butorphanol) at the end of the 7-hour period. (Meleo and Caplan 2000)
- b) Normal saline is given IV at 18.3 mL/kg/hr for 3 hours, then streptozocin is administered at 500 mg/m² over two hours with the saline diuresis continuing. After streptozocin infusion completed, continue saline diuresis for another 2 hours. Butorphanol is administered as an antiemetic immediately after streptozocin. May repeat at 3 week intervals until evidence of tumor progression, recurrence of hypoglycemia, or drug toxicity. Monitor for myelosuppression and nephrotoxicity. (Moore, Nelson et al. 2002)

Monitoring

- Blood glucose (efficacy)
- Baseline renal function tests (including urinalyses) and after treatment
- CBC
- Baseline liver function tests and before retreatment
- Hydration status (especially for the first few days after treatment or if vomiting a problem).

Client Information

- Clients should understand the “experimental” nature of this treatment and the potential risks for serious adverse effects; follow-up monitoring is essential.

Chemistry/Synonyms

Streptozocin is an antineoplastic antibiotic produced by *Streptomyces achromogenes*, although the commercial product is prepared synthetically. It occurs as an ivory colored, crystalline powder. It is very soluble in water and has a pKa of 1.35.

Streptozocin may also be known as: NSC-85998, streptozotocin, U-9889 and *Zanosar*®.

Storage/Stability

The lyophilized powder for injection should be stored in the refrigerator and protected from light. It is stable for at least 3 years after manufacture. If stored at room temperature, it is stable for at least one year after manufacture.

After reconstitution, the lyophilized powder for injection has a pH of 3.5–4.5. Dextrose 5% or 0.9% sodium chloride are used to reconstitute the solution. Citric acid is added to buffer the solution at a concentration of 22 mg/mL. The solution is stable for 48 hours at room temperature and 96 hours if refrigerated, but as no preservative is added the manufacturer recommends using the drug within 12 hours of mixing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Streptozocin Powder for Injection: 1 gram (100 mg/mL) in vials; *Zanosar*® (Genesia Sicor); (Rx)

SUCCIMER

(*sux-i-mer*) Chemet®, DMSA, Dimercaptosuccinic acid

ANTIDOTE; CHELATOR

Prescriber Highlights

- Oral heavy metal chelator
- Appears to be safe & effective despite limited experience
- Most likely adverse effects noted are GI in nature; may also cause increased liver enzymes, rash
- High doses may be fatal in birds
- Unpleasant odor of capsules; may give feces, urine, saliva, etc. a very unpleasant smell
- Cost is an issue

Uses/Indications

In veterinary medicine, succimer may be useful for the oral treatment of lead poisoning in small animals (including birds). Potentially, it also may be of benefit for the treatment of other toxic heavy metals such as arsenic or mercury, but more research must be done before this can be recommended.

Pharmacology/Actions

Succimer physically chelates heavy metals such as lead, mercury, and arsenic. These water-soluble chelates are then excreted via the kidneys.

Pharmacokinetics

No veterinary information was located. In humans, the drug is rapidly absorbed after oral ingestion, but only incompletely. Absorbed drug is excreted primarily through the kidneys into the urine. Half-life in humans is about 2 days.

Contraindications/Precautions/Warnings

Succimer is contraindicated in patients hypersensitive to it. Chelation therapy should only be attempted if the source of lead is removed to prevent further exposure.

Adverse Effects

Most common adverse reactions reported in humans are GI related effects (vomiting, diarrhea, etc.) or “flu-like” symptoms (body aches, fatigue, etc.). Increases in liver enzymes and rashes have also been reported.

Reproductive/Nursing Safety

It is unknown if succimer is safe to use during pregnancy. At high doses it was fetotoxic and teratogenic in mice. Mothers are discouraged from nursing when taking succimer. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in breast milk. Discourage mothers requiring therapy from nursing their infants.

Overdosage/Acute Toxicity

In toxicology studies, doses of up to 200 mg/kg per day in dogs did not cause overt toxicity. Doses of 300 mg/day did cause fatalities in dogs; primarily kidney and GI tract lesions were seen. Doses of 80 mg/kg, PO q12h did cause a significant number of fatalities in Cockatiels (but 40 mg/kg q12h did not). If an overdose situation is encountered, standardized gut evacuation with subsequent activated charcoal protocols are recommended.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succimer and may be of significance in veterinary patients:

- **CHELATING AGENTS, OTHER** (CaEDTA, dimercaprol, trientine, penicillamine, etc.): Concomitant use with other chelating agents is not recommended in humans

Laboratory Considerations

- False positive **urine ketones** can be reported when using nitroprusside reagents (e.g., as in *Ketostix*®)
- Falsely low measurements of **CPK** or serum **uric acid** can be caused by succimer

Doses

■ DOGS:

For lead poisoning:

- a) 10 mg/kg, PO q8h for 10 days (Sisson 2000)
- b) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

■ CATS:

For lead poisoning:

- a) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

■ BIRDS:

For lead poisoning:

- a) 15–35 mg/kg PO twice daily for 5 days (Calvert and Mieurs 2000)
- b) 30 mg/kg PO twice daily for a minimum of 7 days. If severe neurologic signs, may supplement with one dose of CaEDTA (edetate calcium disodium; <50 mg/kg of body weight IM) (Hoogesteijn, Raphael et al. 2003)

Monitoring

- Blood lead
- GI adverse effects
- Liver enzymes (AST, ALT)

Client Information

- Capsules may have an unpleasant odor; this is no problem with the drug, but unpleasant odor may be transferred to saliva, urine, feces
- Contents of capsules may be sprinkled on soft food
- Animals must be adequately hydrated as the lead chelates are excreted in the urine

Chemistry/Synonyms

A heavy metal chelating agent also known as meso-2,3 dimercaptosuccinic acid (DMSA), succimer is an analog of dimercaprol. It has an unpleasant odor.

Succimer may also be known as: meso-2,3 dimercaptosuccinic acid, dimercaptosuccinic acid, DIM-SA, DMSA, *Chemet*® or *Succinaptal*®.

Storage/Stability

Unless otherwise labeled, store succimer capsules in tight containers at room temperature. Protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Succimer Capsules: 100 mg; *Chemet*® (Ovation); (Rx)

SUCCINYLCHOLINE CHLORIDE

(suks-sin-i-nil-koe-leen) Anectine®

NEUROMUSCULAR BLOCKING AGENT

Prescriber Highlights

- ▶ Depolarizing neuromuscular blocking agent
- ▶ **Contraindications:** Severe liver disease, chronic anemias, malnourishment, glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, & increased CPK values with resultant myopathies
- ▶ **Extreme Caution:** Traumatic wounds or burns, receiving quinidine or digoxin therapy, hyperkalemia or electrolyte imbalances
- ▶ **Caution:** Pulmonary, renal, cardiovascular, metabolic or hepatic dysfunction
- ▶ **Adverse Effects:** Muscle soreness, histamine release, malignant hyperthermia, excessive salivation, hyperkalemia, rash, & myoglobinemia/myoglobinuria. Cardiovascular effects, (bradycardia, tachycardia, hypertension, hypotension, or arrhythmias)
- ▶ **Specific recommendations for use in horses** (see Contraindications below)
- ▶ **No analgesic or anesthetic effects**

Uses/Indications

Succinylcholine chloride is indicated for short-term muscle relaxation needed for surgical or diagnostic procedures, to facilitate endotracheal intubation in some species, and reducing the intensity of muscle contractions associated with electro- or pharmacological-induced convulsions. Dogs, cats, and horses are the primary veterinary species where succinylcholine chloride has been used.

Pharmacology/Actions

An ultrashort-acting depolarizing skeletal muscle relaxant, succinylcholine bonds with motor endplate cholinergic receptors to produce depolarization (perceived as fasciculations). The neuromuscular block remains as long as sufficient quantities of succinylcholine remain, and is characterized by a flaccid paralysis. Other pharmacologic effects are discussed in the precautions and adverse effects sections.

Pharmacokinetics

The onset of action, with complete muscle relaxation, after IV administration is usually within 30–60 seconds. In humans, this effect lasts for 2–3 minutes and then gradually diminishes within 10 minutes. The very short duration of action after a single IV dose is thought to occur because the drug diffuses away from the motor end plate. If multiple injections or a continuous infusion is performed, the brief activity is a result of rapid hydrolysis by pseudocholinesterases at the site of action. After IM injection, the onset of action is generally within 2–3 minutes and may persist for 10–30 minutes. Dogs exhibit a prolonged duration of action (\approx 20 minutes); this species appears unique in this idiosyncratic response.

Succinylcholine is metabolized by plasma pseudocholinesterases to succinylmonocholine and choline; 10% is excreted unchanged in the urine. Succinylmonocholine is partially excreted in the urine and may accumulate in patients with impaired renal function. Succinylmonocholine has approximately 1/20th the neuromuscu-

lar blocking activity of succinylcholine, but if it accumulates, prolonged periods of apnea may result.

Contraindications/Precautions/Warnings

Succinylcholine is contraindicated in patients with severe liver disease, chronic anemias, malnourishment (chronic), glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, and increased CPK values with resultant myopathies. As succinylcholine can exacerbate the effects of hyperkalemia, it should be used with extreme caution in patients who have suffered traumatic wounds or burns, are receiving quinidine or digoxin therapy, or have preexisting hyperkalemia or electrolyte imbalances as arrhythmias or cardiac arrest may occur. It should be used with caution in patients with pulmonary, renal, cardiovascular, metabolic, or hepatic dysfunction.

Succinylcholine should not be used if organophosphate agents have been given or applied recently.

Succinylcholine chloride does not have analgesic effects; and should be used with appropriate analgesic, sedative, and anesthetic agents.

In horses, The American Association of Equine Practitioners have made the following additional recommendations:

- 1) Inform the owner that succinylcholine chloride is to be used as a restraining agent, not as an anesthetic.
- 2) Obtain history before use; do not use in horses if within 30 days they have received, an antibiotic ending in “mycin”, organophosphate insecticides or anthelmintics, any other cholinesterase inhibitor, or procaine.
- 3) Do not use in debilitated, excited, or exhausted horses.
- 4) If possible, withhold food for 4–6 hours before use.
- 5) Dosage of 0.088 mg/kg IV may be used to paralyze skeletal muscles without causing respiratory depression. Higher doses may cause apnea and death without respiratory support. Lower doses may be possible if used with a preanesthetic agent.
- 6) After administration, have someone hold the horse that is familiar with the actions of succinylcholine chloride so that the animal does not fall forward on its nose. Be prepared to administer oxygen and artificial respiration.
- 7) If death occurs, a necropsy should be performed.

Adverse Effects

Succinylcholine chloride can cause muscle soreness, histamine release, malignant hyperthermia, excessive salivation, hyperkalemia, rash, and myoglobinemia/myoglobinuria. Cardiovascular effects can include bradycardia, tachycardia, hypertension, hypotension, or arrhythmias.

Reproductive/Nursing Safety

It is unknown if succinylcholine can cause fetal harm. The drug does cross the placenta in low concentrations and a newly delivered neonate may show signs of neuromuscular blockade if the mother received high doses or prolonged administration of the drug prior to delivery. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

It is not known whether this drug is excreted into milk; exercise caution when succinylcholine is administered to a nursing patient.

Overdosage/Acute Toxicity

Inadvertent overdoses, or standard doses in patients deficient in pseudocholinesterase may result in prolonged apnea. Mechanical ventilation with O₂ should be used until recovery.

Repeated or prolonged high dosages may cause patients to convert from a phase I to a phase II block.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succinylcholine and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** May increase succinylcholine's effects by causing electrolyte imbalances
- **DIGOXIN:** Succinylcholine may cause a sudden outflux of potassium from muscle cells, thus causing arrhythmias in digitalized patients
- **OPIATES:** Potential for increased incidences of bradycardia and sinus arrest
- **THIAZIDE DIURETICS:** May increase succinylcholine's effects by causing electrolyte imbalances

The following drugs/drug classes may increase or prolong neuromuscular blockade if used concurrently with succinylcholine:

- **AMINOGLYCOSIDES**
- **ANESTHETICS, INHALATION** (isoflurane, desflurane)
- **ANTIARRHYTHMICS** (quinidine, lidocaine, procainamide)
- **BETA-ADRENERGIC BLOCKERS**
- **CHLOROQUINE**
- **CLINDAMYCIN**
- **CORTICOSTEROIDS**
- **CYCLOPHOSPHAMIDE**
- **MAGNESIUM SALTS**
- **MAO INHIBITORS**
- **METOCLOPRAMIDE**
- **NEOSTIGMINE**
- **ORGANOPHOSPHATES**
- **OXYTOCIN**
- **PANCURONIUM**
- **PHENOTHIAZINES**
- **PROCAINE (IV)**
- **TERBUTALINE**
- **THIOTEPA**

Doses

- **DOGS:**
 - a) 0.07 mg/kg IV (Morgan 1988)
 - b) 0.22 mg/kg IV (Mandsager 1988)
- **CATS:**
 - a) 0.06 mg/kg IV (Morgan 1988)
 - b) 0.11 mg/kg IV (Mandsager 1988)

- **HORSES:**

See Precautions above. (**Note:** ARCI UCGFS Class 2 Drug)

- a) 0.088 mg/kg (Muir)
- b) 0.088–0.11 mg/kg IV, IM (Mandsager 1988)

- **REPTILES:**

- a) To relax an animal to allow intubation: 0.5–1 mg/kg IM. Especially helpful with turtles and crocodilians. (Lewbart 2001)

Monitoring

- Level of muscle relaxation
- Cardiac rate/rhythm
- Respiratory depressant effect

Client Information

- This drug should only be used by professionals familiar with its use

Chemistry/Synonyms

A depolarizing neuromuscular blocking agent, succinylcholine chloride occurs as an odorless, white, crystalline powder. The dihydrate form melts at 190°C and the anhydrous form at 160°C. Aqueous solutions are acidic with a pH of approximately 4. One gram is soluble in about 1 mL of water and about 350 mL of alcohol. Commercially available injections have a pH from 3–4.5.

Succinylcholine chloride may also be known as: choline chloride succinate, succinurium chloride, succinylcholine chloride, suxamethonium chloridum, suxametonklorid, suxamethonium chloride; many trade names are available.

Storage/Stability/Compatibility

Commercial injectable solutions should be stored refrigerated (2°–8°C). One manufacturer (*Anectine*®—Glaxo Wellcome) states that multiple dose vials are stable up to 2 weeks at room temperature with no significant loss of potency.

The powder forms of the drug are stable indefinitely when stored unopened at room temperature. After reconstitution with either D₅W or normal saline, they are stable for 4 weeks at 5°C or 1 week at room temperature, but because they contain no preservative, it is recommended they be used within 24 hours.

Succinylcholine chloride is physically **compatible** with all commonly used IV solutions, amikacin sulfate, cephalirin sodium, isoproterenol HCl, meperidine HCl, norepinephrine bitartrate, and scopolamine HBr. It **may not be compatible** with pentobarbital sodium and is physically **incompatible** with sodium bicarbonate and thiopental sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Succinylcholine Chloride Injection: 20 mg/mL & 50 mg/mL in 10 mL vials, amps and 5 mL *Abboject* syringes; *Anectine*® (GlaxoWellcome); *Quelicin*® (Hospira); (Rx)

Succinylcholine Chloride Powder for Infusion: 500 mg and 1 gram vials; *Anectine*® *Flo-Pak* (GlaxoWellcome); (Rx)

SUCRALFATE

(soo-kral-fate) Carafate®

GASTROPROTECTANT

Prescriber Highlights

- ▶ Locally-acting treatment for GI ulcers; may also protect somewhat against GI ulceration. Potentially could be useful for lowering serum phosphorus in renal patients.
- ▶ Contraindications: None, use with caution where decreased GI transit times may be harmful
- ▶ Adverse Effects: Unlikely; constipation possible
- ▶ Give on empty stomach if possible
- ▶ Drug Interactions

Uses/Indications

Sucralfate has been used in the treatment of oral, esophageal, gastric, and duodenal ulcers. It has also been employed to prevent drug-induced (e.g., aspirin) gastric erosions, but efficacy for this is somewhat sporadic. Sucralfate has been used in human patients with hyperphosphatemia secondary to renal failure and potentially could be useful for this in animals as well.

Pharmacology/Actions

While the exact mechanism of action of sucralfate as an antiulcer agent is not known, the drug has a local effect rather than a systemic one. After oral administration, sucralfate reacts with hydrochloric acid in the stomach to form a paste-like complex that will bind to the proteinaceous exudates that generally are found at ulcer sites. This insoluble complex forms a barrier at the site and protects the ulcer from further damage caused by pepsin, acid, or bile.

Sucralfate may have some cytoprotective effects, possibly by stimulation of prostaglandin E₂ and I₂. Sucralfate also has some antacid activity, but it is believed that this is not of clinical importance.

Sucralfate does not significantly affect gastric acid output, or trypsin or pancreatic amylase activity. It may decrease the rate of gastric emptying.

As an aluminum salt, sucralfate can bind to gastrointestinal phosphorus.

Pharmacokinetics

Animal studies have indicated that only 3–5% of an oral dose is absorbed which is excreted in the urine unchanged within 48 hours. By reacting with hydrochloric acid in the gut, the remainder of the drug is converted to sucrose sulfate which is excreted in the feces within 48 hours. The duration of action (binding to ulcer site) may persist up to 6 hours after oral dosing.

Contraindications/Precautions/Warnings

There are no known contraindications to the use of sucralfate. Because it may cause constipation, it should be used with caution in animals where decreased intestinal transit times might be deleterious.

Adverse Effects

Adverse effects are uncommon with sucralfate therapy. Constipation is the most prominent adverse effect reported in humans (2%) and dogs receiving the drug.

Reproductive/Nursing Safety

It is unknown if sucralfate crosses the placenta and whether it may definitively be used safely during pregnancy. In rats, dosages up to 38 times those used in humans caused no impaired fertility and doses up to 50 times normal caused no symptoms of teratogenicity. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

It is not known whether this drug is excreted in milk, but it is unlikely to be of concern.

Overdosage/Acute Toxicity

Overdosage is unlikely to cause any significant problems. Laboratory animals receiving up to 12 grams/kg orally demonstrated no incidence of mortality.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sucralfate and may be of significance in veterinary patients:

Sucralfate may impair the oral absorption of the following medications; separate dosing by at least 2 hours to minimize this effect:

- CIPROFLOXACIN (assume other **oral fluoroquinolones** as well)
- DICLOFENAC
- DIGOXIN
- KETOCONAZOLE
- LEVOTHYROXINE
- PENICILLAMINE
- TETRACYCLINES
- VITAMINS (fat soluble)
- WARFARIN

Doses

■ DOGS:

- a) For esophagitis: 0.5–1 gram PO three times a day. Suspensions are more therapeutic than intact tablets. (Washabau 2000)
- b) For large dogs: 1 gram PO q8h; for smaller dogs: 0.5 gram PO q8h (Zerbe and Washabau 2000)
- c) 0.5–1 gram PO 2–4 times a day; patients with severe GI blood loss give an initial loading dose of 3–6 grams and then resume lower dose. If also using an H₂ blocker, administer sucralfate 30–60 minutes later. (Hall 2000)
- d) For eliminating *Helicobacter* gastritis infections: Using triple therapy: Metronidazole 33 mg/kg once daily, amoxicillin 11 mg/kg q12h and either sucralfate (0.25–0.5 grams q8h) or omeprazole 0.66 mg/kg once daily (Hall 2000)
- e) In patients with severe hematemesis and anemia we sometimes give a loading dose of 3–6 grams initially and then decrease to 1 gram PO three to four times a day. May not always work in vomiting dogs. Suspensions may have less tendency to be vomited up in these patients. (Willard 2006d)
- f) For gastric ulcers, esophagitis: 0.5–1 gram PO per dog q8–12h (Sellon 2007b)

- g) For GI ulcers/esophagitis associated with acute renal failure: 1 gram per 30 kg body weight PO q6h (Waddell 2007a)

■ **CATS:**

- a) 0.25–0.5 grams PO q8–12h (Zerbe and Washabau 2000)
b) 0.25 gram PO q8–12h (Matz 1995)
c) For gastric ulcers, esophagitis: 0.25–0.5 grams PO per cat PO q8–12h (Sellon 2007b)

■ **FERRETS:**

- a) 75 mg/kg PO q4–6h; give 10 minutes prior to feeding (Williams 2000)

■ **HORSES:**

- a) For adjunctive treatment for preventing stress-induced ulcers in foals: 10–20 mg/kg PO q6–8h (Sanchez 2004b)
b) For treating equine gastric ulcer syndrome: 20–40 mg/kg PO q8h (Sanchez 2004b), (Nadeau and Andrews 2003)

■ **REPTILES:**

- a) For GI irritation in most species: 500–1,000 mg/kg PO q6–8h (Gauvin 1993)

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.

Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; clinical signs may reoccur if dosages are missed
■ Unless otherwise instructed, give this medication to animal having an empty stomach (1 hour before feeding or 2 hours after) and at bedtime

Chemistry/Synonyms

A basic, aluminum complex of sucrose sulfate, sucralfate occurs as a white, amorphous powder. It is practically insoluble in alcohol or water.

Sucralfate is structurally related to heparin, but does not possess any appreciable anticoagulant activity. It is also structurally related to sucrose, but is not utilized as a sugar by the body.

Sucralfate is also known as aluminum sucrose sulfate, basic and *Carafate*®.

Storage/Stability

Store sucralfate tablets in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sucralfate Tablets: 1 gram (scored); *Carafate*® (Axcen Sandipharma); generic; (Rx)

Sucralfate Suspension: 1 g/10 mL in 10 mL unit dose cups & 415 mL; *Carafate*® (Axcen Scandipharma); generic (Precision Dose); (Rx)

SUFENTANIL CITRATE

(*soo-fen-ta-nil*) Sufenta®

OPIATE AGONIST

Prescriber Highlights

- Injectable, extremely potent opiate that may be useful for adjunctive anesthesia or epidural analgesia
- Marginal veterinary experience & little published data available to draw conclusions on appropriate usage in veterinary species
- Dose-related respiratory & CNS depression most likely adverse effects
- Class-II controlled substance; expensive when compared to fentanyl

Uses/Indications

An opioid analgesic, sufentanil may be useful as an anesthesia adjunct or as an epidural analgesic. In humans, it has been used as the primary anesthetic in intubated patients with assisted ventilation, and as a post-operative analgesic.

Pharmacology/Actions

Sufentanil is a potent *mu* opioid with the expected sedative, analgesic, and anesthetic properties. When comparing analgesic potencies, 0.01–0.04 mg of sufentanil is equivalent to 0.4–0.8 mg of alfentanil, 0.1–0.2 mg of fentanyl, and approximately 10 mg of morphine, when all are injected IM. Like fentanyl, sufentanil appears to have less circulatory effects than does morphine. Sufentanil has a rapid onset of action (1–3 minutes) and a faster recovery time than fentanyl.

Pharmacokinetics

No information on the pharmacokinetics of sufentanil in domestic animals was located. In humans, the drug has rapid onset of action (1–3 minutes) after intravenous injection. The drug is highly lipid soluble and has volume of distribution in the central compartment of 0.1 L/kg. Approximately 93% is bound to plasma proteins; plasma concentrations rapidly decline due to redistribution. Terminal elimination half-life is about 2.5 hours. Plasma clearance has been reported to be 11.8 mL/min/kg. Sufentanil is metabolized primarily in the liver and small intestine via O-demethylation and N-dealkylation. The parent drug and these metabolites are excreted primarily in the urine. While the manufacturer states to use with caution in patients with impaired renal or hepatic function, limited pharmacokinetic studies in these patients, rarely showed any drug accumulation.

Contraindications/Precautions/Warnings

Sufentanil is contraindicated in patients hypersensitive to it or other opioids. It should be used with caution in debilitated or geriatric patients and those with severely diminished renal or hepatic function.

Because of the drug's potency and potential for significant adverse effects, it should only be used in situations where patient vital signs can be continuously monitored. Initial dosage reduction may be required in geriatric or debilitated patients, particularly those with diminished cardiopulmonary function.

Adverse Effects

Adverse effects are generally dose related and consistent with other opiate agonists. Respiratory depression and/or CNS depression are most likely to be encountered.

In humans, bradycardia that is usually responsive to anticholinergic agents can occur. Dose-related skeletal muscle rigidity is not uncommon, and neuromuscular blockers are routinely used. Sufentanil has rarely been associated with asystole, hypercarbia and hypersensitivity reactions.

Respiratory or CNS depression may be exacerbated if sufentanil is given with other drugs that can cause those effects.

Reproductive/Nursing Safety

In humans, the FDA categorizes sufentanil as a category **C** drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) While sufentanil is indicated for epidural use (mixed with bupivacaine \pm epinephrine) in women for labor/delivery, it should not be administered systemically to a mother close to giving birth as offspring may show behavioral alterations (hypotonia, depression) associated with opioids.

The effects of sufentanil on lactation or its safety for nursing offspring is not well-defined, but sufentanil milk levels approximate those found in serum. This coupled with its low oral bioavailability, make it unlikely to cause significant effects in nursing offspring.

Overdosage/Acute Toxicity

In dogs, the LD₅₀ of intravenous sufentanil is 10.1–19.5 mg/kg. Intravenous severe overdoses may cause apnea, circulatory collapse, pulmonary edema, seizures, cardiac arrest and death. Treatment is a combination of supportive therapy and administration of an opiate antagonist such as naloxone. Although sufentanil has a fairly rapid half-life, multiple doses of naloxone may be necessary. Because of the drug's potency, the use of a tuberculin syringe to measure dosages less than 1 mL, with a dosage calculation and measurement double-check system is recommended.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sufentanil and may be of significance in veterinary patients:

- **BETA-ADRENERGIC BLOCKERS:** May increase bradycardia and hypotension
- **CALCIUM-CHANNEL BLOCKERS:** May increase bradycardia and hypotension
- **CNS DEPRESSANTS, OTHER:** Additive effects can occur if sufentanil is used concurrently with other drugs that can depress CNS or respiratory function (e.g., **barbiturates**, etc.)
- **NITROUS OXIDE:** Can cause cardiovascular depression if used with high dose sufentanil

Laboratory Considerations

- Because opiates can increase biliary tract pressure and raise serum **amylase** and **lipase** values, these values may be unreliable for 24 hours after sufentanil is administered.

Doses

(**NOTE:** In very obese patients, figure dosages based upon lean body weight.)

■ DOGS:

- a) As a pre-med: 3 mcg/kg IV. As a combination for induction: Sufentanil 3 mcg/kg IV first, then diazepam or midazolam 0.2–0.5 mg IV. (Banyard 2004)
- b) For epidural analgesia: 0.7–1 mcg/kg diluted to a volume of 0.26 mL/kg with sterile saline. Onset of action in 10–15 minutes; duration 1–4 hours. (Otero 2006b)
- c) Acute pain relief in an emergency: 0.75–2 mcg/kg IV; constant rate infusion of 1–2 mcg/kg/hour. (Otero 2006a)
- d) For surgical pain: 5 mcg/kg IV prior to a CRI. Duration of effect: 2–6 hours. CRI (post-operative) of 0.1 mcg/kg/hour. (Ogilvie 2004)

■ CATS:

- a) Acute pain relief in an emergency: 0.1–0.5 mcg/kg IV; constant rate infusion of 0.5–1 mcg/kg/hour. (Otero 2006a)

Monitoring

- Anesthetic and/or analgesic efficacy
- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia

Client Information

- Sufentanil is a very potent opiate that should only be used by professionals in a setting where adequate patient monitoring is available.

Chemistry/Synonyms

A phenylpiperidine derivative opioid related to fentanyl, sufentanil citrate occurs as a white or almost white powder that is soluble in water, sparingly soluble in alcohol, acetone, or chloroform. The commercially available injection has a pH (adjusted with citric acid) of 3.5–6.

Sufentanil citrate may also be known as: R-33800, sufentanili citras, fentathienel citrate, sufentanil citrate, sulfentanil citrate, *Fastfen*®, *Fentaientel*® and *Sufenta*®.

Storage/Stability/Compatibility

Unless otherwise labeled, sufentanil injection should be protected from light at room temperature. Sufentanil citrate is hydrolyzed in acidic solutions.

Sufentanil citrate is reportedly **compatible** with D5W and bupivacaine. For Y-site injection it is **compatible** with solutions containing: atropine, dexamethasone sodium phosphate, diazepam, diphenhydramine, etomidate, metoclopramide, midazolam, phenobarbital, and propofol. It is **incompatible** with lorazepam, phenytoin and thiopental.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Sufentanil Citrate Injection: 50 mcg/mL (as base) in 1 mL, 2 mL and 5 mL amps; *Sufenta*® (preservative free) (Taylor); generic (with preservatives); (Rx, C-II).

SULFACHLORPYRIDAZINE SODIUM

(sul-fa-klor-pye-*rid*-a-zeen) Vetisulid®

SULFONAMIDE ANTIBACTERIAL

Prescriber Highlights

- ▶ **Contraindications:** Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
- ▶ **Caution:** Diminished renal or hepatic function, or urinary obstruction
- ▶ **Adverse Effects:** Can precipitate in the urine (especially with high dosages for prolonged periods, acidic urine or highly concentrated urine); DOGS: Keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting, & non-septic polyarthritis possible
- ▶ **Potentially teratogenic;** weigh risk vs. benefit
- ▶ **Too-rapid IV injection** may cause muscle weakness, blindness, ataxia, & collapse; SC or IM injection may cause tissue irritation

Uses/Indications

Sulfachlorpyridazine is indicated for the treatment of diarrhea caused or complicated by *E. coli* in calves less than one month of age or colibacillosis in swine. It is also used parenterally as a general-purpose sulfonamide in adult cattle and other species.

Pharmacology/Actions

Sulfonamides are usually bacteriostatic agents when used alone. They are thought to prevent bacterial replication by competing with para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfas.

Microorganisms that are usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *C. perfringens*, and many strains of *Nocardia*. Sulfas have *in vitro* activity against some gram-negative species, including some strains of *Shigella*, *Salmonella*, *E. coli*, *Klebsiella*, *Enterobacter*, *Pasturella*, and *Proteus*. Sulfas also have activity against some rickettsia and protozoa (*Toxoplasma*, *Coccidia*). Unfortunately, resistance to sulfas is a progressing phenomenon and many strains of bacteria that were once susceptible to this class of antibacterial are now resistant. The sulfas are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

Pharmacokinetics

Very limited information is available on the specific pharmacokinetics for this agent. In general, sulfonamides are readily absorbed from the GI tract of non-ruminants, but absorption can vary depending on the drug, species, disease process, etc. Food delays the rate, but usually not the extent of absorption. Peak levels occur within 1–2 hours in non-ruminant (and young pre-ruminant) animals. Adult ruminants may have significant delays before the drug is absorbed orally.

Sulfas are well distributed throughout the body and some reach significant levels in the CSF. Levels of the drugs tend to be highest in liver, kidney, and lung, and lower in muscle and bone. The sulfas can be highly bound to serum proteins, but the extent of binding

is species and drug dependent. When bound to proteins the sulfa is not active.

Sulfonamides are both renally excreted and metabolized. Renal excretion of unchanged drug occurs via both tubular secretion and glomerular filtration. Protein bound drug is not filtered by the glomeruli. Metabolism is performed principally in the liver, but extra-hepatic metabolism is also involved. Mechanisms of metabolism are usually acetylation and glucuronidation. The acetylated metabolites may be less soluble and crystallization in the urine can occur with some sulfonamides, particularly at lower pH. The serum half-life of sulfachlorpyridazine is approximately 1.2 hours in cattle.

Contraindications/Precautions/Warnings

Sulfonamides are contraindicated in patients hypersensitive to them, thiazides, or sulfonylurea agents. They are also considered contraindicated in patients with severe renal or hepatic impairment and should be used with caution in patients with diminished renal or hepatic function, or urinary obstruction.

Oral sulfonamides can depress the normal cellulytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Adverse Effects

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH's. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but it also decreases the amount available for tubular reabsorption. Crystalluria can usually be avoided with most of the commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

Too rapid intravenous injection of the sulfas can cause muscle weakness, blindness, ataxia, and collapse.

In dogs, keratoconjunctivitis sicca has been reported with sulfonamide therapy. In addition, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported in dogs.

Oral sulfonamides can depress the normal cellulytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

Reproductive/Nursing Safety

Sulfas cross the placenta and may reach fetal levels of 50% or greater those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk. Safe use during lactation cannot be assumed; use with caution.

Overdosage/Acute Toxicity

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfachlorpyridazine and may be of significance in veterinary patients:

- **ANTACIDS:** May decrease the oral bioavailability of sulfonamides if administered concurrently

Laboratory Considerations

- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Doses

■ CATTLE:

In calves for labeled indications: 33–49.5 mg/kg PO, or IV twice daily for 1–5 days; suggest initiating therapy with intravenous preparation and then changing to oral if possible (Package insert; *Vetisulid*®—Fort Dodge)

■ SWINE:

For labeled indications: 44–77 mg/kg PO per day (divide dose and give twice daily if treating individual animals) for 1–5 days (Package insert; *Vetisulid*®—Fort Dodge)

■ BIRDS:

For enteric bacterial infections:

- Using the oral powder: Mix 1/4 teaspoonful per liter of water and use as only supply of drinking water for 5–10 days. May be effective for many *E. coli* enteric infections. (Clubb 1986)
- Using the oral powder: Mix 3/4 teaspoonsful per 2 quarts of water. Fairly effective for enteric infections, particularly *E. coli*. Reserved for clients who are unable to give other medications by mouth or parenterally. (McDonald 1989)
- For pigeons: 1200 mg per gallon of drinking water. Very effective for *E. coli* and it is a good coccidiostat. (Harlin 2006)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- To help reduce the possibility of crystalluria occurring, animals should have free access to water; avoid dehydration.

Chemistry/Synonyms

Sulfachlorpyridazine sodium is listed as a short to intermediate-acting, low lipid soluble sulfonamide antibacterial. It is reportedly very soluble in urine at usual pH's.

Sulfachlorpyridazine may also be known as cluricol, sulphachlorpyridazine, or *Vetisulid*®.

Storage/Stability/Compatibility

The injection should be stored at room temperature and protected from light; avoid freezing. The oral suspension should be stored at room temperature; avoid freezing. The oral boluses and powder should be stored at room temperature; avoid excessive heat (above 40°C/104°F).

No information was located regarding the compatibility of sulfachlorpyridazine with other fluids or agents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sulfachlorpyridazine Sodium Oral powder: 54 grams per bottle; *Vetisulid*® Powder (Fort Dodge); (OTC) Indicated for use in calves under one month of age and swine. Slaughter withdrawal (at labeled doses) = 7 days for cattle and 4 days for swine.

Sulfachlorpyridazine Sodium Oral Suspension: 50 mg/mL in 180 mL bottles; *Vetisulid*® Oral Suspension (Fort Dodge); (OTC). Approved for use in swine. Slaughter withdrawal (at labeled doses) = 4 days for swine.

HUMAN-LABELED PRODUCTS: None

Sulfadiazine/Pyrimethamine — See Pyrimethamine/Sulfadiazine

SULFADIAZINE/TRIMETHOPRIM SULFAMETHOXAZOLE/ TRIMETHOPRIM

(sul-fa-dye-a-zeen; sul-fa-meth-ox-a-zole/trye-meth-ohe-prim) Co-trimoxazole, Tribissen®, Bactrim®, Septra®

POTENTIATED SULFONAMIDE ANTIMICROBIAL

Note: In the practice of veterinary medicine in the USA, two separate combinations with trimethoprim are used clinically. There are trimethoprim/sulfadiazine products approved for use in dogs, cats, and horses in both parenteral and oral dosage forms. Many veterinarians also use the human approved, trimethoprim/sulfamethoxazole oral products. In Canada, sulfadoxine is available in combination with trimethoprim for veterinary use.

Prescriber Highlights

- Potentiated sulfonamide antimicrobial agent
- **Contraindications:** Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
- **Caution:** Diminished renal or hepatic function, or urinary obstruction or urolithiasis
- **Adverse Effects:** **DOGS:** Keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemias, agranulocytosis, idiosyncratic hepatic necrosis in dogs. **CATS:** Anorexia, crystalluria, hematuria, leukopenias & anemias. **HORSES:** Transient pruritic (after IV injection). Oral: diarrhea, hypersensitivity reactions & hematologic effects (anemias, thrombocytopenia, or leukopenias)
- Local injection effects possible (check label for product recommendation for injection technique)
- Potentially teratogenic, weigh risk vs. benefit

Uses/Indications

Although only approved for use in dogs and horses, trimethoprim/sulfadiazine etc. is used in many species to treat infections caused by susceptible organisms. See Dosage section for more information.

Pharmacology/Actions

Alone, sulfonamides are bacteriostatic agents and trimethoprim is bactericidal, but when used in combination, the potentiated sulfas are bactericidal. Potentiated sulfas sequentially inhibit enzymes in the folic acid pathway, inhibiting bacterial thymidine synthesis. The sulfonamide blocks the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA), and trimethoprim blocks the

conversion of DFA to tetrahydrofolic acid by inhibiting dihydrofolate reductase.

The *in vitro* optimal ratio for most susceptible bacteria is approximately 1:20 (trimethoprim:sulfa), but synergistic activity can reportedly occur with ratios of 1:1–1:40. The serum concentration of the trimethoprim component is considered more important than the sulfa concentration. For most susceptible bacteria, the MIC's for TMP are generally above 0.5 mcg/mL.

The potentiated sulfas have a fairly broad spectrum of activity. Gram-positive bacteria that are generally susceptible include most streptococci, many strains of staphylococcus, and *Nocardia*. In horses, approximately 30% of strains tested of *Streptococcus zooepidemicus* are resistant to TMP/Sulfa. Many gram-negative organisms of the family Enterobacteriaceae are susceptible to the potentiated sulfas, but not *Pseudomonas aeruginosa*. Some protozoa (*Pneumocystis carinii*, Coccidia, and Toxoplasma) are also inhibited by the combination. Potentiated sulfas reportedly have little activity against most anaerobes, but opinions on this vary.

Resistance will develop more slowly to the combination of drugs than to either one alone. In gram-negative organisms, resistance is usually plasmid-mediated.

Pharmacokinetics

Trimethoprim/sulfa is well absorbed after oral administration, with peak levels occurring about 1–4 hours after dosing; the drug is more slowly absorbed after subcutaneous absorption, however. In ruminants, trimethoprim is apparently trapped in the ruminoreticulum after oral administration and undergoes some degradation.

Trimethoprim/sulfa is well distributed in the body. When meninges are inflamed, the drugs enter the CSF in levels of about 50% those found in the serum. Both drugs cross the placenta and are distributed into milk. The volume of distribution for trimethoprim in various species are: 1.49 L/kg (dogs); 0.59–1.51 L/kg (horses). The volume of distribution for sulfadiazine in dogs is 1.02 L/kg.

Trimethoprim/sulfa is both renally excreted unchanged via glomerular filtration and tubular secretion and metabolized by the liver. The sulfas are primarily acetylated and conjugated with glucuronic acid and trimethoprim is metabolized to oxide and hydroxylated metabolites. Trimethoprim may be more extensively metabolized in the liver in adult ruminants, than in other species. The serum elimination half-lives for trimethoprim in various species is: 2.5 hours (dogs), 1.91–3 hours (horses), 1.5 hours (cattle). The serum elimination half-lives for sulfadiazine in various species is: 9.84 hours (dogs), 2.71 hours (horses), and 2.5 hours (cattle). While trimethoprim is rapidly eliminated from the serum, the drug may persist for a longer period of time in tissues.

Because of the number of variables involved, it is extremely difficult to apply pharmacokinetic values in making dosage recommendations with these combinations. Each drug (trimethoprim and the sulfa) has different pharmacokinetic parameters (absorption, distribution, elimination) in each species. Since different organisms have different MIC values and the optimal ratio of trimethoprim to sulfa differs from organism to organism, this problem is exacerbated.

There is considerable controversy regarding the frequency of administration of these combinations. The veterinary product, trimethoprim/sulfadiazine is labeled for once daily administration in dogs and horses, but many clinicians believe that the drug is more efficacious if given twice daily, regardless of which sulfa is used.

Contraindications/Precautions/Warnings

The manufacturer states that trimethoprim/sulfadiazine should not be used in dogs or horses showing marked liver parenchymal damage, blood dyscrasias, or those with a history of sulfonamide sensitivity. It is not for use in horses (or approved for other animals) intended for food.

This combination should be used with caution in patients with pre-existing hepatic disease.

Because of its potential for crystallization in the urine, it may be wise to avoid the use of sulfadiazine in dogs known to have uroliths, at increased risk for developing uroliths or known to have highly concentrated or acidic urine.

Adverse Effects

Adverse effects noted in dogs include: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria and cholestasis. Potentiated sulfonamides may cause hypothyroidism in dogs, particularly with extended therapy. Acute hypersensitivity reactions manifesting as Type I (anaphylaxis) or Type III reaction (serum sickness) can be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers may possibly be more susceptible to this effect than other breeds. Other hematologic effects (anemias, agranulocytosis) are possible, but fairly rare. TMP/Sulfa has rarely been noted to cause an idiosyncratic, moderate to massive hepatic necrosis. TMP/Sulfa may be a risk factor for developing acute pancreatitis, but cause and effect have not been definitively shown.

Adverse effects noted in cats may include anorexia, leukopenias and anemias.

In horses, transient pruritus has been noted after intravenous injection. Oral therapy has resulted in diarrhea in some horses. Previous administration of potentiated sulfas has been implicated in increasing the mortality rate of associated with severe diarrhea. If the 48% injectable product is injected IM, SC, or extravasates after IV administration, swelling, pain and minor tissue damage may result. Hypersensitivity reactions and hematologic effects (anemias, thrombocytopenia, or leukopenias) may also be seen; long-term therapy should include periodic hematologic monitoring.

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic urine or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction.

Reproductive/Nursing Safety

Safety of trimethoprim/sulfa has not been clearly established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported. Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Use TMP/sulfa products in nursing animals with caution. TMP-SMZ is not recommended for human use in the nursing period as sulfonamides are excreted in milk and may cause kernicterus. Premature infants and infants with hyperbilirubinemia or G-6-PD deficiency are also at risk for adverse effects.

Overdosage/Acute Toxicity

Manifestations of an acute overdosage can include clinical signs of GI distress (nausea, vomiting, diarrhea), CNS toxicity (depression, headache, and confusion), facial swelling, bone marrow depression and increases in serum aminotransferases. Oral overdoses can be treated by emptying the stomach, (following usual protocols), and initiating symptomatic and supportive therapy. Acidification of the urine may increase the renal elimination of trimethoprim, but could also cause sulfonamide crystalluria, particularly with sulfadiazine containing products. Complete blood counts (and other laboratory parameters) should be monitored as necessary. Bone marrow suppression associated with chronic overdoses may be treated with folinic acid (leucovorin) if severe. Peritoneal dialysis is not effective in removing TMP or sulfas from the circulation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trimethoprim/sulfa and may be of significance in veterinary patients:

- **AMANTADINE:** A human patient developed toxic delirium when receiving amantadine with TMP/sulfa
- **ANTACIDS:** May decrease the bioavailability of sulfonamides if administered concurrently
- **CYCLOSPORINE:** TMP/sulfa may increase the risk of nephrotoxicity
- **DIGOXIN:** TMP/sulfa may increase digoxin levels
- **DIURETICS, THIAZIDE:** May increase risk for thrombocytopenia
- **HYPOGLYCEMIC AGENTS, ORAL:** TMP/sulfa may potentiate effects
- **METHOTREXATE:** TMP/sulfa may displace from plasma proteins and increase risk for toxic effects; it can also interfere with MTX assays (competitive protein binding technique)
- **PHENYTOIN:** TMP/sulfa may increase half-life
- **TRICYCLIC ANTIDEPRESSANTS:** TMP/sulfa may decrease efficacy
- **WARFARIN:** TMP/sulfa may prolong INR/PT

Laboratory Considerations

- When using the Jaffe alkaline picrate reaction assay for **creatinine** determination, trimethoprim/sulfa may cause an overestimation of approximately 10%.
- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Doses

Note: There is significant controversy regarding the frequency of dosing these drugs. See the pharmacokinetic section above for more information. Unless otherwise noted, doses are for combined amounts of trimethoprim/sulfa.

■ DOGS:

For susceptible infections:

- a) For UTI, pyoderma, soft tissue infections: 30 mg/kg PO q24h (not soft tissue infections) or 15 mg/kg PO q12h for 14 days.

For chronic pyoderma, acanthamebiasis: 30 mg/kg PO q12h for 21–42 days.

For systemic infections; bacteremia: 30–45 mg/kg PO q12h for 3–5 days. (Greene, Hartmann et al. 2006)

- b) For bacterial UTI: 30 mg/kg q12h PO (Bartges 2007)

- c) For protozoal diseases:

For toxoplasmosis: 15 mg/kg, PO q12h for 28 days.

For Neospora: 15 mg/kg, PO q12h for 4 weeks. Used concurrently with clindamycin (10 mg/kg q12h for 4 weeks) or pyrimethamine (1 mg/kg PO once daily for 4 weeks).

For *Hepatazoon canis*: 15 mg/kg, PO q12h for 2–4 weeks. Used concurrently with clindamycin (10 mg/kg PO q8h for 2–4 weeks) and pyrimethamine (0.25 mg/kg PO once daily for 2–4 weeks) (Lappin 2000)

- d) For coccidiosis: 30 mg/kg PO once daily for 10 days (Matz 1995)
- e) For pneumocystosis (*Pneumocystis carinii*): 15 mg/kg PO q8h or 30 mg/kg PO q12h, both for 3 weeks. May be given with cimetidine and levamisole as potential immune stimulants. (Hawkins 2000)
- f) For *Hepatazoon americanum*: TMP/sulfa (15 mg/kg PO q12h), pyrimethamine (0.25 mg/kg PO q24h), and clindamycin (10 mg/kg q8h). Once remission attained decoquinatate (see monograph) can maintain. (Baneth 2007)
- g) For *Hepatazoon americanum*: TMP/sulfa (15 mg/kg PO q12h for 14 days), pyrimethamine (0.25 mg/kg PO q24h for 14 days), and clindamycin (10 mg/kg q8h for 14 days). Once remission attained decoquinatate (see monograph) can maintain.

For neosporosis: pyrimethamine (1 mg/kg PO daily) with TMP/sulfa (15–30 mg/kg PO twice daily. (Blagburn 2005a)

■ CATS:

For susceptible infections:

- a) For UTI: 30 mg/kg PO q24h for 7–14 days.
For UTI, soft tissue infections: 15 mg/kg PO q12h for 7–14 days. (Greene, Hartmann et al. 2006)
- b) 30 mg/kg q12h (if treating Nocardia, double dose) (Ford and Aronson 1985)
- c) For toxoplasmosis: 15 mg/kg PO q12h for 28 days (Lappin 2000)
- d) For bacterial UTI: 30 mg/kg q12h PO (Bartges 2007)

■ FERRETS:

For susceptible infections:

- a) 30 mg/kg PO twice daily (Williams 2000)
- b) For coccidiosis: 30 mg/kg PO once daily for 14 days. (Johnson 2006c)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 15–30 mg/kg, PO q12–24h; 30–48 mg/kg SC q12h. Sulfadiazine has a very short half-life (approx. 1 hour) in rabbits. (Ivey and Morrissey 2000)
- b) Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 15–30 mg/kg PO q12h; or 30 mg/kg IM q12h (Adamcak and Otten 2000)
- c) Chinchillas: 30 mg/kg PO, SC or IM q12h (Hayes 2000)

■ CATTLE:

For susceptible infections:

- a) 44 mg/kg once daily IM or IV using 48% suspension (Upson 1988)
- b) 25 mg/kg, IV or IM q24h (Burrows 1980)
- c) Calves: 48 mg/kg IV or IM q24h (Baggot 1983)

■ HORSES:

For susceptible infections:

- a) For respiratory tract infections: 15–30 mg/kg PO q12h. Give 30 minutes prior to feeding hay (grain is OK) (Foreman 1999)

- b) Foals: 15 mg/kg IV q12h; 30 mg/kg PO q12h (Brumbaugh 1999)
- c) 22 mg/kg IV q24h or 30 mg/kg, PO q24h (Upson 1988)
- d) 30 mg/kg PO once daily or 21.3 mg/kg IV once daily (Package inserts; *Tribriksen*®—Coopers)
- e) Foals: 15 mg/kg PO or IV twice daily (Furr 1999)
- f) For EPM: Sulfadiazine 20 mg/kg (either alone or as a potentiated sulfa) PO once or twice a day with Pyrimethamine (1 mg/kg PO once a day) for 90–120 days (or longer). Monitor: CBC's (Moore 1999)

■ SWINE:

For susceptible infections:

- a) 48 mg/kg, IM q24h (Baggot 1983)

■ BIRDS:

For susceptible infections:

- a) Using TMP/SMX oral suspension (240 mg/5 mL): 2 mL/kg PO twice daily. Good for many gram-positive and negative enteric and respiratory infections, particularly in hand-fed babies. May cause emesis in Macaws. (McDonald 1989)
- b) For respiratory and enteric infections in psittacines using the 24% injectable suspension: 0.22 mL/kg IM once to twice daily.
For coccidiosis in toucans and mynahs using TMP/SMX oral suspension (240 mg/5 mL): 2.2 mL/kg once daily for 5 days. May be added to feed.
For respiratory and enteric infections in hand-fed baby psittacines using TMP/SMX oral suspension (240 mg/5 mL): 0.22 mL/30 grams twice daily to three times daily for 5–7 days. (Clubb 1986)
- c) Using oral suspension: 50–100 mg/kg (of combined product) PO q12h (Hoeffer 1995)
- d) Ratites: For *Toxoplasma gondii*: 30–50 mg/kg IM twice daily (Jenson 1998)

■ REPTILES:

For susceptible infections:

- a) For most species: 30 mg/kg IM (upper part of body) once daily for 2 treatments, then every other day for 5–12 treatments. May be useful for enteric infections. (Gauvin 1993)
- b) For all species: 30 mg/kg IM, first two doses 24 hours apart and then every other day (Jacobson 1999)
- c) 15–25 mg/kg/day IM for 7–14 days (Lewbart 2001)

Monitoring

- Clinical efficacy
- Adverse effects; with chronic therapy, periodic complete blood counts should be considered
- Thyroid function tests should be considered (baseline and ongoing) particularly in dogs receiving long-term treatment

Client Information

- If using oral suspension, shake well before using; does not need to be refrigerated
- Animals must be allowed free access to water and must not become dehydrated while on therapy
- If dogs eyes are dry or become irritated contact veterinarian

Chemistry/Synonyms

Trimethoprim occurs as odorless, bitter-tasting, white to cream-colored crystals or crystalline powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfamethoxazole occurs as a practically odorless, white to off-white, crystalline powder. Approximately 0.29 mg are soluble in 1 mL of water and 20 mg are soluble in 1 mL of alcohol.

In combination, these products may be known as: Co-trimoxazole, SMX-TMP, TMP-SMX, trimethoprim-sulfamethoxazole, sulfamethoxazole-trimethoprim, sulfadiazine-trimethoprim, trimethoprim-sulfadiazine, TMP-SDZ, SDZ-TMP, Co-trimazine or by their various trade names.

Storage/Stability

Unless otherwise instructed by the manufacturer, trimethoprim/sulfadiazine and co-trimoxazole products should be stored at room temperature (15–30°C) in tight containers.

Dosage Forms/Regulatory Status/Withdrawal Times

VETERINARY-LABELED PRODUCTS:

Trimethoprim (TMP)/Sulfadiazine (SDZ) Oral Paste: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine. Available in 37.5 gram (total weight) syringes; *Tribriksen*® 400 Oral Paste (Schering-Plough); (Rx). Approved for use in horses not intended for food.

Trimethoprim/Sulfadiazine Sterile Injection: 48% in 100 mL vials: *Di-Biotic*® 48% (Phoenix Pharmaceutical), *Tribriksen*® 48% Injection (Schering-Plough); (Rx) Approved for use in horses not intended for food.

Trimethoprim/Sulfadiazine Powder: 67 mg trimethoprim and 333 mg sulfadiazine per gram: *Tucoprim*® Powder (Pharmacia & Upjohn) in 200 g & 400 g bottles and 2000 g pails, *Uniprim*® Powder (Macleod) in 37.5 g and 1,125 g packets, 200 g jar, and 12 kg box; (Rx). Approved for use in horses not intended for food.

In Canada, trimethoprim and sulfadoxine are available for use in cattle and swine (*Trivetrim*®—Wellcome; *Borgal*®—Hoechst). Slaughter withdrawal = 10 days; milk withdrawal = 96 hours.

HUMAN-LABELED PRODUCTS:

Trimethoprim (alone) Tablets: 100 mg and 200 mg; *Proloprim*® (Glaxo Wellcome); *Trimipex*® (Roche); generic; (Rx)

Trimethoprim 80 mg and Sulfamethoxazole 400 mg Tablets; Trimethoprim 160 mg and Sulfamethoxazole 800 mg Tablets: *Bactrim*®, *Bactrim-DS*® (Roche); *Septra*®, *Septra*® DS, (Glaxo Wellcome); generic; (Rx)

Trimethoprim 8 mg/mL and Sulfamethoxazole 40 mg/mL oral suspension in 20 mL, 100 mL, 150 mL, 200 mL, 473 mL, and 480 mL; *Septra*® (GlaxoWellcome); *Cotrim*® *Pediatric* (Lemmon), *Sulfatrim*®, (various); generic; (Rx)

Trimethoprim 16 mg/5 mL (3.2 mg/mL) and Sulfamethoxazole 80 mg/5 mL (16 mg/mL) for injection in 5 mL Carpuject; 80 mg/5 mL (16 mg/mL) trimethoprim and 400 mg/5 mL (80 mg/mL) sulfamethoxazole in 10 mL, 20 mL, 30 mL multi-dose vials and 5 mL vials; *Bactrim*® IV (Roche); *Septra*® IV (Monarch); generic; (Rx)

SULFADIMETHOXINE

(sul-fa-dye-meth-ox-een) Albon®

SULFONAMIDE ANTIMICROBIAL

Prescriber Highlights

- ▶ Sulfonamide antimicrobial agent
- ▶ **Contraindications:** Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
- ▶ **Caution:** Diminished renal or hepatic function, or urinary obstruction.
- ▶ **Adverse Effects:** Can precipitate in the urine (esp. with high dosages for prolonged periods, acidic urine or highly concentrated urine). **DOGS:** Keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting & nonseptic polyarthritis possible
- ▶ Potentially teratogenic; weigh risk vs. benefit

Uses/Indications

Sulfadimethoxine injection and tablets are approved for use in dogs and cats for respiratory, genitourinary, enteric and soft tissue infections caused by susceptible organisms. Sulfadimethoxine is used in the treatment of coccidiosis in dogs although not approved for this indication.

In horses, sulfadimethoxine injection is approved for the treatment of respiratory infections caused by *Streptococcus equi*.

In cattle, the drug is approved for treating shipping fever complex, calf diphtheria, bacterial pneumonia and foot rot caused by susceptible organisms.

In poultry, sulfadimethoxine is added to drinking water to treat coccidiosis, fowl cholera, and infectious coryza.

Pharmacology/Actions

Sulfonamides are usually bacteriostatic agents when used alone. They are thought to prevent bacterial replication by competing with para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfas.

Microorganisms that are usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *C. perfringens*, and many strains of *Nocardia*. Sulfas also have *in vitro* activity against some gram-negative species, including some strains of *Shigella*, *Salmonella*, *E. coli*, *Klebsiella*, *Enterobacter*, *Pasturella*, and *Proteus*. Sulfas have activity against some rickettsia and protozoa (*Toxoplasma*, *Coccidia*). Unfortunately, resistance to sulfas is a progressing phenomenon and many strains of bacteria that were once susceptible to this class of antibacterial are now resistant. The sulfas are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

Pharmacokinetics

In dogs, cats, swine, and sheep, sulfadimethoxine is reportedly readily absorbed and well distributed. Relative volumes of distribution range from 0.17 L/kg in sheep to 0.35 L/kg in cattle and horses. The drug is highly protein bound.

In most species, sulfadimethoxine is acetylated in the liver to acetylsulfadimethoxine and excreted unchanged in the liver. In dogs, the drug is not appreciably hepatically metabolized and renal excretion is the basis for the majority of elimination of the drug. Sulfadimethoxine's long elimination half-lives are a result of its appreciable reabsorption in the renal tubules. Serum half-lives reported in various species are: swine 14 hours; sheep 15 hours; horses 11.3 hours.

Contraindications/Precautions/Warnings

Sulfonamides are contraindicated in patients hypersensitive to them, thiazides, or sulfonylurea agents. They are also considered contraindicated in patients with severe renal or hepatic impairment and should be used with caution in patients with diminished renal or hepatic function, or urinary obstruction.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Adverse Effects

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic urine or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH's. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but it also decreases the amount available for tubular reabsorption. Crystalluria can usually be avoided with most of the commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

Too rapid intravenous injection of the sulfas can cause muscle weakness, blindness, ataxia, and collapse.

In dogs, keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported with sulfonamides.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

Reproductive/Nursing Safety

Sulfas cross the placenta and may reach fetal levels of 50% or greater of those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk.

Overdosage/Acute Toxicity

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfonamides and may be of significance in veterinary patients:

- **ANTACIDS:** May decrease the oral bioavailability of sulfonamides if administered concurrently

Laboratory Considerations

- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

Doses■ **DOGS:**

For susceptible infections:

- 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
- 100 mg/kg PO, IV or IM once daily (Upson 1988)
- 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; *Albon*®—Roche)

For coccidiosis:

- 55 mg/kg PO initially on the first day of therapy, then 27.5 mg/kg PO once daily for 9 days (Matz 1995)
- 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007c)
- During the infant period (2–6 weeks): 50 mg/kg PO on the first day followed by a daily dose of 25 mg/kg PO until symptoms regress (Macintire 2004)

■ **CATS:**

For susceptible infections:

- 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
- 100 mg/kg PO, IV or IM once daily (Upson 1988)
- 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; *Albon*®—Roche)

For coccidiosis:

- 50 mg/kg once daily for the first day, then 25 mg/kg once daily for 14–20 days. Sulfas are coccidiostatic. It is important that supportive care, including fluids and good nutrition be maintained during therapy. (Cornelius and Roberson 1986)
- 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007c)

■ **FERRETS:**

For susceptible infections:

- 25 mg/kg PO, SC or IM once daily (Williams 2000)
- For coccidiosis: 25 mg/kg PO once daily for 14 days. (Johnson 2006c)

■ **RABBITS, RODENTS, SMALL MAMMALS:**

- Rabbits: 10–15 mg/kg PO q12h (Ivey and Morrissey 2000)
- Rabbits: For coccidiosis: 25 mg/kg PO once daily (Burke 1999)
- Hedgehogs: 2–20 mg/kg/day IM, SC or PO (Smith 2000)
- Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: As a coccidiostat: 50 mg/kg PO once, then 25 mg/kg PO once daily for 10–20 days or 75 mg/kg PO for 7–14 days (Adamcak and Otten 2000)

■ **CATTLE:**

For susceptible infections:

- 110 mg/kg PO or IV once daily (Upson 1988)
- 55 mg/kg IV initially, then 27.5 mg/kg IV once daily (Baggot 1983)
- 110 mg/kg, PO q24h (Burrows 1980)
- 55 mg/kg PO or IV initially, then 27.5 mg/kg q24h (Jenkins 1986)
- 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV or PO for up to 5 days. If using sustained release boluses: 137.5 mg/kg PO every 4 days (Package insert; *Albon*®—Roche)

■ **HORSES:**

For susceptible infections:

- 55 mg/kg, PO or IV q12h (Upson 1988)
- 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV (Package insert; *Albon*®—Roche)

■ **REPTILES:**

For susceptible infections:

- For coccidia: 90 mg/kg PO on day one and then 45 mg/kg PO on 5 successive days; may also be given IM or IV. Maintain adequate hydration. (Lewbart 2001)

Chemistry/Synonyms

A long-acting sulfonamide, sulfadimethoxine occurs as an odorless or almost odorless, creamy white powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadimethoxine may also be known as: solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, *Albon*®, *Amtech*®, *Chemiosalfa*®, *Deltin*®, *Di-Methox*®, *Risulpir*®, *Ritarsulfa*®, *SDM*®, *Sulfadren*®, *Sulfastop*®, or *Sulfasol*®, and *Sulfathox*®.

Storage/Stability

Unless otherwise instructed by the manufacturer, store sulfadimethoxine products at room temperature and protect from light. If crystals form due to exposure to cold temperatures, either warm the vial or store at room temperature for several days to resolubilize the drug; efficacy is not impaired by this process.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Sulfadimethoxine Injection: 400 mg/mL (40%) in 100 mL vials; *Albon*® Injection 40% (Pfizer Animal Health); *Amtech*® Sulfadimethoxine Injection 40% (IV use only in cattle) (Phoenix Scientific), *Di-Methox*® Injection 40% (AgriLabs), generic; (Agripharm, Aspen, Butler, Durvet, Vedco), *SDM*® Injection (Phoenix Pharmaceutical); (Rx) Approved for use in dogs, cats, horses, swine and cattle. Not to be used in horses intended for food or calves to be processed for veal. Slaughter withdrawal (at labeled doses) = 5 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Tablets: 125 mg, 250 mg, and 500 mg; *Albon*® Tablets (Pfizer Animal Health); (Rx). Approved for use in dogs and cats.

Sulfadimethoxine Oral Suspension: 50 mg/mL in 2 oz. and 16 oz. Bottles; *Albon*® (Pfizer); (Rx). Approved for use in dogs and cats.

Sulfadimethoxine Oral Boluses: 5 g, and 15 g; *Albon*® (Pfizer); (OTC). Approved for use in cattle. Not to be used in calves to be processed for veal. No withdrawal period has been established for this in pre-ruminating calves. Slaughter withdrawal (at labeled doses) = 7 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Boluses Sustained-Release: 12.5 g; *Albon*® SR (Pfizer); (Rx) Approved for use in non-lactating cattle. Slaughter

withdrawal (at labeled doses) = 21 days (cattle), a withdrawal period has not been established for pre-ruminating calves. Not for use in calves intended to be processed for veal.

Sulfadimethoxine Soluble Powder: 94.6 g/packet (for addition to drinking water); *Albon*® (Pfizer), *Di-Methox*® Soluble Powder (Agri-Labs), generic; (AgriPharm, Aspen, Durvet, Phoenix Scientific, Vedco), *Sulfasol*® (Med-Pharmex); (OTC) Approved for use in dairy calves, dairy heifers, beef cattle, broiler and replacement chickens only, and meat-producing turkeys. Slaughter withdrawal (at labeled doses) = 7 days (cattle); 5 days (poultry—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

Sulfadimethoxine 12.5% Concentrated Solution (for addition to drinking water): *Albon*® (Pfizer), *Amtech*® generic; (Phoenix Scientific), *Di-Methox*® Oral Solution (AgriLabs), *SDM*® Solution (Phoenix Pharmaceutical), generic; (AgriPharm, Aspen, Butler, Durvet, Vedco), *Sulforal*® (Med-Pharmex); (OTC). Approved for use in chickens, turkeys and cattle. Slaughter withdrawal (at labeled doses) = 7 days (for dairy calves, dairy heifers and beef cattle only. Withdrawal for pre-ruminating calves has not been established) Not to be used in calves to be processed for veal; 5 days (poultry—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

HUMAN-LABELED PRODUCTS: None

SULFADIMETHOXINE/ ORMETOPRIM

(or-me-toe-prim) Primor®

POTENTIATED SULFONAMIDE ANTIMICROBIAL

Prescriber Highlights

- ▶ Potentiated sulfa similar to trimethoprim/sulfa. The following apply to TMP/Sulfa & may correlate to this agent as well:
- ▶ Contraindications: Hypersensitive to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
- ▶ Caution: Diminished renal or hepatic function, or urinary obstruction or urolithiasis
- ▶ Adverse Effects: DOGS: Keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3) acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemias, agranulocytosis, idiosyncratic hepatic necrosis in dogs. CATS: Anorexia, crystalluria, hematuria, leukopenias & anemias
- ▶ Potentially teratogenic, weigh risk vs. benefit

Uses/Indications

Sulfadimethoxine/ormetoprim is approved for the treatment of skin and soft tissue infections in dogs caused by susceptible strains of *Staphylococcus aureus* and *E. coli*.

Pharmacology/Actions

Sulfadimethoxine/ormetoprim shares mechanisms of action and probably the bacterial spectrum of activity with trimethoprim/sulfa. Alone, sulfonamides are bacteriostatic agents, but in combination with either ormetoprim or trimethoprim, the potentiated sulfas are bactericidal. Potentiated sulfas sequentially inhibit enzymes in the

folic acid pathway, thereby inhibiting bacterial thymidine synthesis. The sulfonamide blocks the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA) and ormetoprim blocks the conversion of DFA to tetrahydrofolic acid by inhibiting dihydrofolate reductase.

The potentiated sulfas have a fairly broad spectrum of activity. Gram-positive bacteria that are generally susceptible include most streptococci, many strains of staphylococcus, and *Nocardia*. Many gram-negative organisms of the family Enterobacteriaceae are susceptible to the potentiated sulfas, but not *Pseudomonas aeruginosa*. Some protozoa (*Pneumocystis carinii*, Coccidia and Toxoplasma) are also inhibited by the combination. Potentiated sulfas reportedly have little activity against most anaerobes, but opinions on this vary.

Resistance will develop more slowly to the combination of drugs, than to either one alone. In gram-negative organisms, resistance is usually plasmid-mediated.

Pharmacokinetics

The pharmacokinetics of sulfadimethoxine are outlined in the previous monograph. Pharmacokinetic data for ormetoprim is not available at the time of this writing, but the manufacturer states that therapeutic levels are maintained over 24 hours at recommended doses.

Contraindications/Precautions/Warnings

The manufacturer states that ormetoprim/sulfadimethoxine should not be used in dogs showing marked liver parenchymal damage, blood dyscrasias, or in those with a history of sulfonamide sensitivity.

This combination should be used with caution in patients with pre-existing hepatic or thyroid disease.

Adverse Effects

This combination would be expected to exhibit an adverse reaction profile in dogs similar to that seen with trimethoprim/sulfa, including: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria, and cholestasis. Acute hypersensitivity reactions manifesting as Type I, (anaphylaxis) or Type III reaction (serum sickness) can also be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers may possibly be more susceptible to this effect than other breeds. Other hematologic effects (anemias, agranulocytosis) are possible, but fairly rare.

Long-term (8 weeks) therapy at recommended doses with ormetoprim/sulfadimethoxine (27.5 mg/kg once daily) resulted in elevated serum cholesterol, thyroid and liver weights, mild follicular thyroid hyperplasia, and enlarged basophilic cells in the pituitary. The manufacturer states that the principal treatment-related effect of extended or excessive usage is hypothyroidism.

Reproductive/Nursing Safety

Safety of ormetoprim/sulfadimethoxine has not been established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported in some lab animals with trimethoprim/sulfa.

Overdosage/Acute Toxicity

In experimental studies in dogs, doses greater than 80 mg/kg resulted in slight tremors and increased motor activity in some dogs. Higher doses may result in depression, anorexia, or seizures.

It is suggested that very high oral overdoses be handled by emptying the gut using standard precautions and protocols and by treating clinical signs supportively and symptomatically.

Drug Interactions; Laboratory Considerations

None have been noted for this combination, but it would be expected that the potential interactions outlined for the trimethoprim/sulfa monograph would also apply to this combination; refer to that monograph for more information.

Doses**■ DOGS:**

For susceptible infections:

- a) Initially 55 mg/kg (combined drug) PO on the first day of therapy, then 27.5 mg/kg PO once daily for at least 2 days after remission of clinical signs. Not approved for treatment longer than 21 days. (Package insert; *Primor*®—Pfizer)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Animals must be allowed free access to water and must not become dehydrated while on therapy.

Chemistry/Synonyms

A diaminopyrimidine structurally related to trimethoprim, ormetoprim occurs as a white, almost tasteless powder. The chemistry of sulfadimethoxine is described in the previous monograph.

Sulfadimethoxine may also be known as: solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, *Chemiosalfa*®, *Deltin*®, *Risulpir*®, *Ritarsulfa*®, *Sulfadren*®, *Sulfastop*®, or *Sulfathox*®.

Ormetoprim may also be known as NSC-95072, ormetoprima, ormetoprima, ormetoprimum, or Ro-5-9754.

Storage/Stability

Unless otherwise instructed by the manufacturer, store tablets in tight, light resistant containers at room temperature.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Sulfadimethoxine/Ormetoprim Tablets (scored)

120's: 100 mg Sulfadimethoxine, 20 mg Ormetoprim

240's: 200 mg Sulfadimethoxine, 40 mg Ormetoprim

600's: 500 mg Sulfadimethoxine, 100 mg Ormetoprim

1200's: 1000 mg Sulfadimethoxine, 200 mg Ormetoprim; *Primor*® (Pfizer); (Rx) Approved for use in dogs.

Sulfadimethoxine/Ormetoprim medicated premix: 113.5 g sulfadimethoxine and 68.1 g ormetoprim per pound in 50 lb bags. Approved for use in chickens [broilers, replacements (breeders and layers)], turkeys, ducks, & Chukar partridges. Slaughter withdrawal (at labeled doses) = 5 days. Do not feed to chickens over 16 weeks or age, turkeys or ducks producing eggs for food. *Rofenaid*® 40 (Alpharma), *Romet*® 30 (Alpharma)—Approved for use in salmonids (trout and salmon) and catfish. Slaughter or release as stocker fish = 42 days. (OTC)

HUMAN-LABELED PRODUCTS: None

SULFASALAZINE

(sul-fa-sal-a-zeen) Azulfidine®

**SULFONAMIDE/SALICYLATE ANTIBACTERIAL/
IMMUNOSUPPRESSIVE**

Prescriber Highlights

- Sulfa-analog that has GI antibacterial & antiinflammatory activity used for inflammatory bowel disease; has also been used for vasculitis
- Contraindications: Hypersensitivity to it, sulfas or salicylates; intestinal or urinary obstructions
- Caution: Liver, renal or hematologic diseases; cats
- Adverse Effects: DOGS: Keratoconjunctivitis sicca, anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, vomiting, decreased sperm counts & an allergic dermatitis. CATS: Anorexia, vomiting, anemias

Uses/Indications

Sulfasalazine is used for the treatment of inflammatory bowel disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs.

Pharmacology/Actions

While the exact mechanism of action for its therapeutic effects in treating colitis in small animals has not been determined, it is believed that after sulfasalazine is cleaved into sulfapyridine and 5-aminosalicylic acid (5-ASA, mesalamine) by bacteria in the gut the antibacterial (sulfapyridine) and/or antiinflammatory (mesalamine) activity alters the clinical signs/course of the disease. Levels of both drugs in the colon are higher then by giving them orally as separate agents.

Pharmacokinetics

Only about 10–33% of an orally administered dose of sulfasalazine is absorbed. Apparently, some of this absorbed drug is then excreted unchanged in the bile. Unabsorbed and biliary excreted drug is cleaved into 5-ASA and sulfapyridine in the colon by bacterial flora. The sulfapyridine component is rapidly absorbed, but only a small percentage of the 5-ASA is absorbed.

Absorbed sulfapyridine and 5-ASA are hepatically metabolized and then renally excreted.

Contraindications/Precautions/Warnings

Sulfasalazine is contraindicated in animals hypersensitive to it, sulfonamides or salicylates. It is also contraindicated in patients with intestinal or urinary obstructions. It should be used with caution in animals with preexisting liver, renal or hematologic diseases. Because cats can be sensitive to salicylates (see the aspirin monograph), use caution when using this drug in this species.

Adverse Effects

Although adverse effects do occur in dogs, with keratoconjunctivitis sicca (KCS) reported most frequently, they are considered to occur relatively uncommonly. Other potential adverse effects include anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, vomiting, decreased sperm counts and an allergic dermatitis. Should decreased tear production be noted early, either reducing the dose or discontinuing the drug may prevent progression of KCS or increase tear production.

Cats can occasionally develop anorexia and vomiting which may be alleviated by use of the enteric-coated tablets. Anemias secondary to sulfasalazine are also potentially possible in cats.

Reproductive/Nursing Safety

Although sulfasalazine has not been proven harmful to use during pregnancy and incidences of neonatal kernicterus in infants born to women taking sulfasalazine are low, it should only be used when clearly indicated. In laboratory animal studies (rats, rabbits), doses of six times normal (human) caused impairment of fertility in male animals; this effect is thought to be caused by the sulfapyridine component and was reversible upon discontinuation of the drug.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Sulfonamides are excreted in milk. In human newborns, they compete with bilirubin for binding sites on plasma proteins and may cause kernicterus. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Little specific information is available regarding overdoses with this agent, but because massive overdoses could cause significant salicylate and/or sulfonamide toxicity, standard protocols (empty stomach, cathartics, etc.) should be considered. Urine alkalinization and forced diuresis may also be beneficial in selected cases.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfasalazine and may be of significance in veterinary patients:

- **CHLORPROPAMIDE:** Hypoglycemic effects could be potentiated
- **DIGOXIN:** Sulfasalazine may reduce absorption
- **FEROUS SULFATE** or **other iron salts:** May decrease the blood levels of sulfasalazine if administered concurrently; clinical significance is unknown
- **FOLIC ACID:** Oral absorption may be inhibited
- **WARFARIN:** Potentially sulfasalazine could potentiate warfarin

Doses

■ DOGS:

For inflammatory large bowel disease:

- a) 20–30 mg/kg q8–12h PO. (Hall 2004)
- b) 10–15 mg/kg PO q8–12h for 2 weeks tapered to the lowest effective dose (Moore 2004)
- c) 20–48.4 mg/kg (maximum total dose of one gram in refractory patients) PO q8h. May consider an initial dose of 12.5 mg/kg, q8h. Continue initial dose for a minimum of 4 weeks before modifying dosage. After signs of disease resolve, reduce dosage by 25% at 2 week intervals and eventually discontinue while maintaining dietary management. (Jergens and Willard 2000)
- d) For chronic colitis: If hypoallergenic diet does not control signs, sulfasalazine 20–50 mg/kg (up to a maximum of 1 gram) three times daily. Initial dosage usually 20–30 mg/kg three times daily. Dose may be reduced at 2–4 week intervals

if stool remains normal using the following protocol: Initially same dose given twice daily, then 50% of initial dose twice daily, then 50% of that dose once daily, then discontinue. Some dogs may require chronic therapy. (Leib 2000)

- e) Usual initial dose is 20–40 mg/kg q8h for 3 weeks, followed by 20–40 mg/kg PO q12h for 3 weeks, then 10–20 mg/kg q12h for 3 weeks. (Marks 2007b)
- f) 10–25 mg/kg PO three times a day for 4–6 weeks. With resolution of clinical signs, reduce dose by 25 percent at 2 week intervals and eventually discontinue while maintaining dietary management. (Washabau 2005)

For adjunctive treatment of vasculitis:

- a) 20–40 mg/kg PO q8h (Hillier 2006d), (Griffin 2006)
- b) 25 mg/kg PO three times a day. (Bloom 2006b)

■ CATS:

For inflammatory large bowel disease:

- a) 10–20 mg/kg PO once daily. Use cautiously in cats because of their sensitivity to salicylates (Jergens and Willard 2000)
- b) 10–20 mg/kg PO q24 hours (once daily) tapered to the lowest effective dose (Moore 2004), (Marks 2007b)
- c) 10–20 mg/kg PO q8–12h (maximum of 10 days) (Dimski 1995)
- d) 10–20 mg/kg PO q8–24h; up to a maximum of 10 days treatment (Krecic 2002)

■ FERRETS:

- a) 10–20 mg/kg PO 2–3 times a day (Williams 2000)
- b) 25 mg (total dose) PO twice daily (Weiss 2002b)

Monitoring

■ Efficacy

■ Adverse effects, particularly KCS; Schirmer tear tests should be performed prior to therapy (and on rechecks), especially in middle-aged to older dogs

■ Occasional CBC, liver function tests are warranted with chronic therapy

Client Information

■ Clients should monitor for clinical signs of KCS (dry cornea, blepharospasm, bilateral mucopurulent discharge) and report them to the veterinarian immediately.

Chemistry/Synonyms

Sulfasalazine is basically a molecule of sulfapyridine linked by a diazo bond to the diazonium salt of salicylic acid. It occurs as an odorless, bright yellow to brownish-yellow fine powder. Less than 0.1 mg is soluble in 1 mL of water and about 0.34 mg is soluble in 1 mL of alcohol.

Sulfasalazine may also be known as: salazosulfapyridine, salicylazosulfapyridine, sulfasalazinum, sulphasalazine, *Azulfidine*®, *Aculfin*®, *Azulfin*®, *Colo-Pleon*®, *Pleon RA*®, *Pyralin*®, *SAS*®, *Salazine*®, *Salazopirina*®, *Salazoprin*®, *Salazopyrin*®, *Salazopyrina*®, *Salazopyrine*®, *Salisulf Gastroprotetto*®, *Salopyrine*®, *Saridine*®, *Sazo*®, *Sulazine*®, or *Ulco*®.

Storage/Stability

Sulfasalazine tablets (either plain or enteric-coated) should be stored at temperatures less than 40°C and preferably at room temperature (15–30°C, 59–86°F) in well-closed containers. The oral suspension should be stored at room temperature (15–30°C, 59–86°F); avoid freezing.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Sulfasalazine Tablets: 500 mg; *Azulfidine*® (Pfizer); (Rx); generic; (Rx)Sulfasalazine Delayed-Release Tablets: 500 mg (enteric coated); *Azulfidine*® *EN-tabs*® (Pfizer); (Rx)**Syrup of Ipecac**—see **Ipecac Syrup****TAURINE****(tor-eeen)****AMINO ACID NUTRITIONAL****Prescriber Highlights**

- ▶ Amino acid used primarily for the treatment of taurine deficiency cardiomyopathies in cats & dogs
- ▶ May also be useful for many other conditions (e.g., seizures), but little supporting data available
- ▶ Very low toxic potential
- ▶ Laboratory considerations

Uses/Indications

Taurine has proven beneficial in preventing retinal degeneration and the prevention and treatment of taurine-deficiency dilated cardiomyopathy in cats. Although modern commercial feline diets have added taurine, some cats still develop taurine-deficiency associated dilated cardiomyopathy. It may also be of benefit in taurine (\pm carnitine) deficient cardiomyopathy in American Cocker Spaniels and certain other breeds such as, Golden Retrievers, Labrador Retrievers, Newfoundlands, Dalmations, Portuguese Water Dogs, and English Bulldogs. Preliminary studies have shown evidence that it may be useful as adjunctive treatment for cardiac disease in animals even if taurine deficiency is not present. Because of its low toxicity, some have suggested it be tried for a multitude of conditions in humans and animals; unfortunately, little scientific evidence exists for these uses.

Pharmacology/Actions

While classically considered a “non-essential” nutrient, taurine has been found to play several “essential” roles in various mammalian species. Taurine is important for bile acid conjugation, especially in cats and dogs. *In vivo*, taurine is synthesized from methionine. Cysteinesulfinic acid decarboxylase (CSAD) and vitamin B₆ are involved with this synthesis. Deficiencies of either will depress taurine synthesis. Cats are particularly susceptible to taurine deficiency as they have low CSAD activity and use taurine almost exclusively for bile acid conjugation.

Additionally taurine is important in the modulation of calcium flux, thereby reducing platelet aggregation, stabilizing neuronal membranes, and affecting cardiac function. Taurine’s effects on cardiac function include positive inotropic activity without affecting resting potential and modulating ionic currents across the cell membrane. Taurine is important for normal development of the CNS and it has a GABA-like effect that may make it useful for treating some seizure disorders.

Pharmacokinetics

No specific information was located. Excess taurine is rapidly excreted in the kidneys, but if a deficiency exists, urinary excretion is reduced via reabsorption.

Contraindications/Precautions/Warnings

While taurine is safe, it should not be used as a substitute for adequate diagnosis.

Adverse Effects

Taurine appears to be very well tolerated. Minor GI distress potentially could occur after oral dosing.

Overdosage/Acute Toxicity

No specific information was located, but toxic potential appears to be very low.

Drug Interactions

None are reported.

Laboratory Considerations

- Because plasma levels may reflect the acute changes associated with dosing, whole blood levels are preferred to measure actual status of taurine in the body. Because intracellular levels of taurine are much higher than in plasma, hemolysis or collection of the buffy coat will negate the results.

Doses**■ DOGS:**

- a) For taurine-deficiency related cardiomyopathy: In American Cocker Spaniels: Give 500 mg taurine PO q12h (with 1 gram of carnitine PO q12h) (Kittleson 2000)
- b) Complementary therapy for seizures: 400 mg/40 lbs of body weight PO twice daily. “May” help decrease seizure activity (Neer 2000)

■ CATS:

- a) For taurine-deficiency related cardiomyopathy: 250 mg (per cat) PO q12–24h. Because taurine is safe and inexpensive, recommend using for any case of myocardial failure. (Fox 2000)
- b) Complementary therapy for seizures: 500 mg Per cat PO twice daily. “May” help decrease seizure activity (Neer 2000)

Monitoring

- Clinical efficacy
- Taurine levels (if possible and affordable; whole blood levels preferable to plasma/serum levels)

Chemistry/Synonyms

Taurine, an amino acid also known as 2-aminosulphonic acid, has a molecular wt. of 125. Solubility in 100 mL of water at 20°C is 8.8 grams.

Storage/Stability

Unless otherwise labeled, store taurine tablets or capsules at room temperature. Protect from light and moisture.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

The following products are labeled for use in animals:

Taurine Tablets: 250 mg; *Formula V*® *Taurine Tablets* (PetAg); Labeled for use in cats.

Taurine Liquid: 375 mg/4 mL (one pump); *Dyna-Taurine*® (Harlmen); Labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

There are several oral dosage form products available for taurine. Technically considered a “nutrient” they are all OTC and may need to be obtained from health food stores. Most dosage forms available range from 125 mg to 500 mg.

TEPOXALIN

(te-pox-a-lin) Zubrin®

NONSTEROIDAL ANTIINFLAMMATORY AGENT**Prescriber Highlights**

- ▶ NSAID dual inhibitor of COX & LOX indicated for the treatment of pain & inflammation associated with osteoarthritis in dogs
- ▶ Adverse effect profile still being determined, but may cause more vomiting & diarrhea than some other approved NSAIDs
- ▶ Rapidly disintegrating tablet dosage form may be useful in difficult to pill dogs

Uses/Indications

Tepoxalin is indicated for the treatment of pain and inflammation associated with osteoarthritis in dogs. Because of the drug's inhibitory effects on leukotrienes, there is interest in seeing if it would be beneficial in the adjunctive treatment of allergic conditions in dogs.

Pharmacology/Actions

Tepoxalin is a dual inhibitor of both cyclooxygenase (COX) and 5-lipoxygenase (LOX). It inhibits both COX-1 and COX-2 enzymes, but it is not clear if it is COX-2 preferential in the dog (it is not COX-2 preferential in sheep uterine cells) or if its LOX inhibition reduces the adverse effects associated with COX-1 inhibition. By inhibiting COX-2 enzymes, tepoxalin reduces the production of prostaglandins associated with pain, hyperpyrexia and inflammation. Its inhibition of LOX potentially reduces the production of leukotrienes, including leukotriene B₄. As leukotriene B₄ may contribute to increased GI tract inflammation by increasing cytokine production, neutrophil longevity and release of proteinases, inhibition may reduce the GI effects routinely seen in dogs with COX-1 inhibitors. Leukotrienes may also contribute to inflammatory responses seen in osteoarthritic conditions and their inhibition could reduce clinical signs seen with the condition.

Pharmacokinetics

After oral administration to dogs, tepoxalin is readily absorbed and peak levels occur between 2–3 hours post-dose. The presence of food in the gut increases bioavailability. Tepoxalin is rapidly metabolized to several metabolites, including one that is active (tepoxalin pyrazole acid). Tepoxalin and tepoxalin pyrazole acid are highly bound to plasma proteins (98–99%). Elimination half-lives for tepoxalin and tepoxalin pyrazole acid are about 2 hours and 13 hours, respectively. Metabolites are eliminated in the feces; only 1% of the drug is eliminated in the urine.

Contraindications/Precautions/Warnings

Tepoxalin is contraindicated in dogs demonstrating prior hypersensitivity reactions to tepoxalin. It should be used with caution in patients with impaired hepatic, cardiovascular or renal function, or at risk for developing nephrotoxic effects associated with NSAIDs

(i.e., dehydrated or on concomitant diuretic therapy). Patients with active gastrointestinal ulcers should probably not receive this drug. Dogs weighing less than 3 kg cannot be accurately dosed with available dosage forms. Safety in dogs less than 6 months old has not been established.

Adverse Effects

Adverse effects most likely seen in dogs include diarrhea, vomiting, anorexia/inappetence, enteritis, and lethargy. In one study where dogs received labeled doses for 4 weeks, 22% of dogs developed diarrhea and 20% vomited. It is unknown if giving the drug with food will decrease vomiting incidence. Other adverse effects reported (incidences <1%) include incoordination, incontinence, increased appetite, eating grass, flatulence, hair loss, and trembling.

The manufacturer warns to discontinue the drug if signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus, or lethargy are observed. Safety studies in dogs less than 6 months of age have not been completed.

Reproductive/Nursing Safety

Safety of this drug has not been determined in pregnant, breeding, or lactating dogs; use with caution and with informed consent of client.

Overdosage/Acute Toxicity

Information on acute overdosage of tepoxalin was not located. Dogs receiving 300 mg/kg/day for 6 months showed decreases in total protein, albumin and calcium concentrations. At necropsy, all dogs showed gastric lesions. An acute overdose may cause significant GI distress and ulceration with GI bleeding. It is suggested to treat supportively and monitor CBC, hydration, renal function, and for evidence of GI bleeding. Contact an animal poison control center for more information.

Drug Interactions

A study in normal dogs showed no significant changes in renal function when **enalapril** was used with tepoxalin.

The following drug interactions have either been reported or are theoretical in humans or animals receiving tepoxalin and may be of significance in veterinary patients:

- **ASPIRIN:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS:** As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tepoxalin
- **DIGOXIN:** NSAIDs may increase serum levels
- **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans, it is unknown if fluconazole affects tepoxalin levels in dogs
- **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS** (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **WARFARIN:** The manufacturer cautions to closely monitor patients also receiving drugs that are highly bound to plasma proteins (e.g., warfarin), as tepoxalin and its active metabolite are 98–99% protein bound in the dog

Laboratory Considerations

No specific laboratory interactions or considerations noted

Doses**■ DOGS:**

For pain and inflammation associated with osteoarthritis:

- a) On first day of treatment give 20 mg/kg PO (or 10 mg/kg PO); subsequently give 10 mg/kg PO once daily. Duration of treatment should be based on clinical response and patient tolerance to therapy. (Package insert; *Zubrin*®—Schering-Plough)

Monitoring

- Clinical efficacy
- Baseline and periodic CBC, chemistry panel (including bilirubin and serum creatinine)
- Signs associated with adverse effects (GI effects, appetite, vomiting, diarrhea, etc.)

Client Information

- When dosing, the person administering the tablet should place it in dog's mouth and hold mouth closed for approximately 4 seconds to assure tablet disintegration
- Absorption may be enhanced (and vomiting reduced?) if given with food
- Owners should be instructed to discontinue the drug and contact their veterinarian if diarrhea is severe or persists, or signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus or lethargy are observed
- Dogs should have access to water; dehydration should be avoided
- The manufacturer provides a client information sheet and states to "Always provide client information sheet . . ."

Chemistry/Synonyms

A non-steroidal antiinflammatory agent (NSAID), tepoxalin occurs as a white, tasteless, crystalline material that is insoluble in water and soluble in alcohol and most organic solvents. The commercially available tablets contain a micronized form of the drug in a highly porous matrix that rapidly disintegrates in the mouth. Drug particles are released into the saliva and swallowed by the dog where it is absorbed in the intestines.

Tepoxalin may also be known as ORF-20485, RWJ-20485 and *Zubrin*®.

Storage/Stability

Tablets should be kept in their foil blister packs until used and stored at temperatures between 2–30°C (36–86°F).

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Tepoxalin Oral (rapidly-disintegrating) Tablets: 30 mg, 50 mg, 100 mg, 200 mg in foil blisters containing 10 tablets in boxes of 10 foil blisters; *Zubrin*® (Schering-Plough); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS: None**TERBINAFINE HCL (SYSTEMIC)**

(ter-*bin*-ah-fin) Lamisil®

ANTIFUNGAL**Prescriber Highlights**

- Oral & topical antifungal; used primarily for dermatophytic infections, but may be useful for other fungi (e.g., aspergillus), especially in birds
- Comparatively (with azole antifungals) few drug interactions
- Appears to be very well tolerated, but limited experience; vomiting most likely adverse effect
- Caution if liver or renal disease
- Treatment is relatively expensive, but generics are now available

Uses/Indications

Terbinafine may be useful for treating dermatophytic and other fungal infections in dogs and cats.

Terbinafine may also be useful for treating birds for systemic mycotic (e.g., aspergillosis) infections.

Pharmacology/Actions

Terbinafine is an inhibitor of the synthesis of ergosterol, a component of fungal cell membranes. By blocking the enzyme squalene monooxygenase (squalene 2,3-epoxidase), terbinafine inhibits the conversion of squalene to sterols (especially ergosterol) and causes accumulation of squalene. Both these effects are thought to contribute to its antifungal action. Terbinafine's mechanism for inhibiting ergosterol is different from the azole antifungals.

Unlike the azole agents, terbinafine's actions are not mediated via the cytochrome P-450 enzyme system, and, therefore, do not have the concerns of drug interactions or altering testosterone or cortisol.

Terbinafine primarily has clinical activity (fungicidal) against dermatophytic organisms (*Microsporum* spp., *Trichophyton* spp., etc.). It may only be fungistatic against the yeasts (*Candida* spp.). Terbinafine has activity against *Aspergillus*, *Blastomyces*, and *Histoplasma* but is usually not used clinically for infections caused by these organisms.

Pharmacokinetics

Little veterinary specific information is available. In cats dosed at 34–46 mg/kg PO once daily for 14 days terbinafine persisted in hair above MIC for several weeks. (Foust, Marsella et al. 2007)

In humans, terbinafine given orally is greater than 70% absorbed; after first pass, metabolism bioavailability is about 40%. Food may enhance absorption somewhat. Terbinafine is distributed to skin and into the sebum. Over 99% of drug in plasma is bound to plasma proteins. Drug in the circulation is metabolized in the liver and the effective elimination half-life is about 36 hours. The drug may persist in adipose tissue and skin for very long periods.

Contraindications/Precautions/Warnings

Terbinafine is contraindicated in patients hypersensitive to it. The manufacturer does not recommend its use in patients with active or chronic liver disease or with significantly impaired renal function. If terbinafine is to be used in veterinary patients with markedly impaired liver or renal function, do so with extreme caution; dosage adjustments should be considered.

Adverse Effects

Because of limited usage in veterinary patients the adverse effect profile is not well defined, but thus far, the drug appears to be well tolerated. GI effects (vomiting, inappetence, diarrhea) are possible.

Very rarely in humans, liver failure, neutropenia or serious skin reactions (e.g., TEN, Stevens-Johnson syndrome) have occurred after terbinafine use.

Reproductive/Nursing Safety

High dose studies in pregnant rabbits and rats have not demonstrated overt fetotoxicity or teratogenicity, but definitive safety in pregnancy has not been determined. Use with caution (manufacturer recommends NOT using in pregnant women). In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

The drug enters maternal milk at levels 7 times that found in plasma; the manufacturer recommends that mothers not nurse while taking this drug. Use with caution in nursing veterinary patients.

Overdosage/Acute Toxicity

Limited information; humans have taken doses of up to 5 grams without serious effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving terbinafine and may be of significance in veterinary patients:

■ **CYCLOSPORINE:** Terbinafine may increase the elimination of cyclosporine

■ **RIFAMPIN:** May increase terbinafine clearance

As it shares the same metabolic pathway (CYP2D6), terbinafine could affect the metabolism of:

■ **BETA-BLOCKERS**

■ **MAO INHIBITORS** (amitraz, selegiline)

■ **SSRI'S** (fluoxetine, etc.)

■ **TRICYCLIC ANTIDEPRESSANTS**

Laboratory Considerations

No apparent issues

Doses

■ DOGS & CATS:

For dermatophytic infections:

- 30–40 mg/kg PO once daily (Moriello 2004)
- 30 mg/kg PO once daily. Treatment should continue until two successive brush cultures (separated by two weeks) are negative. First culture can be taken 3–4 weeks after starting therapy. (Foil 2003b)
- In cases where other drugs are not tolerated: 25 mg/kg PO q24h. (Rosenkrantz 2006a)

For adjunctive treatment (with topical therapy) of nasal *Aspergillus* infections if the cribriform plate is penetrated:

- 5–10 mg/kg PO q12h for 3–6 months (Kuehn 2007)

For pythiosis where advanced disease precludes complete surgical excision:

- 10 mg/kg PO q24h with itraconazole (10 mg/kg PO twice daily) (Marks 2007a)

For lagendiosis where disease precludes complete surgical excision:

- 5–10 mg/kg PO q24h with itraconazole (10 mg/kg PO q24h) with repeated aggressive surgical resection was effective in one dog with multifocal cutaneous lesions, but no systemic lesions. (Grooters 2007)

■ BIRDS:

For avian mycotic infections:

- 10–15 mg/kg PO q12–24h (Dalhausen, Lindstrom et al. 2000)
- 10–15 mg/kg PO q12–24h (suspend a 250 mg tablet in 25 mL water); Nebulization: 1 mg/mL (500 mg terbinafine plus 1 mL *Mucomyst*® plus 500 mL of distilled water). Terbinafine can be used in combination with itraconazole. (Flammer 2003a)

Monitoring

■ Clinical efficacy

■ Baseline liver enzymes and then as needed (especially if treating long-term)

Client Information

■ Costs of treating can be considerable

■ Give with food, particularly if vomiting is a problem

Chemistry/Synonyms

A synthetic allylamine antifungal, terbinafine HCl occurs as a white to off-white, fine, crystalline powder. It is slightly soluble in water and soluble in ethanol.

Terbinafine HCl may also be known as: *Alamil*®, *Daskil*®, *Daskyl*®, *DesenexMax*®, *Finex*®, *Lamisil*®, *Maditez*®, *Micosil*®, or *Terekol*®.

Storage/Stability

Terbinafine tablets should be stored at room temperature, in tight containers; protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Terbinafine HCl Tablets: 250 mg; *Lamisil*® (Novartis), generic; (Rx)

A topical cream and spray (1%) are also available (Rx).

TERBUTALINE SULFATE

(ter-byoo-ta-leen) Brethine®

BETA-ADRENERGIC AGONIST

Prescriber Highlights

- Beta agonist used as a bronchodilator & sometimes to treat bradyarrhythmias
- Contraindications: Hypersensitivity to terbutaline
- Caution: Diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias)
- Adverse Effects: Increased heart rate, tremors, CNS excitement (nervousness) & dizziness; after parenteral injection in horses, sweating & CNS excitation are possible

Uses/Indications

Terbutaline is used as a bronchodilating agent in the adjunctive treatment of cardiopulmonary diseases (including tracheobronchitis, collapsing trachea, pulmonary edema, and allergic bronchitis) in small animals. It may be of some benefit in treating bradyarrhythmias in dogs and cats.

Terbutaline has been used occasionally in horses for its bronchodilating effects, but adverse effects, short duration of activity after IV administration and poor oral absorption have limited its use. It has been shown to be useful as a diagnostic agent to diagnose anhidrosis in horses after intradermal injection.

Oral and intravenous terbutaline has been used successfully in humans for the inhibition of premature labor clinical signs.

Pharmacology/Actions

Terbutaline stimulates beta-adrenergic receptors found principally in bronchial, vascular, and uterine smooth muscles (beta₂); bronchial and vascular smooth muscle relaxation occurs with resultant reduced airway resistance. At usual doses it has little effect on cardiac (beta₁) receptors and usually does not cause direct cardiostimulatory effects. Occasionally, a tachycardia develops which may be a result of either direct beta stimulation or a reflex response secondary to peripheral vasodilation. Terbutaline has virtually no alpha-adrenergic activity.

Pharmacokinetics

The pharmacokinetics of this agent have apparently not been thoroughly studied in domestic animals. In humans, only about 33–50% of an oral dose is absorbed; peak bronchial effects occur within 2–3 hours and activity persists up to 8 hours. Terbutaline is well-absorbed following SC administration with an onset of action occurring within 15 minutes, peak effects at 30–60 minutes, and duration of activity up to 4 hours.

In horses, terbutaline is very poorly absorbed after oral administration with a bioavailability <1%. When given IV, mean residence time is about 30 minutes in horses and the drug probably needs to be given as a constant rate infusion if used therapeutically.

Terbutaline is distributed into milk at levels approximately 1% of the oral dose given to the mother. Terbutaline is principally excreted unchanged in the urine (60%), but is also metabolized in the liver to an inactive sulfate conjugate.

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or cardiomyopathy. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Adverse Effects

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents, including increased heart rate, tremors, CNS excitement (nervousness) and dizziness. These effects are generally transient, mild and do not require discontinuation of therapy. After parenteral injection in horses, sweating and CNS excitation have been reported.

Transient hypokalemia has been reported in humans receiving beta-adrenergic agents. If an animal is susceptible to developing hypokalemia, it is suggested that additional serum potassium monitoring be done early in therapy.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Terbutaline is excreted in milk. In humans, nursing is not recommended with systemic terbutaline therapy.

Overdosage/Acute Toxicity

Clinical signs of significant overdose after systemic administration may include arrhythmias (bradycardia, tachycardia, heart block, extrasystoles), hypertension, fever, vomiting, mydriasis, and CNS stimulation. If a recent oral ingestion, it should be handled like other overdoses (empty gut, give activated charcoal and a cathartic) if the animal does not have significant cardiac or CNS effects. If cardiac arrhythmias require treatment, a beta-blocking agent (e.g., propranolol) can be used, but may precipitate bronchoconstriction.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving terbutaline and may be of significance in veterinary patients:

- **ANESTHETICS, INHALATION** (e.g., halothane, isoflurane, methoxyflurane): Use with inhalation anesthetics may predispose the patient to ventricular arrhythmias, particularly in patients with preexisting cardiac disease—use cautiously
- **BETA-ADRENERGIC BLOCKING AGENTS** (e.g., propranolol): May antagonize the actions of terbutaline
- **DIGOXIN**: Use with digitalis glycosides may increase the risk of cardiac arrhythmias
- **MONOAMINE OXIDASE INHIBITORS**: May potentiate the vascular effects of terbutaline
- **SYMPATHOMIMETICS, OTHER**: Use of terbutaline with other sympathomimetic amines may increase the risk of developing adverse cardiovascular effects
- **TRICYCLIC ANTIDEPRESSANTS**: May potentiate the vascular effects of terbutaline

Doses

■ DOGS:

- a) For a trial to treat intrathoracic tracheal collapse, expiratory cough or dyspnea and marked exercise intolerance: 1.25–5 mg (total dose) PO two to three times daily (Johnson 2004c)
- b) As a bronchodilator in chronic bronchitis: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h (Johnson 2000)
- c) For bradyarrhythmias: 0.2 mg/kg PO q8–12h; improvement usually partial and often temporary (Rishniw and Thomas 2000)
- d) For treatment of premature labor: 0.03 mg/kg PO q8h or by continuous IV infusion to effect (Davidson 2004c)
- e) For tracheal collapse: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h; 0.01 mg/kg IV, IM or SC (Ettinger and Kantrowitz 2005)

■ CATS:

- For acute exacerbations of feline asthma treated at home: 0.01 mg/kg SC or IM; Beneficial response (decrease of respiratory rate or effort by 50%) occurs in 15–30 minutes. A heart rate that approaches 240 BPM indicates that the drug has been absorbed. (Padrid 2000)
- For feline asthma: 0.312–0.625 mg (total dose) per cat PO two to three times daily; may adjust dose up to 1.25 mg in larger cats if needed (Noone 1999)
- For bradyarrhythmias: 0.625 mg PO q8–12h; improvement usually partial and often temporary (Rishniw and Thomas 2000)
- For acute bronchoconstriction (initial crisis): 0.01 mg/kg IV, SC, IM (Cohn 2007)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- 0.0033 mg/kg IV (Robinson 1987)

Monitoring

- Clinical symptom improvement; auscultation
- Cardiac rate, rhythm (if indicated)
- Serum potassium, early in therapy if animal susceptible to hypokalemia

Client Information

- Contact veterinarian if animal's condition deteriorates or if it becomes acutely ill

Chemistry/Synonyms

A synthetic sympathomimetic amine, terbutaline sulfate occurs as a slightly bitter-tasting, white to gray-white, crystalline powder that may have a faint odor of acetic acid. One gram is soluble in 1.5 mL of water or 250 mL of alcohol. The commercially available injection has its pH adjusted to 3–5 with hydrochloric acid.

Terbutaline Sulfate may also be known as: KWD-2019, terbutaline sulphate, terbutalini sulfas; many trade names are available.

Storage/Stability/Compatibility

Terbutaline tablets should be stored in tight containers at room temperature (15–30°C). Tablets have an expiration date of 3 years beyond the date of manufacture. Terbutaline injection should be stored at room temperature (15–30°C) and protected from light. The injection has an expiration date of 2 years after the date of manufacture.

Terbutaline injection is stable over a pH range of 1–7. Discolored solutions should not be used. It is physically **compatible** with D₅W and aminophylline.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Terbutaline Sulfate Tablets: 2.5 mg & 5 mg; *Brethine*® (aaiPharma); generic; (Global) (Rx)

Terbutaline Injection: 1 mg/mL in 1 mL vials & 2 mL amps with 1 mL fill; *Brethine*® (aaiPharma); generic; (Rx)

TESTOSTERONE CYPIONATE TESTOSTERONE ENANTHATE TESTOSTERONE PROPIONATE

(tess-toss-ter-ohn)

ANDROGENIC HORMONE

Prescriber Highlights

- Principle endogenous androgen used primarily for the treatment of testosterone-responsive urinary incontinence in neutered male dogs/cats; in bovine medicine to produce an estrus-detector animal
- Contraindications: Known hypersensitivity to the drug; prostate carcinoma. Caution: Renal, cardiac, or hepatic dysfunction
- Adverse Effects: Uncommon, but perianal adenomas, perineal hernias, prostatic disorders, & behavior changes possible
- Testosterone products are controlled substances (C-III)

Uses/Indications

The use of injectable esters of testosterone in veterinary medicine is limited primarily to its use in dogs (and perhaps cats) for the treatment of testosterone-responsive urinary incontinence in neutered males. Testosterone has been used to treat a rare form of dermatitis (exhibited by bilateral alopecia) in neutered male dogs. These drugs are also used in bovine medicine to produce an estrus-detector (teaser) animal in cull cows, heifers, and steers.

The effectiveness of testosterone to increase libido, treat hypogonadism, aspermia, and infertility in domestic animals has been disappointing.

Pharmacology/Actions

The principle endogenous androgenic steroid, testosterone is responsible for many secondary sex characteristic of the male as well as the maturation and growth of the male reproductive organs and increasing libido.

Testosterone has anabolic activity with resultant increased protein anabolism and decreased protein catabolism. Testosterone causes nitrogen, sodium, potassium and phosphorus retention and decreases the urinary excretion of calcium. Nitrogen balance is improved only when an adequate intake of both calories and protein occurs.

By stimulating erythropoietic stimulating factor, testosterone can stimulate the production of red blood cells. Large doses of exogenous testosterone can inhibit spermatogenesis through a negative feedback mechanism inhibiting luteinizing hormone (LH).

Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.

Pharmacokinetics

Orally administered testosterone is rapidly metabolized by the GI mucosa and the liver (first-pass effect); very little reaches the systemic circulation. The esterified compounds, testosterone enanthate and cypionate are less polar than testosterone and more slowly absorbed from lipid tissue after IM injection. The duration of action of these compounds may persist for 2–4 weeks after IM injection. Testosterone propionate reportedly has a much shorter duration of

action than the enanthate or cypionate esters. Because absorption is dependent upon several factors (volume injected, perfusion, etc.), duration of action may be variable.

Testosterone is highly bound to a specific testosterone-estradiol globulin (98% in humans). The quantity of this globulin determines the amount of drug that is in the free or bound form. The free form concentration determines the plasma half-life of the hormone.

Testosterone is metabolized in the liver and is, with its metabolites, excreted in the urine ($\approx 90\%$) and the feces ($\approx 6\%$). The plasma half-life of testosterone has been reported to be between 10–100 minutes in humans. The plasma half-life of testosterone cypionate has been reported to be 8 days.

Contraindications/Precautions/Warnings

Testosterone therapy is contraindicated in patients with known hypersensitivity to the drug or prostate carcinoma. It should be used with caution in patients with renal, cardiac or hepatic dysfunction.

Adverse Effects

Adverse effects are reportedly uncommon when injectable testosterone products are used in male dogs to treat hormone-responsive incontinence. Perianal adenomas, perineal hernias, prostatic disorders, and behavior changes (aggression) are all possible, however. Behavioral changes have been reported in cats. Polycythemia has been reported in humans receiving high dosages of testosterone. High dosages or chronic usage may result in oligospermia or infertility in intact males.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *X* for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *D* (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

It is not known whether androgens are excreted in milk; consider using milk replacer if using testosterone in nursing patients.

Overdosage/Acute Toxicity

No specific information was located; refer to the Adverse Effects section for further information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving testosterone and may be of significance in veterinary patients:

- **CORTICOSTEROIDS:** Androgens may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN; ORAL ANTIDIABETIC AGENTS:** Testosterone may decrease serum glucose levels
- **PROPRANOLOL:** Testosterone cypionate may increase propranolol clearance
- **WARFARIN:** Testosterone may increase anticoagulant effects

Laboratory Considerations

- Concentrations of protein bound iodine (PBI) can be decreased in patients receiving testosterone therapy, but the clinical significance of this is probably not important. Androgen agents can decrease amounts of thyroxine-binding globulin and decrease **total T₄** concentrations and increase resin uptake of T₃ and T₄. Free thyroid hormones are unaltered and clinically, there is no evidence of dysfunction.

- Both **creatinine** and **creatinine** excretion can be decreased by testosterone
- Testosterone can increase the urinary excretion of **17-ketosteroids**
- Androgenic/anabolic steroids may alter **blood glucose** levels
- Androgenic/anabolic steroids may suppress **clotting factors II, V, VII, and X**

Doses

■ DOGS:

For testosterone-responsive urinary incontinence (may be used with phenylpropanolamine) in males:

- a) Testosterone propionate: approximately 2 mg/kg IM or SC 3 times per week. Testosterone cypionate: 200 mg IM once per month (LaBato 1988), (Polzin and Osborne 1985)
- b) Testosterone propionate: 2.2 mg/kg IM q2–3 days. Testosterone cypionate: 2.2 mg/kg IM once per month (Moreau and Lappin 1989), (Chew, DiBartola, and Fenner 1986)
- c) Testosterone cypionate: 2.2 mg/kg IM q4–8 weeks (Lane 2002b)
- d) Testosterone propionate: 2.2 mg/kg IM or SC every 2–3 days. Testosterone cypionate: 2.2 mg/kg every 30 days or 200 mg IM every 30 days. (Bartges 2006a)

For estrus control:

- a) Testosterone enanthate or cypionate 0.5 mg/kg IM once every 5 days or methyltestosterone tablets 25 mg PO twice a week; this dose is for Greyhound-sized dogs. (Purswell 1999)

To reduce mammary gland enlargement seen in pseudopregnancy:

- a) Testosterone enanthate or cypionate 0.5–1 mg/kg IM once (Purswell 1999)

■ CATS:

For infertility or reduced libido: Using either testosterone cypionate or propionate:

- a) 0.1–1 mg every other day or every third day for 3–5 injections IM or SC. Not indicated for testis descent. (Verstegen 2000)

For testosterone-responsive urinary incontinence (may be used with phenylpropanolamine) in males:

- a) Testosterone propionate 5–10 mg IM as needed (Barsanti and Finco 1986), (Osborne, Kruger et al. 2000), (Bartges 2006a)

■ CATTLE:

To produce an estrus-detector (teaser) animal (cull cows, heifers, steers):

- a) Testosterone propionate 200 mg IM on day 1 and on days 4–9. On day 10, give 1 gram IM and attach a chinball marker and put with the breeding herd. To maintain the teaser give 1 gram booster every 10–14 days.

Alternatively, initially give testosterone enanthate 0.5 gram IM and 1.5 gram SC (divided in two separate locations). After 4 days attach chinball marker and put in with breeding herd. To maintain, give 0.5–0.75 gram SC every 10–14 days. (Wolfe 1986)

Monitoring

- Efficacy
- Adverse effects

Chemistry/Synonyms

The esterified compounds, testosterone cypionate, enanthate, and propionate are available commercially as injectable products. Testosterone cypionate occurs as an odorless to having a faint odor, creamy white or white, crystalline powder. It is insoluble in water, soluble in vegetable oils, and freely soluble in alcohol. Testosterone cypionate has a melting range of 98°–104°C. It may also be known as testosterone cyclopentylpropionate.

Testosterone enanthate occurs as an odorless to having a faint odor, creamy white or white, crystalline powder. It is soluble in vegetable oils, insoluble in water and melts between 34–39°C.

Testosterone propionate occurs as odorless, creamy white to white, crystals or crystalline powder. It is insoluble in water, freely soluble in alcohol and soluble in vegetable oils. Testosterone propionate melts between 118–123°C.

Testosterone Cypionate may also be known as: testosterone cyclopentylpropionate, testosterone cypionate, *Deposteron*®, *Depotrone*®, *Depo-Testosterone*®, *Duratest*®, *Scheinpharm Testone-Cyp*®, *T-Cypionate*®, *Testex*®, *Testiormina*®, *Testred*®, *Virilon*®, or *depAndro*®.

Testosterone Propionate may also be known as: NSC-9166, testosterone propionas, *Malogen in Oil*®, *Sostenon*®, *Sustanon*®, *Testanon 25*®, *Testex*®, *Testoviron*®, *Testoviron Depot*®, *Testovis*®, *Tesuren*®, or *Virormone*®.

Storage/Stability/Compatibility

The commercially available injectable preparations of testosterone cypionate, enanthate and propionate should be stored at room temperature; avoid freezing or exposing to temperatures greater than 40°C. If exposed to low temperature a precipitate may form, but should redissolve with shaking and rewarming. If a wet needle or syringe is used to draw up the parenteral solutions, cloudy solutions may result, but will not affect the drug's potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No known testosterone products (with the exception of combinations with estradiol as growth promotant implants) approved for use in veterinary species were located. Testosterone propionate (200 mg) is available in combination with estradiol benzoate (20 mg) as a growth promotant. Trade names include *Component E-H*® (VetLife); (OTC) and *Synovex-H*® (Fort Dodge); (OTC). For use in heifers weighing 400 or more pounds.

Testosterone propionate (200 mg) with estradiol benzoate (28 mg); *Synovex-Plus*® (Fort Dodge); (OTC); for steers.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Testosterone Cypionate (in oil) Injection: 100 mg/mL, and 200 mg/mL in 1 mL and 10 mL vials; *Depo-Testosterone*® (Pharmacia); generic (Watson); (Rx, C-III)

Testosterone Enanthate (in oil) Injection: 200 mg/mL in 5 mL multi-dose vials and 1 mL syringes; *Delatestyl*® (Savient); (Rx, C-III)

Testosterone Propionate Injection (in oil): 100 mg/mL in 10 mL vials; available generically; (Rx, C-III)

Testosterone Pellets: 75 mg (0.2 mg stearic acid, 2 mg polyvinylpyrrolidone) in 1 pellet/vials; *Testopel*® (Bartor Pharmacal); (Rx, C-III)

Testosterone Transdermal System: Release Rates: 5 and 2.5 mg/24 hour, total testosterone contents: 24.3 mg and 12.2 mg (respectively): *Androderm*® (Watson Pharma); (Rx, C-III)

Testosterone Gel: 1% testosterone in 2.5 g or 5 g packets of gel to deliver 25 mg or 50 mg testosterone and metered-dose pumps to deliver 75 g or 60 metered 1.25 g doses; *AndroGel*® 1% (Unimed Pharm.); *Testim*® (Auxilium Pharm.); (Rx, C-III)

Testosterone, Buccal System: 30 mg testosterone in blister packs; *Striant*® (Columbia); (Rx, C-III)

TETRACYCLINE HCL

(tet-ra-sye-kleen) Aquadrops®, Panmycin®

TETRACYCLINE ANTIBIOTIC

Prescriber Highlights

- Prototype tetracycline antibiotic; many bacteria are now resistant, but still may be very useful to treat mycoplasma, rickettsia, spirochetes, & Chlamydia
- Dosing frequency may be an issue for small animals
- Contraindications: Hypersensitivity
- Extreme Caution: Pregnancy
- Caution: Liver or renal insufficiency
- Adverse Effects: GI distress, staining of developing teeth & bones, superinfections, photosensitivity; long-term use may cause uroliths. CATS: Do not tolerate very well. HORSES: If stressed may break with diarrheas (oral use). RUMINANTS: High oral doses can cause ruminal microflora depression & ruminoreticular stasis; rapid IV of undiluted propylene glycol-based products can cause intravascular hemolysis & cardiodepressant effects; IM: local reactions, yellow staining & necrosis may be seen at the injection site

Uses/Indications

While tetracycline still is used as an antimicrobial, most small animal clinicians prefer doxycycline and large animal clinicians prefer oxytetracycline when a tetracycline is indicated to treat susceptible infections. The most common use of tetracycline HCl today is in combination with niacinamide for the treatment of certain immune-mediated skin conditions in dogs, such as pemphigus.

Pharmacology/Actions

Tetracyclines generally act as bacteriostatic antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococcus and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines include *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and tetani, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity include

Bordetella spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasturella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, *Enterobacter*, *Proteus* and *Pseudomonas aeruginosa* are resistant to the tetracyclines. While most strains of *Pseudomonas aeruginosa* show *in vitro* resistance to tetracyclines, those compounds attaining high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance and a tetracycline susceptibility disk is usually used for *in vitro* testing for oxytetracycline susceptibility.

Tetracyclines have antiinflammatory and immunomodulating effects. They can suppress antibody production and chemotaxis of neutrophils; inhibit lipases, collagenases, prostaglandin synthesis, and activation of complement component 3.

Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailabilities are approximately 60–80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration, tetracycline is erratically and poorly absorbed with serum levels usually lower than those attainable with oral therapy.

Tetracyclines as a class, are widely distributed to heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF, and therapeutic levels may not be achievable. While all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation and are distributed into milk. The volume of distribution of tetracycline is approximately 1.2–1.3 L/kg in small animals. The amount of plasma protein binding is about 20–67% for tetracycline. In cattle, the volume of distribution for oxytetracycline is between 1 and 2.5 L/kg. Milk to plasma ratios for oxytetracycline and tetracycline are 0.75 and 1.2–1.9, respectively.

Both oxytetracycline and tetracycline are eliminated unchanged primarily via glomerular filtration. Patients with impaired renal function can have prolonged elimination half-lives and accumulate the drug with repeated dosing. These drugs apparently are not metabolized, but are excreted into the GI tract via both biliary and nonbiliary routes and may become inactive after chelation with fecal materials. The elimination half-life of tetracycline is approximately 5–6 hours in dogs and cats.

Contraindications/Precautions/Warnings

Tetracycline is contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, tetracycline must be used cautiously; lower than normal dosages are recommended with enhanced monitoring of renal and hepatic function. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs if tetracyclines are administered to these patients. Monitoring of serum levels should be considered if long-term therapy is required.

Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause discoloration of bones and teeth to a yellow, brown, or gray color. High dosages or chronic administration may delay bone growth and healing.

Tetracyclines in high levels can exert an antianabolic effect that can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiodepressant effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well, and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs.

Horses that are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrheas after receiving tetracyclines (especially with oral administration).

Tetracycline therapy (especially long-term) may result in overgrowth of non-susceptible bacteria or fungi (superinfections).

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *D* (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Tetracyclines are excreted in milk, but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals.

Overdosage/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tetracyclines and may be of significance in veterinary patients:

- **ATOVAQUONE:** Tetracyclines have caused decreased atovaquone levels
- **BETA-LACTAM OR AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides; there is some controversy regarding the actual clinical significance of this interaction, however.
- **DIGOXIN:** Tetracyclines have increased the bioavailability of digoxin in a small percentage of human patients and caused digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products.
- **METHOXYFLURANE:** Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline not recommended
- **WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment

Laboratory Considerations

- Tetracyclines (not minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.
- Tetracyclines reportedly can cause false-positive **urine glucose results** if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest*®), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (*Clinistix*®, *Tes-Tape*®).

Doses

■ DOGS:

For discoid lupus erythematosus:

- a) For dogs weighing 10 kg or more: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing from 5–10 kg: 250 mg of each PO q8h. For dogs weighing <5 kg: 100 mg of each PO q8h. Improvement is usually noted within 6 weeks. (White 2000)
- b) Dogs weighing more than 10 kg: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing less than 10 kg: 250 mg of each PO q8h. May use in combination with corticosteroids and Vitamin E. If adverse effects become a problem, reduce dose of niacinamide first. May also try this regimen for pemphigus foliaceus or pemphigus erythematosus. (Campbell 1999)
- c) For various immune-mediated diseases (discoid lupus erythematosus, pemphigus erythematosus, pemphigus foliaceus, vasculitis, sterile pyelogramuloma, dermatomyositis and lupoid onychodystrophy: For dogs less than 10 kg: 250 mg each of niacinamide and tetracycline PO three times daily. For dogs larger than 10 kg: 500 mg each of niacinamide

and tetracycline PO three times daily. May substitute doxycycline for tetracycline at 5 mg/kg PO once a day. (Tapp 2002)

For susceptible infections:

- a) For UTI: 16 mg/kg PO q8h for 7–14 days;
For Rickettsiosis, Borreliosis: 22 mg/kg PO q8h for 14 days;
For systemic bacteremia, brucellosis: 22–50 mg/kg PO q8h for 28 days. (Greene, Hartmann et al. 2006)
- b) For Rocky Mountain Spotted Fever: 22 mg/kg q8h for 14–21 days (Sellon and Breitschwerdt 1995)
- c) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden and Papich 1995)
- d) 22–33 mg/kg PO q8h (Aronson and Aucoin 1989)
- e) For Lyme disease: 22 mg/kg PO q8h for 14 days (Breitschwerdt 2000)
- f) For small intestinal bacterial overgrowth: 5–10 mg/kg PO q8h for 28 days; has been effective for uncomplicated cases (Ludlow and Davenport 2000)
- g) For rickettsial diseases:
Ehrlichiosis: 22 mg/kg, PO three times daily for at least 14 days
Salmon poisoning: 22 mg/kg, PO three times daily for 10–14 days or 7 mg/kg IV three times daily
Rocky Mountain Spotted Fever: 22 mg/kg, PO three times daily for 10–14 days (Lissman 1988)

For facial tear staining:

- a) 5–10 mg/kg/day or 50 mg per dog per day. Results are variable. (Kern 1986)

For pleurodesis:

- a) Using capsules or aqueous solution; mix 20 mg/kg in 4 mL per kg of saline and infuse into pleural space (Morgan 1988)

■ CATS:

For susceptible infections:

- a) For soft tissue infections: 20 mg/kg PO q8h for 21 days;
For Hemotropic mycoplasmosis: 10–25 mg/kg PO q8–12h for 21 days;
For bacteremia, systemic infections: 7 mg/kg IV, IM q12h as long as necessary. (Greene, Hartmann et al. 2006)
- b) For rickettsial diseases: 16 mg/kg, PO three times daily for 21 days (Morgan 1988)
- c) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden and Papich 1995)
- d) 22–33 mg/kg PO q8h (Aronson and Aucoin 1989)

■ FERRETS:

For susceptible infections:

- a) 25 mg/kg PO 2–3 times daily (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 50–100 mg/kg PO q8–12h (Ivey and Morrissey 2000)
- b) Chinchillas: 50 mg/kg PO q8–12h (Hayes 2000)
- c) Chinchillas, Guinea Pigs, Rats: 20 mg/kg, PO q12h. Mice: 20 mg/kg, PO q12h or 50–60 mg/liter of drinking water. Hamsters: 30 mg/kg, PO q6h or 400 mg/liter, drinking water. Gerbils: 20 mg/kg, PO or IM q24h (Adamcak and Otten 2000)

■ CATTLE:

For susceptible infections in calves:

- 11 mg/kg orally (Howard 1986)
- 11 mg/kg, PO twice daily for up to 5 days (Label directions; *Polyotic*®—American Cyanamid)

■ SHEEP:

For susceptible infections:

- 11 mg/kg, PO twice daily for up to 5 days (Label directions; *Polyotic*®—American Cyanamid)

■ HORSES:

For susceptible infections:

- 5–7.5 mg/kg IV q12h (Brumbaugh 1987)

■ SWINE:

For susceptible infections:

- 22 mg/kg, PO for 3 to 5 days in drinking water (Label directions; *Polyotic*®—American Cyanamid)

■ BIRDS:

For susceptible infections:

- For treatment of psittacosis in conjunction with *LA-200*® (see oxytetracycline doses) and/or medicated pellets and/or *Keet Life*: Using 25 mg/mL oral suspension, mix 2 teaspoonsful to 1 cup of soft food.

For mild respiratory disease (especially flock treatment): Mix 1 teaspoonful of 10 g/6.4 oz. soluble powder per gallon of drinking water. Used as an adjunct for psittacosis with other tetracycline forms. Will not reach therapeutic levels by itself. Prepare fresh solution twice daily, as potency is rapidly lost. (McDonald 1989)

- Mix 1 teaspoonful of 10 g/6.4 oz. soluble powder per gallon of drinking water and administer for 5–10 days. Prepare fresh solution 2–3 times daily, as potency is rapidly lost.

For converting regimen to pelleted feeds administer oral suspension by gavage at 200–250 mg/kg once or twice daily until feeds are accepted. Is not an adequate therapy for long-term treatment of chlamydiosis (psittacosis) (Clubb 1986)

Monitoring

- Adverse effects
- Clinical efficacy
- Long-term use or in susceptible patients: periodic renal, hepatic, hematologic evaluations

Client Information

- Avoid giving this drug orally within 1–2 hours of feeding, giving milk or other dairy products
- If gastrointestinal upset occurs, giving with a small amount of food may help, but this may also reduce the amount of drug absorbed

Chemistry/Synonyms

An antibiotic obtained from *Streptomyces aureofaciens* or derived semisynthetically from oxytetracycline, tetracycline HCl occurs as a moderately hygroscopic, yellow, crystalline powder. About 100 mg/mL is soluble in water and 10 mg/mL soluble in alcohol. Tetracycline base has a solubility of about 0.4 mg per mL of water and 20 mg per mL of alcohol. Commercially available tetracycline HCl for IM injection also contains magnesium chloride, procaine HCl and ascorbic acid.

Tetracycline may also be known as: tetracyclini hydrochloridum; many trade names are available.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, tetracycline oral tablets and capsules should be stored in tight, light resistant containers at room temperature (15–30°C). The oral suspension and powder for injection should be stored at room temperature; avoid freezing the oral suspension.

After reconstituting the IM product, it may be stored at room temperature but should be used within 24 hours. After reconstituting the intravenous product with sterile water to a concentration of 50 mg/mL, the preparation is stable for 12 hours at room temperature. If further diluted in an appropriate IV fluid, use immediately.

Tetracycline HCl for intravenous injection is reportedly physically **compatible** with the following IV fluids and drugs: 0.9% sodium chloride, D5W, D5W in normal saline, Ringer's injection, lactated Ringer's injection, 10% invert sugar, dextrose-Ringer's and lactated Ringer's combinations, ascorbic acid, cimetidine HCl, colistimethate sodium, corticotropin, ephedrine sulfate, isoproterenol HCl, kanamycin sulfate, lidocaine HCl, metaraminol bitartrate, norepinephrine bitartrate, oxytetracycline HCl, oxytocin, potassium chloride, prednisolone sodium phosphate, procaine HCl, promazine HCl, and vitamin B complex with C.

Drugs that are reportedly physically **incompatible** with tetracycline, data conflicts, or compatibility is concentration/time dependent, include: amikacin sulfate, aminophylline, ampicillin sodium, amobarbital sodium, amphotericin B, calcium chloride/gluconate, carbenicillin disodium, cephalothin sodium, cephapirin sodium, chloramphenicol sodium succinate, dimenhydrinate, erythromycin gluceptate/lactobionate, heparin sodium, hydrocortisone sodium succinate, meperidine HCl, morphine sulfate, methicillin sodium, methohexital sodium, methylidopate HCl, oxacillin sodium, penicillin G potassium/sodium, phenobarbital sodium, sodium bicarbonate, thiopental sodium, and warfarin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are a variety of Tetracycline HCl Soluble Powder (as a water additive) products that are available in various concentrations and sizes. Usual concentrations are either 25 grams/lb or 324 grams/lb and these products may be available in several sizes; may be approved for use in swine, cattle, or poultry. Withdrawal time may vary depending on age of animal and product.

An oral combination product containing tetracycline, novobiocin and prednisone (*Delta Albaplex*®) is also available; see the novobiocin monograph for more information.

HUMAN-LABELED PRODUCTS:

Tetracycline HCl Capsules: 250 mg, and 500 mg; *Sumycin*® -250 & -500 (Par); generic; (Rx)

Tetracycline HCl Oral Suspension: 25 mg/mL in 473 mL; *Sumycin*® Syrup (Par); (Rx)

Theophylline—see Aminophylline

THIABENDAZOLE

(thye-a-ben-da-zole)

ANTHELMINTIC; ANTIFUNGAL

Prescriber Highlights

- ▶ Benzimidazole anthelmintic; has antifungal (dermatophytes) activity
- ▶ Contraindications: None noted
- ▶ Adverse Effects: **DOGS: Vomiting, diarrhea, hair loss, & lethargy.** Dachshunds may be particularly sensitive to thiabendazole. Toxic epidermal necrolysis (TEN) is rarely seen.
- ▶ Parasitic-resistance is an issue
- ▶ Many veterinary products no longer available

Uses/Indications

Thiabendazole has been used for the removal of the following parasites in dogs: ascarids (*Toxocara canis*, *T. leonina*), *Strongyloides stercoralis*, and *Filaroides*. It has been used systemically as an anti-fungal agent in the treatment of nasal aspergillosis and penicilliosis. Topical and otic use of thiabendazole for the treatment of various fungi is also commonly employed.

Thiabendazole is indicated (labeled) for the removal of the following parasites in cattle: *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Nematodirus* spp., *Cooperia* spp. and *Oesophagostomum radiatum*.

Thiabendazole is indicated (labeled) for the removal of the following parasites in sheep and goats: *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Nematodirus* spp., *Cooperia* spp., *Chabertia* spp., *Bunostomum* spp. and *Oesophagostomum* spp.

Thiabendazole is indicated (labeled) for the removal of the following parasites in horses: *Strongylus* spp., *craterstomum* spp., *Oesophagodontus* spp., *Posteristomum* spp., *Cyathostomum* spp., *Cylicocylus* spp., *Cylicostephanus* spp., *Oxyuris* spp., and *Parasacaris* spp.

Thiabendazole is indicated (labeled) for the removal or prevention of the following parasites in swine: large roundworms (*Ascaris suum*) (prevention), and in baby pigs infested with *Strongyloides ransomi*.

Although not approved, thiabendazole has been used in pet birds and llamas. See the Dosage section for more information.

In many geographic areas, significant thiabendazole resistance problems have developed and, for many parasites, other anthelmintics would be a better choice for treatment.

When used topically, thiabendazole has antidermatophytic properties.

Pharmacokinetics

Thiabendazole is relatively well absorbed (for a benzimidazole) and is distributed throughout body tissues. Peak levels occur in approximately 2–7 hours after dosing. Absorbed drug is rapidly metabolized in the liver by hydroxylation, glucuronidation and sulfate formation. Within 48 hours of dosing, 90% of the drug is excreted in the urine (as metabolites) and 5% in the feces. Less than 1% of the drug is excreted in the urine unchanged. Five days after a dose, the drug is virtually eliminated from the body.

Adverse Effects

At recommended doses, thiabendazole is usually well tolerated in approved species. In dogs, vomiting, diarrhea, hair loss, and lethargy are possible side effects, notably with high dose or long-term therapy. Dachshunds have been reported to be particularly sensitive to thiabendazole. Toxic epidermal necrolysis (TEN) has been reported in dogs receiving thiabendazole, but the incidence appears to be very rare.

Reproductive/Nursing Safety

Thiabendazole has not been demonstrated to be a teratogen and is considered generally safe to use during pregnancy. However, in high doses it has been implicated in causing toxemia in ewes. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

It is not known whether this drug is excreted in milk, but it is unlikely to be of clinical concern in nursing patients.

Overdosage/Toxicity

Thiabendazole has a safety margin of at least 20 times the recommended dose in horses. Doses of 800–1000 mg/kg are necessary to cause anorexia and depression in sheep. The minimum lethal dose is 700 mg/kg in cattle and 1200 mg/kg in sheep.

It is unlikely that a modest overdose would cause significant problems. If a massive overdose occurs, treat supportively and symptomatically. See the Adverse effects section for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiabendazole and may be of significance in veterinary patients:

- **THEOPHYLLINE:** Thiabendazole may compete with xanthines for metabolizing sites in the liver, thereby increasing xanthine blood levels

Doses

Note: There are no veterinary commercial products for systemic use currently being marketed in the USA.

■ DOGS:

As an antiparasitic agent:

- a) For treatment of *Strongyloides stercoralis*: 50–60 mg/kg PO (Todd, Paul, and DiPietro 1985)
- b) For treatment of *Filaroides* (now called *Oslerus*) infections: 35 mg/kg PO twice daily for 5 days, then 70 mg/kg PO twice daily for 21 days. Prednisone can also be given at 0.55 mg/kg, PO twice daily every other day (Ettinger, Kantrowitz et al. 2000)

As an antifungal agent:

- a) For treatment of nasal aspergillosis/penicilliosis infections: 30–70 mg/kg divided q12h PO in food for 20–45 days (Roudebush 1985)
- b) For the treatment of aspergillosis: 20 mg/kg PO, once a day or divided twice daily; (with or without ketoconazole: 20 mg/kg PO, once a day or divided twice daily). Maintenance therapy: 10–20 mg/kg PO once a day (Greene, O'Neal, and Barsanti 1984)

- c) For penicilliosis: With appropriate adjunctive surgical curettage and topical therapy, thiabendazole: 20 mg/kg/day PO for 4–6 weeks (Barsanti 1984)
- d) For aspergillosis: Administer 10 mg/kg as nasal flush. Dilute in 10–20 mL of water. Flush twice daily for 10 days. Orally: 20 mg/kg/day divided twice daily for 6 weeks (Morgan 1988)
- e) For treatment of nasal aspergillosis: 20 mg/kg divided q12h PO for 6–8 weeks. If anorexia or nausea develops, may withdraw drug and then gradually reintroduce to the full dosage. Administer with food to enhance absorption and reduce anorexia. May be effective in 40–50% of dogs treated. (Sharp 1989)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: For pinworms: 50–100 mg/kg PO for 5 days or 50 mg/kg PO, repeat in 3 weeks (Ivey and Morrissey 2000)
- b) Mice, Rats, Gerbils, Hamsters, Guinea pigs: 100 mg/kg, PO for 5 days. Chinchillas: 50–100 mg/kg PO for 5 days (Adamcak and Otten 2000)
- c) For pinworms in Mice, Rats, Hamsters, Gerbils and Rabbits: 50 mg/kg, PO once (Burke 1999)

■ CATTLE:

For susceptible parasites:

- a) 66 mg/kg PO; 110 mg/kg PO for Cooperia and severe infections of other susceptible nematodes. Retreat treatment in 2–3 weeks if indicated (Paul 1986), (Roberson 1988b)
- b) 50–100 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ HORSES:

For susceptible parasites:

- a) 44 mg/kg, PO (Robinson 1987)
- b) 44 mg/kg; 88 mg/kg for ascarids (Roberson 1988b)
- c) 50–100 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ SWINE:

For susceptible parasites:

- a) For baby pigs with *Strongyloides ransomi*: 62–83 mg/kg PO, retreat in 5–7 days if necessary. To prevent Ascaris suum: Feed at 0.05–0.1% per ton of feed for 2 weeks, then 0.005–0.02% per ton for 8–14 weeks (Paul 1986)
- b) 75 mg/kg, PO (Roberson 1988b)
- c) 50 mg/kg, PO (Brander, Pugh, and Bywater 1982)

■ SHEEP & GOATS:

For susceptible parasites:

- a) 44 mg/kg PO; 66 mg/kg PO for severe infections in goats (Paul 1986), (Roberson 1988b)
- b) 50–100 mg/kg PO (sheep) (Brander, Pugh, and Bywater 1982)

■ LLAMAS:

For susceptible parasites:

- a) 50–100 mg/kg PO for 1–3 days. Use higher dosage rate over several days when animal is severely parasitized. (Cheney and Allen 1989)
- b) 66 mg/kg PO (Fowler 1989)

■ BIRDS:

For susceptible parasites:

- a) For ascarids: 250–500 mg/kg PO once. Repeat in 10–14 days. For Syngamus trachea: 100 mg/kg, PO once a day for 7–10 days (Clubb 1986)

- b) For ascarids, Capillaria, gapeworms:

Chickens, pheasants, turkeys, and pigeons: Mix 0.5% in feed for 10 days or administer orally at 44 mg/kg as a single dose.

Psittacines: 44 mg/kg PO; do not exceed this dose.

Falcons: 100 mg/kg PO as a single dose (Stunkard 1984)

- c) For thorny headed worms in waterfowl and raptors: 250 mg/lb (Stunkard 1984)

Client Information

- Shake suspension well before using.
- Follow veterinarian's or label's directions carefully.

Chemistry/Synonyms

The prototypic benzimidazole, thiabendazole occurs as an odorless or nearly odorless, tasteless, white to practically white powder. It has a melting range of 296°–303°C and a pK_a of 4.7. Thiabendazole is practically insoluble in water and slightly soluble in alcohol.

Thiabendazole may also be known as: E233, MK-360, tiabendazolium, tiabendazole, *Benzol*®, *Eprofil*®, *Foldan*®, *Folderm*®, *Mintezol*®, *Thiaben*®, *Thianax*®, *Tiabendol*®, *Tiabiose*®, *Tiaplex*®, *Triasox*®, or *Tutiverm*®.

Storage/Stability

Thiabendazole tablets, boluses and oral suspension should be stored in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the USA for systemic use. Thiabendazole is an active ingredient in the topical/otic preparation *Tresaderm*®.

Food residue tolerances: 0.1 ppm in uncooked meat of cattle, pheasants, swine, sheep and goats; 0.05 ppm in milk.

HUMAN-LABELED PRODUCTS:

Thiabendazole Chewable Scored Tablets: 500 mg; *Mintezol*® (Merck); (Rx)

Thiabendazole Oral Suspension: 100 mg/mL in 120 mL; *Mintezol*® (Merck); (Rx)

Thiacetarsamide (no longer available)—See Melarsomine

THIAMINE HCL VITAMIN B₁

(*thye-a-min*)

NUTRITIONAL; B VITAMIN

Prescriber Highlights

- A "B" vitamin used for treatment or prevention of thiamine deficiency. May be useful for adjunctive treatment of lead poisoning & ethylene glycol toxicity
- Contraindications: hypersensitivity to it
- Adverse Effects: hypersensitivity reactions (rarely); tenderness, or muscle soreness after IM injection
- Drug Interactions; lab interactions

Uses/Indications

Thiamine is indicated in the treatment or prevention of thiamine deficiency states. Clinical signs of thiamine deficiency may be manifested as gastrointestinal (anorexia, salivation), neuromuscular/CNS signs (ataxia, seizures, loss of reflexes), or cardiac effects (brady- or tachyarrhythmias). Deficiency states may be secondary to either a lack of thiamine in the diet or the presence of thiamine destroying compounds in the diet (e.g., bracken fern, raw fish, amprolium, thiaminase-producing bacteria in ruminants).

Thiamine has also been used in the adjunctive treatment of lead poisoning and ethylene glycol toxicity (to facilitate the conversion of glyoxylate to nontoxic metabolites).

Pharmacology/Actions

Thiamine combines with adenosine triphosphate (ATP) to form a compound (thiamine diphosphate/thiamine pyrophosphate) that is employed for carbohydrate metabolism, but does not effect blood glucose concentrations.

Absence of thiamine results in decreased transketolase activity in red blood cells and increased pyruvic acid blood concentrations. Without thiamine triphosphate, pyruvic acid is not converted into acetyl-CoA; diminished NADH results with anaerobic glycolysis producing lactic acid. Lactic acid production is further increased secondary to pyruvic acid conversion; lactic acidosis may occur.

Pharmacokinetics

Thiamine is absorbed from the GI tract and is metabolized by the liver. Elimination is renal, the majority of the drug is eliminated as metabolites.

Contraindications/Precautions/Warnings

Thiamine injection is contraindicated in animals hypersensitive to it or to any component of it.

Adverse Effects

Hypersensitivity reactions have occurred after injecting this agent. Some tenderness or muscle soreness may result after IM injection.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **A** for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) If used in doses greater than the RDA, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk, but it should not be of clinical concern.

Overdosage/Acute Toxicity

Very large doses of thiamine in laboratory animals have been associated with neuromuscular or ganglionic blockade, but the clinical significance is unknown. Hypotension and respiratory depression may also occur with massive doses. A lethal dose of 350 mg/kg has been reported. Generally, no treatment should be required with most overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiamine and may be of significance in veterinary patients:

- **NEUROMUSCULAR BLOCKING AGENTS:** Thiamine may enhance the activity of neuromuscular blocking agents; clinical significance is unknown

Laboratory Considerations

- Thiamine may cause false-positive **serum uric acid** results when using the phosphotungstate method of determination or urobilinogen urine spot tests using Ehrlich's reagent
- The Schack and Wexler method of determining **theophylline concentrations** may be interfered with by large doses of thiamine

Doses

■ DOGS:

For thiamine deficiency:

- a) 5–50 mg IM, SC, or IV (depending on formulation) (Phillips 1988b)
- b) 1–2 mg IM (Greene and Braund 1989)
- c) 2 mg/kg, PO once daily (Davis 1985)
- d) 100–250 mg SC twice daily for several days until regression of symptoms with complete recovery (Hoskins 1988)

For adjunctive treatment for ethylene glycol toxicity:

- a) 100 mg/day PO (Morgan 1988)

■ CATS:

For thiamine deficiency:

- a) 100–250 mg parenterally twice a day (experimentally, as little as 1 mg is effective) (Armstrong and Hand 1989)
- b) 1–2 mg IM (Greene and Braund 1989)
- c) 4 mg/kg, PO once daily (Davis 1985)
- d) 100–250 mg SC twice daily for several days until regression of symptoms with complete recovery (Hoskins 1988)
- e) 10–20 mg/kg IM or SC two to three times daily until signs abate, then 10 mg/kg PO once daily for 21 days (Morgan 1988)

■ CATTLE:

For thiamine deficiency:

- a) For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)
- b) 10–20 mg/kg IM or SC 3 times daily; if giving IV dilute in isotonic saline or isotonic dextrose. (Walz 2006a)
- c) 10 mg/kg up to 4 times a day; first dose may be given via slow IV and subsequent doses IM. Less severely affected animals may respond to lower or less frequent dosing. Severely affected animals may benefit from corticosteroids (dexamethasone 1–2 mg/kg) and mannitol (1 g/kg in a 20% solution IV through a filtered IV set). (Cebra 2005)

For adjunctive therapy of lead poisoning:

- a) 2 mg/kg IM (at same time as CaEDTA therapy); total daily dose 8 mg/kg (Brattan and Kowalczyk 1989)

■ HORSES:

For thiamine deficiency:

- a) 0.5–5 mg/kg IV, IM or PO (Robinson 1987)
- b) 100–1000 mg IM, SC, or IV (depending on formulation) (Phillips 1988b)

For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):

- a) Foals: 1 gram in one liter of fluids IV once a day (Slovic 2003b)

■ SWINE:

For thiamine deficiency:

- a) 5–100 mg IM, SC, or IV (depending on formulation) (Phillips 1988b)

■ SHEEP & GOATS:

For thiamine deficiency:

- For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)
- Sheep: 20–200 mg IM, SC, or IV (depending on formulation) (Phillips 1988b)

Monitoring

- Efficacy

Client Information

- Epidemiologic investigation as to the cause of thiamine deficiency (diet, plants, raw fish, etc.) should be performed with necessary changes made to prevent recurrence

Chemistry/Synonyms

A water-soluble “B” vitamin, thiamine HCl occurs as bitter-tasting, white, small hygroscopic crystals, or crystalline powder that has a characteristic yeast-like odor. Thiamine HCl is freely soluble in water, slightly soluble in alcohol and has pK_a s of 4.8 and 9.0. The commercially available injection has a pH of 2.5–4.5.

Thiamine HCl may also be known as: aneurine hydrochloride, thiamin hydrochloride, thiamine chloride, thiamini hydrochloridum, thiaminii chloridum, vitamin B-1; many trade names available.

Storage/Stability/Compatibility

Thiamine HCl for injection should be protected from light and stored at temperatures less than 40°C and preferably between 15–30°C; avoid freezing.

Thiamine HCl is unstable in alkaline or neutral solutions or with oxidizing or reducing agents. It is most stable at a pH of 2.

Thiamine HCl is reportedly physically **compatible** with all commonly used intravenous replacement fluids. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Thiamine HCl for Injection: 200 mg/mL in 100 mL and 250 mL vials; *Amtech® Thiamine Hydrochloride Injection* (Phoenix Scientific), *Am-Vet® Thiamine Hydrochloride 200 Mg*, (Neogen), generic, (Vet Tek, IVX, Vedco), *Vita-Jec® Thiamine HCl* (RXV); (Rx)

Thiamine HCl for Injection: 500 mg/mL in 100 mL vials; *Am-Vet® Thiamine Hydrochloride 500 mg* (Neogen), generic, (Butler, IVX, Vedco); (Rx). Labeled for use in horses, dogs and cats.

Thiamine HCl Dietary Supplement: 8,200 mg/lb.; *Horse Care Durvit B-1 Crumbles®* (Durvet); (OTC), Labeled for use in horses.

Thiamine HCl Supplement: 500 mg/oz in 1.5 lb, 4 lb and 20 lb containers; *Thia-Dex®* (Neogen), *Vitamin B-1 Powder®* (AHC); (OTC). Labeled for use in dogs & horses.

There are several B-complex vitamin preparations available that may also have thiamine included.

HUMAN-LABELED PRODUCTS:

Thiamine Tablets: 50 mg, 100 mg, and 250 mg; generic; (OTC)

Thiamine Enteric Coated Tablets: 20 mg; *Thiamilate®* (Tyson); (OTC)

Thiamine HCl Injection: 100 mg/mL in 1 mL, 2 mL multi-dose vials and 2 mL *Tubex*; generic; (Rx)

THIOGUANINE

(thye-oh-*gwah*-neen)

ANTINEOPLASTIC

Prescriber Highlights

- Oral purine analog antineoplastic that may be useful as adjunctive treatment for acute lymphocytic or granulocytic leukemia in dogs or cats
- Contraindications: Hypersensitivity to thioguanine
- Caution: Hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or history of urate urinary stones
- Potentially mutagenic & teratogenic; use milk replacer if nursing
- Adverse Effects: GI effects, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, & dermatologic reactions
- Cats may be more susceptible than dogs to adverse effects
- Low therapeutic index; monitoring mandatory

Uses/Indications

Thioguanine may be useful as adjunctive therapy for acute lymphocytic or granulocytic leukemia in dogs or cats.

Pharmacology/Actions

Intracellularly, thioguanine is converted to ribonucleotides that cause the synthesis and utilization of purine nucleotides to be blocked. The drug's cytotoxic effects are believed to occur when these substituted nucleotides are inserted into RNA and DNA. Thioguanine has limited immunosuppressive activity. Extensive cross-resistance usually occurs between thioguanine and mercaptopurine.

Pharmacokinetics

Thioguanine is administered orally, but absorption is variable. In humans, only about 30% of a dose is absorbed. Thioguanine is distributed into the DNA and RNA of bone marrow, but several doses may be necessary for this to occur. It does not apparently enter the CNS, but does cross the placenta. It is unknown whether it enters maternal milk.

Thioguanine is rapidly metabolized primarily in the liver to a methylate derivative that is less active (and toxic) than the parent compound. This and other metabolites are eliminated in the urine.

Contraindications/Precautions/Warnings

Thioguanine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thioguanine has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

Adverse Effects

At usual doses, GI effects (nausea, anorexia, vomiting, diarrhea) may occur in small animals. However, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, and dermatologic reactions are potentially possible. Cats may be particularly susceptible to the hematologic effects of thioguanine.

Reproductive/Nursing Safety

Thioguanine is potentially mutagenic and teratogenic and not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although it is unknown whether thioguanine enters milk, use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity

Toxicity may be acute (GI effects) or delayed (bone marrow depression, hepatotoxicity, gastroenteritis). It is suggested to use standard protocols to empty the GI tract if ingestion was recent and treat supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thioguanine and may be of significance in veterinary patients:

- **HEPATOTOXIC DRUGS** (e.g., **halothane**, **ketoconazole**, **valproic acid**, **phenobarbital**, **primidone**, etc.): Thioguanine should be used cautiously with other drugs that can cause hepatotoxicity
- **IMMUNOSUPPRESSIVE DRUGS** (e.g., **azathioprine**, **cyclophosphamide**, **corticosteroids**): Use with other immunosuppressant drugs may increase the risk of infection
- **MYELOSUPPRESSIVE DRUGS** (e.g., **chloramphenicol**, **flucytosine**, **amphotericin B**, or **colchicine**): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- **VACCINES, LIVE**: Live virus vaccines should be used with caution during therapy, if at all

Laboratory Considerations

- Thioguanine may increase serum **uric acid** levels in some patients

Doses

■ DOGS:

- a) For acute lymphocytic and granulocytic leukemia: 40 mg/m² PO once daily (q24 hours) for 4–5 days, then every 3rd day thereafter (Jacobs, Lumsden et al. 1992)
- b) As part of protocols for treatment of acute myelogenous leukemias: Protocol 1: Cytarabine 100 mg/m² SC daily for 2–6 days; Thioguanine 50 mg/m² PO q24–48h. Protocol 2: Cytarabine 100 mg/m² SC daily for 2–6 days; Thioguanine 50 mg/m² PO q24–48h; Doxorubicin 10 mg/m² IV once a week (Couto 2003)

■ CATS:

- a) For acute lymphocytic and granulocytic leukemia: 25 mg/m² PO once daily (q24 hours) for 1–5 days, then every 30 days thereafter as necessary (Jacobs, Lumsden et al. 1992)

Monitoring

- Hemograms (including platelets) should be monitored closely; initially every 1–2 weeks and every 1–2 months once on maintenance therapy. It is recommended by some clinicians that if the WBC count drops to between 5,000–7,000 cells/mm³ the dose be reduced by 25%. If WBC count drops below 5,000 cells/mm³ treatment should be discontinued until leukopenia resolves
- Liver function tests; serum amylase, if indicated
- Efficacy

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality.
- Clients should contact veterinarian if the animal exhibits clinical signs of abnormal bleeding, bruising, anorexia, vomiting, jaundice, or infection.
- Although, no special precautions are necessary with handling intact tablets, it is recommended to wash hands after administering the drug.

Chemistry/Synonyms

A purine analog antineoplastic agent, thioguanine occurs as a pale yellow, odorless or practically odorless, crystalline powder. It is insoluble in water or alcohol.

Thioguanine may also be known as: NSC-752, 6-thioguanine, TG, 6-TG, 2-Amino-6-mercaptopurine, WR-1141, *Lanvis*®, *Tabloid*®, or *Tioguanina*®.

Storage/Stability

Store tablets in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Thioguanine Tablets: 40 mg; *Tabloid*® (GlaxoSmithKline); (Rx)

THIOPENTAL SODIUM

(thye-oh-*pen*-tal) Pentothal®

ULTRA-SHORT ACTING THIOBARBITURATE

Prescriber Highlights

- ▶ Ultra-short acting thiobarbiturate used for anesthesia induction or anesthesia for very short procedures
- ▶ **Contraindications:** Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, & conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). Greyhounds (& other sight hounds) metabolize thiobarbiturates much more slowly than other breeds; consider using methohexital instead. **HORSES:** preexisting leukopenia; thiopental alone may cause excessive ataxia & excitement
- ▶ **Avoid:** Extravasation, intra-carotid or intra-arterial injections, & use of concentrations of less than 2% in sterile water. Too rapid IV administration can cause significant vascular dilatation & hypoglycemia
- ▶ **Adverse Effects:** **DOGS:** Ventricular bigeminy **CATS:** Apnea after injection, mild arterial hypotension. **HORSES:** Excitement & severe ataxia (if used alone); transient leukopenias, hyperglycemia, apnea, moderate tachycardia, mild respiratory acidosis
- ▶ Severe CNS toxicity & tissue damage has occurred in horses receiving intra-carotid injections of thiobarbiturates
- ▶ C-III controlled substance

Uses/Indications

Because of its rapid action and short duration, in young, healthy animals, thiopental is excellent induction agent (rapid IV bolus) for general anesthesia with other anesthetics or as the sole anesthetic agent for very short procedures. In sick or debilitated animals, thiopental may be used in a more cautious manner (IV, slowly to effect).

Pharmacology/Actions

Because of their high lipid solubility, thiobarbiturates rapidly enter the CNS and produce profound hypnosis and anesthesia. They are also known as ultrashort-acting barbiturates. See the monograph: Barbiturates, Pharmacology of, for additional information.

Pharmacokinetics

Following IV injection of therapeutic doses, hypnosis and anesthesia occur within one minute. The drug rapidly enters the CNS and then redistributes to muscle and adipose tissue in the body. The short duration of action (10–30 minutes) after intravenous dosing of thiopental is due less to rapid metabolism than to this redistribution out of the CNS and into muscle and fat stores. Greyhounds and other sight hounds may exhibit longer recovery times than other breeds. This may be due to these breeds low body fat levels or differences in the metabolic handling of the thiobarbiturates. Although anesthesia is short, recovery periods may require several hours.

Thiopental is metabolized by the hepatic microsomal system and several metabolites have been isolated. The elimination half-life in dogs has been reported as being approximately 7 hours and in sheep, 3–4 hours. Very little of the drug is excreted unchanged in the urine (0.3% in humans), so dosage adjustments are not necessary in patients with chronic renal failure.

Contraindications/Precautions/Warnings

The following are considered **absolute contraindications** to the use of thiopental: absence of suitable veins for IV administration, history of hypersensitivity reactions to the barbiturates, and status asthmaticus. **Relative contraindications** include: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). These relative contraindications do not preclude the use of thiopental, but dosage adjustments must be considered and the drug must be given slowly and cautiously.

Because greyhounds (and other sight hounds) metabolize thiobarbiturates much more slowly than methohexital, many clinicians recommend using methohexital instead. In horses, thiopental should not be used if the patient has preexisting leukopenia. Some clinicians feel that thiopental should not be used alone in the horse as it may cause excessive ataxia and excitement.

Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. Extravasation and intra-arterial injections should be avoided because of the high alkalinity of the solution. Severe CNS toxicity and tissue damage has occurred in horses receiving intra-carotid injections of thiobarbiturates.

Adverse Effects

In dogs, thiopental has an approximate arrhythmogenic incidence of 40%. Ventricular bigeminy is the most common arrhythmia seen; it is usually transient and generally responds to additional oxygen. Administration of catecholamines may augment the arrhythmogenic effects of the thiobarbiturates, while lidocaine may inhibit it. Cardiac output may also be reduced, but is probably only clinically significant in patients experiencing heart failure. Dose-related apnea and hypotension may be noted.

Cats are susceptible to developing apnea after injection and may develop a mild arterial hypotension.

Horses can exhibit clinical signs of excitement and severe ataxia during the recovery period if the drug is used alone. Horses can develop transient leukopenias and hyperglycemia after administration. A period of apnea and moderate tachycardia and a mild respiratory acidosis may also develop after dosing.

Too rapid IV administration can cause significant vascular dilatation and hypoglycemia. Repeated administration of thiopental is not advised as recovery times can become significantly prolonged. Parasympathetic side effects (e.g., salivation, bradycardia) may be managed with the use of anticholinergic agents (atropine, glycopyrrolate).

Prolonged recoveries may occur when repeated dosages of thiopental are administered.

Thiopental's high pH (10–11) can cause significant tissue irritation and necrosis if administered perivascularly; administration through an IV catheter is advised.

Reproductive/Nursing Safety

Thiopental readily crosses the placental barrier and should be used with caution during pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and*

no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Small amounts of thiopental may appear in milk following administration of large doses, but is unlikely to be of clinical significance in nursing animals.

Overdosage/Acute Toxicity

Treatment of thiobarbiturate overdosage consists of supporting respirations (O₂, mechanical ventilation) and giving cardiovascular support (do not use catecholamines, e.g., epinephrine, etc.).

Drug Interactions

A fatal interaction has been reported in a dog receiving the proprietary product, **Diathal**® (no longer marketed; contained procaine penicillin G, dihydrostreptomycin sulfate, diphemanil methylsulfate, and chlorpheniramine) and the related compound thiamylal.

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiopental and may be of significance in veterinary patients:

- **CLONIDINE:** IV clonidine prior to induction may reduce thiopental dosage requirements by up to 37%
- **CNS DEPRESSANTS, OTHER:** May enhance respiratory and CNS depressant effects
- **DIAZOXIDE:** Potential for hypotension
- **EPINEPHRINE, NOREPINEPHRINE:** The ventricular fibrillatory effects of epinephrine and norepinephrine may be potentiated when used with thiobarbiturates and halothane
- **METOCLOPRAMIDE:** Given prior to induction may reduce thiopental dosage requirements
- **MIDAZOLAM:** May potentiate hypnotic effects
- **OPIATES:** Given prior to induction may reduce thiopental dosage requirements
- **PHENOTHIAZINES:** May potentiate thiopental effects; hypotension possible
- **PROBENECID:** May displace thiopental from plasma proteins
- **SULFONAMIDES:** Thiopental and sulfas may displace one another from plasma proteins

Doses

Note: Atropine sulfate (or glycopyrrolate) is often administered prior to thiobarbiturate anesthesia to prevent parasympathetic side effects; however, some clinicians question whether routine administration of anticholinergic agents is necessary.

Thiobarbiturates are administered strictly to effect; *doses are guidelines only.*

■ DOGS:

- a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; **Pentothal**®—Ceva Laboratories)
- b) 15–17 mg/kg IV for brief (7–10 minutes) anesthesia; 18–22 mg/kg IV for moderate (10–15 minutes) duration; 22–29 mg/kg IV for longer (15–25 minutes) duration (Booth 1988a)
- c) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)
- d) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005a)

■ CATS:

- a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; **Pentothal**®—Ceva Laboratories)
- b) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)
- c) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005a)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 15–30 mg/kg IV to effect (Ivey and Morrissey 2000)
- b) For chemical restraint: Mice: 50 mg/kg IP; Rats: 40 mg/kg IP; Hamsters/Gerbils: 30–40 mg/kg IP; Guinea pig: 15–30 mg/kg IV; Rabbits: 15–30 mg/kg IV (Burke 1999)

■ CATTLE:

- a) 8.14–15.4 mg/kg IV;
For unweaned calves from which food has been withheld for 6–12 hours: no more than 6.6 mg/kg IV for deep surgical anesthesia (**Pentothal**® package insert; Ceva Laboratories)
- b) For calves under 2 weeks of age: 15–22 mg/kg IV slowly until complete muscular relaxation takes place, duration of anesthesia usually lasts 10–12 minutes (Booth 1988a)
- c) 5.5 mg/kg IV after sedation and administration with guaifenesin; or 8.8–11 mg/kg IV after tranquilization (Mandsager 1988)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

- a) With preanesthetic tranquilization: 6–12 mg/kg IV (an average of 8.25 mg/kg is recommended); Without preanesthetic tranquilization: 8.8–15.4 mg/kg IV (an average horse: 9.9–11 mg/kg IV) (Package insert; **Pentothal**®—Ceva Laboratories)
- b) One gram of thiopental per 90 kg body weight as a 10% solution given evenly over 20 seconds 15 minutes after premedication with either 0.22 mg/kg IV xylazine or 0.05 mg/kg IV acepromazine (Booth 1988a)
- c) 5.5 mg/kg IV after sedation and administration with guaifenesin; or 8.8–11 mg/kg IV after tranquilization (Mandsager 1988)

■ SWINE:

- a) 5.5–11 mg/kg IV (Package insert; **Pentothal**®—Ceva Laboratories)
- b) For swine weighing 5–50 kg: 10–11 mg/kg IV (Booth 1988a)

■ SHEEP:

- 9.9–15 mg/kg IV depending on depth of anesthesia required (Package insert; **Pentothal**®—Ceva Laboratories)

■ GOATS:

- a) 20–22 mg/kg IV after atropine (0.7 mg/kg) IM (Booth 1988a)

Monitoring

- Level of hypnosis/anesthesia
- Respiratory status; cardiac status (rate/rhythm/blood pressure)

Client Information

This drug should only be used by professionals familiar with its effects in a setting where adequate respiratory support can be performed.

Chemistry/Synonyms

A thiobarbiturate, thiopental occurs as a bitter tasting, white to off-white, crystalline powder or a yellow-white hygroscopic powder. It is soluble in water (1 gram in 1.5 mL) and alcohol. Thiopental has a pK_a of 7.6 and is a weak organic acid.

Thiopental sodium may also be known as: thiopentone sodium, natrium isopentylaehtylthiobarbituricum, penthiobarbital sodique, thiomebumnatrium cum natrii carbonate, thiopentalum natrium, thiopentobarbitalum solubile, tiopentol sodico, *Anesthal*®, *Bensulf*®, *Farmotal*®, *Hipnopento*®, *Inductal*®, *Intraval*®, *Nesdonal*®, *Pensodital*®, *Pentothal*®, *Sandothal*®, *Sodipental*®, *Thionembutal*®, *Thiopentax*®, *Tiobarbital*®, or *Trapanal*®.

Storage/Stability/Compatibility

When stored in the dry form, thiopental sodium is stable indefinitely. Thiopental should be diluted with only sterile water for injection, sodium chloride injection, or D5W. Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. After reconstitution, solutions are stable for 3 days at room temperature and 7 days if refrigerated; however, as no preservative is present, it is recommended it be used within 24 hours after reconstitution. After 48 hours, the solution has been reported to attack the glass bottle in which it is stored. Thiopental may also adsorb to plastic IV tubing and bags. Do not administer any solution that has a visible precipitate.

Preparation of Solution for Administration: Use only sterile water for injection, normal saline, or D5W to dilute. A 5 gram vial diluted with 100 mL will yield a 5% solution and diluted with 200 mL will yield a 2.5% solution. Discard reconstituted solutions after 24 hours.

The following agents have been reported to be physically **compatible** when mixed with thiopental: aminophylline, chloramphenicol sodium succinate, hyaluronidase, hydrocortisone sodium succinate, neostigmine methylsulfate, oxytocin, pentobarbital sodium, phenobarbital sodium, potassium chloride, scopolamine HBr, sodium iodide, and tubocurarine chloride (recommendations conflict with regard to tubocurarine; some clinicians recommend not mixing with thiopental).

The following agents have been reported to be physically **incompatible** when mixed with thiopental: Ringer's injection, Ringer's injection lactate, amikacin sulfate, atropine sulfate, benzquinamide, cephalirin sodium, chlorpromazine, codeine phosphate, dimenhydrinate, diphenhydramine, ephedrine sulfate, glycopyrrolate, hydromorphone, insulin (regular), levorphanol bitartrate, mep-eridine, metaraminol, morphine sulfate, norepinephrine bitartrate, penicillin G potassium, prochlorperazine edisylate, promazine HCl, promethazine HCl, succinylcholine chloride, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None presently being marketed in USA.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Thiopental Sodium Powder for Injection: 2% (20 mg/mL) in 1 g, 2.5 g and 5 g kits; 400 mg *Min-I-Mix* vials with *Min-I-Mix* injector; *Ready-to-Mix* and *Ready-to-Mix LifeShield* syringes; 2.5% (25 mg/mL) in 250 mg and 500 mg *Min-I-Mix* vials; 500 mg, 1 g, 2.5 g, 5 g and 10 g kits, 250 mg and 500 mg *Ready-to-Mix* syringes and *Ready-to-Mix LifeShield* syringes; *Pentothal*® (Abbott); generic; (Rx, C-III)

THIOTEPA

(thye-oh-tep-ah)

ANTINEOPLASTIC**Prescriber Highlights**

- Antineoplastic used systemically for carcinomas, intracavitary for neoplastic effusions, & intravesical for transitional carcinomas; rarely used in small animal oncology
- Contraindications: Hypersensitivity to thiotepa; Caution: Hepatic dysfunction, bone marrow depression, infection, tumor cell infiltration of bone marrow, renal dysfunction, or history of urate urinary stones
- Adverse Effects: Leukopenia most likely adverse effect; other hematopoietic toxicity (thrombocytopenia, anemia, pancytopenia), GI toxicity possible. Intracavitary or intravesical instillation can also cause hematologic toxicity.
- Potentially teratogenic; use milk replacer if patient nursing
- Monitor diligently

Uses/Indications

Veterinary indications for thiotepa include: systemic use for adjunctive therapy against carcinomas, and intracavitary use for neoplastic effusions. In dogs with transitional cell bladder carcinoma, intravesical instillation of thiotepa had significantly less efficacy (mean survival time = 57 days) when compared to a systemic doxorubicin/cyclophosphamide protocol (mean survival time = 259 days).

Pharmacology/Actions

Thiotepa is an alkylating agent, thereby interfering with DNA replication and RNA transcription. It is cell cycle non-specific. Thiotepa has some immunosuppressive activity. When given via the intracavitary route, thiotepa is thought to control malignant effusions by a direct antineoplastic effect.

Pharmacokinetics

Thiotepa is poorly absorbed from the GI tract. Systemic absorption is variable from the pleural cavity, bladder, and after IM injection. Some studies in humans have shown that absorption from bladder mucosa ranges from 10–100% of an administered dose. Distribution characteristics are not well described; it is unknown if the drug enters maternal milk. Thiotepa is extensively metabolized and then excreted in the urine.

Contraindications/Precautions/Warnings

Thiotepa is contraindicated in patients hypersensitive to it. The drug should be used cautiously (weigh risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, tumor cell infiltration of bone marrow, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thiotepa has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

Adverse Effects

When used systemically, leukopenia is the most likely adverse effect seen in small animals. Other hematopoietic toxicity (thrombocytopenia, anemia, pancytopenia) may be noted. Intracavitary or intravesical instillation of thiotepa may cause hematologic toxicity. GI toxicity (vomiting, diarrhea, stomatitis, intestinal ulceration) may

be noted and human patients have reported dizziness and headache as well.

Reproductive/Nursing Safety

Thiotepa is potentially mutagenic and teratogenic and is not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although it is unknown whether thiotepa enters milk, use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity

There is no specific antidote for thiotepa overdose. Supportive therapy, including transfusions of appropriate blood products, may be beneficial for treatment of hematologic toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiotepa and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSIVE DRUGS** (e.g., **azathioprine**, **cyclophosphamide**, **corticosteroids**): Use with other immunosuppressant drugs may increase the risk of infection
- **MYELOSUPPRESSIVE DRUGS** (e.g., **chloramphenicol**, **flucytosine**, **amphotericin B**, or **colchicine**): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- **VACCINES, LIVE**: Live virus vaccines should be used with caution during therapy, if at all

Laboratory Considerations

- Thiotepa may increase serum **uric acid** levels in some patients

Doses

- **DOGS**:
 - a) For intracavitary use neoplastic effusions or systemically for adjunctive therapy of carcinomas: 0.2–0.5 mg/m² intracavitary; IV. (Jacobs, Lumsden et al. 1992)

Monitoring

- Efficacy
- CBC with platelets

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality
- Clients should contact veterinarian should the animal exhibit clinical signs of abnormal bleeding, bruising, anorexia, vomiting, jaundice, or infection

Chemistry/Synonyms

An ethylene derivative alkylating agent antineoplastic, thiotepa occurs as fine, white crystalline flakes. The drug has a faint odor and is freely soluble in water or alcohol.

Thiotepa may also be known as: NSC-6396, TESPA, thiophosphamide, triethylenethiophosphoramide, TSPA, WR-45312, *Ledertepa*®, *Onco Tiotepa*®, *Tespamin*®, or *Thioplex*®.

Storage/Stability

Store both the powder and the reconstituted solution refrigerated (2–8°C) and protected from light. Do not use solution that is grossly opaque (slightly opaque is OK) or if a precipitate is present. If refrigerated, reconstituted solutions are stable for up to 5 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Thiotepa Lyophilized Powder for Injection: 15 mg & 30 mg in vials; *Thioplex*® (Amgen); generic, (Sicor); (Rx)

THYROTROPIN THYROTROPIN ALFA (rhTSH)

(thye-roe-troe-pin) Thyroid Stimulating Hormone, TSH
HORMONE

Prescriber Highlights

- Hormone used for thyroid stimulating hormone (TSH) test for thyroid function
- **Contraindications:** Adrenocortical insufficiency, hyperthyroidism, coronary thrombosis, hypersensitivity to bovine thyrotropin
- **Adverse Effects:** Hypersensitivity (especially with repeated injections)
- **Availability** (of bovine source TSH) and expense (human product) may be issues

Uses/Indications

The labeled indications for the formerly available veterinary product *Dermathycin*® (Mallinckrodt) was for “the treatment of acanthosis nigricans and for temporary supportive therapy in hypothyroidism in dogs.” In actuality however, TSH is used in veterinary medicine principally as a diagnostic agent in the TSH stimulation test to diagnose primary hypothyroidism.

Pharmacology/Actions

Thyrotropin increases iodine uptake by the thyroid gland and increases the production and secretion of thyroid hormones. With prolonged use, hyperplasia of thyroid cells may occur.

Pharmacokinetics

No specific information was located; exogenously administered TSH apparently exerts maximal increases in circulating T₄ approximately 4–8 hours after IM or IV administration.

Contraindications/Precautions/Warnings

A previous veterinary manufacturer (Coopers), listed adrenocortical insufficiency and hyperthyroidism as contraindications to TSH use for treatment purposes in dogs. In humans, TSH is contraindicated in patients with coronary thrombosis, untreated Addison’s disease, or hypersensitive to bovine thyrotropin.

Adverse Effects

Because the product is derived from bovine sources, anaphylaxis may occur in patients sensitive to bovine proteins, particularly with repeated use.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether the drug is excreted in human milk, but is unlikely to be clinically significant when used for diagnostic purposes.

Overdosage/Acute Toxicity

Chronic administration at high dosages can produce clinical signs of hyperthyroidism. Massive overdoses can cause clinical signs resembling thyroid storm. Refer to the levothyroxine monograph for more information on treatment.

Drug Interactions; Laboratory Considerations

Refer to the information listed in the Levothyroxine monograph for more information.

Doses**■ DOGS:**

For TSH stimulation test:

- Draw pre-dose baseline sample. Administer 0.1 IU/kg IV (maximum of 5 IU). Collect sample for T₄ 6 hours after dose. (Peterson and Ferguson 1989)
- 5 IU IV or 0.1 IU/kg IV. Measure serum T₄ at 0 hours (pre-sample) and 4 or 6 hours after dose (Morgan 1988)
- Using the bovine product: Measure pre-dose (basal) T₄; then 0.1 Units/kg (maximum of 5 Units) IV. Measure post-dose T₄ at 6 hours.

Using the human recombinant product: 50–100 mcg (0.05–0.1 mg) IV; Measure serum T₄ at 0 hours (pre-sample) and 4 hours post. Product may be frozen for at least 8 weeks with no loss of potency. (Scott-Moncrieff 2006b)

■ CATS:

For TSH stimulation test:

- Draw pre-dose baseline sample. Administer 1 IU/kg IV or 2.5 IU IM. Collect sample for T₄ 6 hours after dose. (Peterson and Ferguson 1989)
- 2.5 IU IV. Measure serum T₄ at 0 hours (pre-sample) and 4 or 6 hours after dose. (Morgan 1988)

■ HORSES:

For TSH stimulation test:

- Draw pre-dose sample, then 5–10 IU of bovine TSH IV. Draw follow-up samples 4–8 hours after dosing. Normal thyroid gland should produce a 2–4 times increase in serum T₃ and T₄ levels. (Chen and Li 1987)

Client Information

- Usually, TSH will be administered by professional staff

Chemistry/Synonyms

Commercially available thyrotropin (human; rhTSH) is now available only as a lyophilized powder for reconstitution obtained via DNA recombinant technology. Originally obtained from bovine anterior pituitary glands, thyrotropin is a highly purified preparation of thyroid-stimulating hormone (TSH). Thyrotropin is a glycoprotein and has a molecular weight of approximately 28,000–30,000. Thyrotropin is measured in International Units (IU), with 7.5 micrograms of thyrotropin approximately equivalent to 0.037 units.

Thyrotropin may also be known as: thyroid-stimulating hormone, thyrotrophic hormone, thyrotropin, TSH, *Ambinon*®, *Thyreostimulin*®, *Thyrogen*®, or *Thytropar*®.

Storage/Stability

Thyrotropin alfa (unreconstituted) should be stored between 2–8°C (36–46°F). If necessary, the reconstituted solution can be stored up to 24 hours between 2–8°C (36–46°F), while avoiding microbial contamination. However, it is reportedly stable if kept refrigerated (2–8°C) up to 4 weeks and up to 8 weeks if frozen (-20°C).

After reconstitution visually inspect each vial for particulate matter or discoloration before use. Do not use any vial exhibiting particulate matter or discoloration. Do not use after the expiration date on the vial. Protect from light.

Thyrotropin lyophilized powder for injection (Bovine) is reportedly stable in the dry state. However, the veterinary manufacturer recommended storing the powder below 59°F, and after reconstituting, storing in the refrigerator and discarding any unused drug after 48 hours. It has been suggested however, that reconstituted TSH (bovine) is stable for at least 3 weeks when refrigerated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Thyrotropin (Thyroid Stimulating Hormone) Powder for Injection, Lyophilized: 1.1 mg thyrotropin alfa (less than or equal to 4 IU)/vial in kits of two 1.1 mg single-use vials of thyrotropin alfa and two 10 mL vials of diluent; *Thyrogen*® (Genzyme); (Rx)

Thyroxine Sodium—See Levothyroxine Sodium

TIAMULIN

(tye-am-myoo-lin) Denagard®

DITERPINE ANTIBIOTIC**Prescriber Highlights**

- Antibiotic used primarily in swine
- Contraindications: Access to feeds containing polyether ionophores (e.g., monensin, lasalocid, narasin, or salinomycin); swine over 250 pounds
- Adverse Effects are unlikely
- Variable withdrawal times depending on dosage

Uses/Indications

Tiamulin is approved for use in swine to treat pneumonia caused by susceptible strains of *Haemophilus pleuropneumoniae* and swine dysentery caused by *Treponema hyodysenteriae*. As a feed additive, it is used to cause increased weight gain in swine.

Pharmacology/Actions

Tiamulin is usually a bacteriostatic antibiotic, but can be bactericidal in very high concentrations against susceptible organisms. The drug acts by binding to the 50S ribosomal subunit, thereby inhibiting bacterial protein synthesis.

Tiamulin has good activity against many gram-positive cocci, including most Staphylococci and Streptococci (not group D streps). It also has good activity against Mycoplasma and spirochetes. With the exception of *Haemophilus* spp. and some *E. coli* and Klebsiella strains, the drug's activity is quite poor against gram-negative organisms.

Pharmacokinetics

Tiamulin is well absorbed orally by swine. Approximately 85% of a dose is absorbed and peak levels occur between 2–4 hours after a single oral dose. Tiamulin is apparently well distributed, with highest levels found in the lungs.

Tiamulin is extensively metabolized to over 20 metabolites, some having antibacterial activity. Approximately 30% of these metabolites are excreted in the urine with the remainder excreted in the feces.

Contraindications/Precautions/Warnings

Tiamulin should not be administered to animals having access to feeds containing polyether ionophores (e.g., monensin, lasalocid, narasin, or salinomycin) as adverse reactions may occur. Not for use in swine over 250 pounds.

Reproductive/Nursing Safety

Teratogenicity studies done in rodents demonstrated no teratogenic effects at doses up to 300 mg/kg. The manufacturer has concluded that the drug is not tumorigenic, carcinogenic, teratogenic, or mutagenic.

Adverse Effects

Adverse effects occurring with this drug at usual doses are considered unlikely. Rarely, redness of the skin, primarily over the ham and underline, has been observed. It is recommended to discontinue the medication, provide clean drinking water, and hose down the area or move affected animals to clean pens.

Overdosage/Acute Toxicity

Oral overdoses in pigs may cause transient salivation, vomiting, and CNS depression (calming effect). Discontinue drug and treat symptomatically and supportively if necessary.

Drug Interactions

- **POLYETHER IONOPHORES** (e.g., monensin, lasalocid, narasin, or salinomycin): Tiamulin should not be administered to animals having access to feeds containing polyether ionophores as adverse reactions may occur
- **LINCOSAMIDES, MACROLIDES** (e.g., clindamycin, lincomycin, erythromycin, tylosin): Although not confirmed with this drug, concomitant use with other antibiotics that bind to the 50S ribosome could lead to decreased efficacy secondary to competition at the site of action

Doses

- **SWINE:**
 - a) For swine dysentery: 7.7 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; *Denagard® Liquid Concentrate*)
 - b) For swine pneumonia: 23.1 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; *Denagard® Liquid Concentrate*)
 - c) For use as a medicated premix: See the label for the product.

Monitoring

- Clinical efficacy

Client Information

- Prepare fresh medicated water daily
- Avoid contact with skin or mucous membranes as irritation may occur

Chemistry/Synonyms

A semisynthetic diterpene-class antibiotic derived from pleuromulin, tiamulin is available commercially for oral use as the hydrogen fumarate salt. It occurs as white to yellow, crystalline powder with a faint but characteristic odor. Approximately 60 mg of the drug are soluble in 1 mL of water.

Tiamulin may also be known as: 81723-hfu, SQ-14055, SQ-22947 (tiamulin fumarate), and *Denagard®*.

Storage/Stability

Protect from moisture; store in a dry place. In unopened packets, the powder is stable up to 5 years. Fresh solutions should be prepared daily when using clinically.

Dosage Forms/Regulatory Status

VETERINARY APPROVED PRODUCTS:

Tiamulin Medicated Premix: 10 g/1 lb in 35 lb bags. Approved for use in swine not weighing over 250 lbs. Slaughter withdrawal period at the 35 g/ton use is 2 days and at the 200 g/ton dose is 7 days. *Denagard® 10* (Novartis); (OTC)

Tiamulin Solution: 12.3% tiamulin hydrogen fumarate in an aqueous base in 32 oz bottles. Approved for use in swine. Slaughter withdrawal: treatment at 3.5 mg/lb = 3 days, at 10.5 mg/lb = 7 days. *Denagard® Liquid Concentrate* (Boehringer Ingelheim); *Amtech® Tiamulin Liquid Concentrate* (IVX); (OTC)

Tiamulin Soluble Powder: 45% in 2.28 oz packets (29.1 g tiamulin per packet). Approved for use in swine. Slaughter withdrawal: treatment at 3.5 mg/lb = 3 days, at 10.5 mg/lb = 7 days. *Denagard® Liquid Concentrate* (Boehringer Ingelheim); *Amtech® Tiamulin Soluble Antibiotic* (IVX); (OTC)

HUMAN APPROVED PRODUCTS: None

TICARCILLIN DISODIUM

(tye-kar-sill-in) Ticar®

PARENTERAL EXTENDED SPECTRUM PENICILLIN

Prescriber Highlights

- Parenteral, anti-pseudomonal penicillin
- Contraindications: Known hypersensitivity (unless no other options)
- Adverse Effects: Hypersensitivity possible; very high doses may cause CNS effects. Potentially could cause bleeding
- Treatment is relatively expensive

Uses/Indications

A ticarcillin disodium product was approved for intrauterine use in horses in the treatment of endometritis in horses caused by beta hemolytic streptococci, but is apparently no longer marketed.

Ticarcillin disodium injection is used in veterinary species in the treatment of systemic *Pseudomonas aeruginosa* infections, often in combination with an appropriate aminoglycoside agent. When compared with carbenicillin, ticarcillin is about twice as potent (on a per weight basis) in the treatment against susceptible *Pseudomonas*. Synergy may occur against some *Pseudomonas* strains when used in combination with aminoglycosides, but *in vitro* inactivation of the aminoglycoside may also occur (see Drug Interactions) if the

drugs are physically mixed together or in patients with severe renal failure.

Ticarcillin (alone and with clavulanate) has been used in a variety of compounded preparations for otic use.

Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The extended-spectrum penicillins, sometimes called antipseudomonal penicillins, include both alpha-carboxypenicillins (carbenicillin and ticarcillin) and acylaminopenicillins (piperacillin, azlocillin, and mezlocillin). These agents have similar spectrums of activity as the aminopenicillins but with additional activity against several gram-negative organisms of the family Enterobacteriaceae, including many strains of *Pseudomonas aeruginosa*. Like the aminopenicillins, these agents are susceptible to inactivation by beta-lactamases.

Pharmacokinetics

Ticarcillin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum levels. When given IM to humans, the drug is readily absorbed with peak levels occurring about 30–60 minutes after dosing. The reported bioavailability in the horse after IM administration is about 65%.

After parenteral injection, ticarcillin is distributed into pleural fluid, interstitial fluid, bile, sputum, and bone. Like other penicillins, CSF levels are low in patients with normal meninges (about 6% of serum levels), but increased (39% of serum levels) if meninges are inflamed. The volume of distribution is reportedly 0.34 L/kg in dogs and 0.22–0.25 L/kg in the horse. The drug is 45–65% bound to serum proteins (human). Ticarcillin is thought to cross the placenta and found in small quantities in milk. In cattle, mastitic milk levels of ticarcillin are approximately twice those found in normal milk, but are too low to treat most causal organisms.

Ticarcillin is eliminated primarily by the kidneys, via both tubular secretion and glomerular filtration. Concurrent probenecid administration can slow elimination and increase blood levels. In humans, about 10–15% of the drug is metabolized by hydrolysis to inactive compounds. The half-life in dogs and cats is reportedly 45–80 minutes; about 54 minutes in the horse. Clearance is 4.3 mL/kg/min in the dog and 2.8–3.2 mL/kg/min in the horse.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Ticarcillin has significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Ticarcillin has been implicated in causing bleeding problems in humans; veterinary ramifications of this potential effect are unclear.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Although penicillins can be distributed into milk, it is unlikely that ticarcillin would be of clinical concern in nursing veterinary patients.

Overdosage/Acute Toxicity

In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ticarcillin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (e.g., amikacin, gentamicin, tobramycin): *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides; however, beta-lactam antibiotics can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **PROBENECID**: Can reduce the renal tubular secretion of ticarcillin, thereby maintaining higher systemic levels for a longer period of time
- **WARFARIN; HEPARIN**: As ticarcillin has been implicated in rarely causing bleeding, use with caution in patients receiving anticoagulant therapy

Laboratory Considerations

- **Aminoglycoside serum quantitative analysis:** As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- **Direct antiglobulin (Coombs') tests:** False-positive results may occur
- **Urine protein:** May produce false-positive protein results with the sulfosalicylic acid and boiling test, nitric acid test, and the acetic acid test. Strips using bromophenol blue reagent (e.g., *Multi-Stix*®) do not appear to be affected by high levels of penicillins in the urine

Doses

■ DOGS:

For susceptible infections:

- a) For susceptible (to ticarcillin) infections demonstrated to be resistant to other less expensive and more convenient antibiotics. Ticarcillin: 15–25 mg/kg as an IV infusion over 15 minutes, followed by a constant rate IV infusion at 7.5–15 mg/kg/hour (Trepanier 1999)
- b) For treatment of *Pseudomonas aeruginosa* infections in conjunction with an aminoglycoside: 50–75 mg/kg IV or IM q8h (Aucoin 2002b)
- c) For soft tissue, systemic infections: 15–25 mg/kg IV, IM, SC q6–8h as long as necessary;
For septicemia: 40–50 mg/kg IV, IM q4–6h as long as necessary;
For difficult, severe systemic infections: 100 mg/kg IV q6–8h as long as necessary. (Greene, Hartmann et al. 2006)
- d) As an otic solution for adjunctive treatment of *Pseudomonas* otitis using ticarcillin: Dilute according to manufacturer's directions to a concentration of 2 mg/mL and apply 5–10 drops per ear every 12 hours. (Kwochka 2003a)

■ CATS:

For susceptible infections:

- a) For susceptible (to ticarcillin) infections demonstrated to be resistant to other less expensive and more convenient antibiotics. Ticarcillin: 15–25 mg/kg as an IV infusion over 15 minutes, followed by a constant rate IV infusion at 7.5–15 mg/kg/hour (Trepanier 1999)
- b) For treatment of *Pseudomonas aeruginosa* infections in conjunction with an aminoglycoside: 50–75 mg/kg IV or IM q8h (Aucoin 2002b)
- c) For *Pseudomonas* soft tissue, systemic infections: 15–24 mg/kg IV, IM, SC q8h as long as necessary;
For *Pseudomonas* systemic, bacteremia: 40–50 mg/kg IV q6h as long as necessary. (Greene, Hartmann et al. 2006)

■ HORSES:

For susceptible systemic infections:

- a) 22–44 mg/kg IV q6h. (Bertone 2003a)
- b) Foals: 40–60 mg/kg IV, IM q6–8h (Brumbaugh 1999)
- c) Foals: 50 mg/kg q6h IV or IM (Furr 1999)

For treatment of endometritis secondary to susceptible bacteria:

- a) 6 grams intrauterine per day for 3 days during estrus. Reconstitute vial with 25 mL of Sterile Water for Injection, USP or Sodium Chloride Injection, USP. After dissolved, further dilute to a total volume of 100–500 mL with sterile water or sterile normal saline and aseptically instill into uterus. (Package insert; *Ticillin*®—Beecham)

■ BIRDS:

For susceptible infections:

- a) 200 mg/kg IV or IM twice daily, three times daily or four times daily (Clubb 1986)
- b) 200 mg/kg IM or IV q8h (Hoeffer 1995)

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Chemistry/Synonyms

An alpha-carboxypenicillin, ticarcillin disodium occurs as a white to pale yellow, hygroscopic powder or lyophilized cake with pK_as of 2.55 and 3.42. More than 600 mg is soluble in 1 mL of water. Potency of ticarcillin disodium is expressed in terms of ticarcillin and one gram of the disodium contains not less than 800 mg of ticarcillin anhydrous. One gram of the commercially available injection contains 5.2–6.5 mEq of sodium and after reconstituting the injection has a pH of 6–8.

Ticarcillin Disodium may also be known as: BRL-2288, ticarcillinum natricum, *Aerugipen*®, *Tarcil*®, *Ticar*®, *Ticarpen*®, *Ticillin*®, or *Triacilline*®.

Storage/Stability/Compatibility

Ticarcillin injectable powder for injection should be stored at temperatures of less than 30°C (room temperature or colder).

If stored at room temperature after reconstitution, polymer conjugates can form that may increase the likelihood of hypersensitivity reactions occurring, therefore, many clinicians recommend either refrigerating the solution or administering within 30 minutes of reconstitution. From a potency standpoint, the drug should be used generally within 24 hours if stored at room temperature and 72 hours if refrigerated, but the manufacturer has specific recommendations on stability depending on the concentration of the drug and the solution used; refer to the package insert. Frozen solutions are reportedly stable for at least 30 days when stored at -20°C.

Ticarcillin disodium solutions are reportedly physically **compatible** with the following solutions and drugs: D5W, Ringer's Injection, Lactated Ringer's Injection, sodium chloride 0.9%, Sterile water for injection, acyclovir sodium, hydromorphone HCl, meperidine HCl, methylprednisolone sodium succinate, morphine sulfate, ranitidine HCl, perphenazine, and verapamil HCl.

Ticarcillin disodium solutions are reportedly physically **incompatible** with the aminoglycoside antibiotics; refer to the drug interaction information in the Penicillins, General Information monograph for more information. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ticarcillin Disodium Powder for Injection: (contains 5.2 mEq sodium/g) 3 g in vials; *Ticar*® (GlaxoSmithKline); (Rx)

TICARCILLIN DISODIUM + CLAVULANATE POTASSIUM

(tye-kar-sill-in; klav-yoo-lan-ate) Timentin®

PARENTERAL EXTENDED SPECTRUM
PENICILLIN + BETA-LACTAMASE INHIBITOR

Prescriber Highlights

- ▶ Parenteral, extended action penicillin with a beta lactamase inhibitor; has increased spectrum of activity when compared with ticarcillin alone, but is more expensive
- ▶ Used for serious systemic infections & as a compounded otic prep for *Pseudomonas* otitis
- ▶ Limited experience or research in veterinary medicine, but appears quite safe
- ▶ Patients with significantly impaired renal function or those receiving very high dosages may be more prone to develop platelet function abnormalities (bleeding) or CNS effects

Uses/Indications

Ticarcillin/clavulanate is used systemically to treat serious infections such as sepsis or nosocomial pneumonias in dogs, cats and horses. By adding clavulanate, enhanced spectrum of activity against beta-lactamase producing bacteria can be obtained. This drug combination is sometimes used to treat *Pseudomonas* otitis in dogs.

Pharmacology/Actions

See the Ticarcillin monograph for information on ticarcillin. By adding clavulanate, ticarcillin's efficacy can be extended against beta-lactamase-producing strains of otherwise resistant *E. coli*, *Pasturella* spp., *Staphylococcus* spp., *Klebsiella*, and *Proteus*. Clavulanic acid acts by competitively and irreversibly binding to beta-lactamases, including types II, III, IV, and V, and penicillinases produced by *Staphylococcus*. Type I beta-lactamases that are often associated with *E. coli*, *Enterobacter*, and *Pseudomonas* are not generally inhibited by clavulanic acid.

Clavulanic acid has only weak antibacterial activity when used alone and at present is only available in fixed-dose combinations with either amoxicillin (oral) or ticarcillin (parenteral). Unlike sulbactam or tazobactam, clavulanic acid (clavulanate) can induce chromosomal beta-lactamases.

Synergy against *Pseudomonas aeruginosa* can occur when used with an aminoglycoside, but the drugs cannot be mixed together (see Drug Interactions).

Pharmacokinetics

Ticarcillin pharmacokinetics are presented in the monograph preceding this one. There is no evidence to suggest that the addition of clavulanic acid alters ticarcillin pharmacokinetics.

Clavulanic acid has an apparent volume of distribution of 0.32 L/kg in dogs and is distributed (with ticarcillin) into the lungs, pleural fluid and peritoneal fluid. Low concentrations of both drugs are found in the saliva, sputum and CSF (uninflamed meninges). Higher concentrations in the CSF are expected when meninges are inflamed, but it is questionable whether therapeutic levels are attainable. Clavulanic acid is 13% bound to proteins in dog serum. Clavulanic acid is extensively metabolized in the dog (and rat) primarily to 1-amino-4-hydroxybutan-2-one. It is not known if this compound possesses any beta-lactamase inhibiting activity.

Clavulanic acid is also excreted unchanged in the urine via glomerular filtration. In dogs, 34–52% of a dose is excreted in the urine as unchanged drug and metabolites, 25–27% in the feces, and 16–33% into respired air. The elimination half-life for clavulanic acid in dogs is faster than is ticarcillin.

Contraindications/Precautions/Warnings

Do not use this medication in patients with documented hypersensitivity reactions to penicillins or other beta-lactams.

Dosage adjustments should be made in patients with significantly impaired renal function.

Adverse Effects

Although clinical experience with this medication in veterinary patients is limited, it appears to be well tolerated; potentially, hypersensitivity reactions can occur. In humans, high dosages (particularly in patients with renal insufficiency) have caused platelet dysfunction and bleeding, and CNS effects (headache, giddiness, hallucinations, seizures). Intramuscular administration can cause pain, but reconstituting with 1% lidocaine (see Storage/Stability/Compatibility) can alleviate this effect. Local irritation to veins after IV administration is possible and best avoided by using dilute concentrations administered over not less than 30 minutes.

Antibiotic-associated diarrhea or colitis may occur.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes ticarcillin/clavulanate as category B for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Although penicillins can be distributed into milk, it is unlikely that ticarcillin/clavulanate would be of significant clinical concern for nursing veterinary patients.

Overdosage/Acute Toxicity

A single inadvertent overdose is unlikely to cause significant morbidity. In humans, very high dosages of parenteral penicillins such as ticarcillin, especially in patients with renal disease, have induced CNS effects (hallucinations, headaches, seizures) and alterations in platelet function (bleeding).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ticarcillin/clavulanate and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (e.g., amikacin, gentamicin, tobramycin): *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. However, beta-lactam antibiotics can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **PROBENECID**: Can reduce the renal tubular secretion of ticarcillin, thereby maintaining higher systemic levels for a longer period of time; it does not affect the elimination of clavulanate

- **WARFARIN; HEPARIN:** As ticarcillin has been implicated in rarely causing bleeding, use with caution in patients receiving anticoagulant therapy

Laboratory Considerations

- **Aminoglycoside serum quantitative analysis:** As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.
- **Direct antiglobulin (Coombs') tests:** False-positive results may occur
- **Urine protein:** May produce false-positive protein results with the sulfosalicylic acid and boiling test, nitric acid test, and the acetic acid test. Strips using bromophenol blue reagent (e.g., *Multi-Stix*®) do not appear to be affected by high levels of penicillins in the urine

Doses

Note: Unless otherwise indicated, this drug combination is dosed on the basis of ticarcillin content.

■ DOGS:

- For sepsis: 40–50 mg/kg q6–8h IV (Hardie 2000)
- 15–50 mg/kg q6–8h IV, IM or SC (Lappin 2003c)
For *Pseudomonas* sepsis/bacteremia: 20–50 mg/kg IV q6–8h (Greene, Hartmann et al. 2006)
- As an otic solution for adjunctive treatment of *Pseudomonas* otitis using the ticarcillin/clavulanic acid product—*Timentin*®: Dilute according to manufacturer's directions, then draw into 2 mL aliquots and freeze. Thaw and use each aliquot as 0.5 mL in each ear, twice daily. (White 2003c)

■ CATS:

- For sepsis: 40–50 mg/kg q6–8h IV (Hardie 2000)
- For *Pseudomonas* sepsis/bacteremia: 40 mg/kg IV q6h (Greene, Hartmann et al. 2006)
- 50 mg/kg IV or IM 4 times daily; may need more frequent dosing or constant rate infusion for resistant *Pseudomonas* infections (Trepanier 1999)
- 15–50 mg/kg q6–8h IV, IM or SC (Lappin 2003c)

■ HORSES:

For susceptible infections:

- 50 mg/kg IV q6h (Bertone 2003a)
- Foals (neonatal septicemia): 40–60 mg/kg IV or IM q8h (Paradis 2003)
- Foals: 50 mg/kg IV or IM q6–8h (Brumbaugh 1999)

Monitoring

- Efficacy for the infection treated (WBC, clinical signs, etc.)
- Serum levels and therapeutic drug monitoring are not routinely performed with this drug

Client Information

- Limited experience in veterinary medicine when used systemically
- Best suited for inpatient use

Chemistry/Synonyms

An alpha-carboxypenicillin, ticarcillin disodium occurs as a white to pale yellow, hygroscopic powder or lyophilized cake with pK_as of 2.55 and 3.42. More than 600 mg is soluble in 1 mL of water. Potency of ticarcillin disodium is expressed in terms of ticarcillin and one gram of the disodium contains not less than 800 mg of ticarcillin anhydrous. One gram of the commercially available injection contains 5.2–6.5 mEq of sodium.

A beta-lactamase inhibitor, clavulanate potassium occurs as an off-white, crystalline powder that has a pK_a of 2.7 (as the acid) and is very soluble in water and slightly soluble in alcohol at room temperatures. Although available commercially as the potassium salt, potency is expressed in terms of clavulanic acid.

Ticarcillin Disodium may also be known as: BRL-2288, or ticarcillinum natricum. Clavulanate potassium may also be known by the following synonyms: clavulanic acid, BRL-14151K, or kalii clavulanate. International trade names for ticarcillin/clavulanate include *Timentin*® and *Claventin*®.

Storage/Stability/Compatibility

Unused vials should be stored at room temperature (below 24°C, 75°F).

A darkening of the sterile powder or solution indicates degradation and loss of potency of clavulanate.

For IM use, reconstitute vial with 2 mL of sterile water for injection, sodium chloride for injection, or 1% lidocaine (without epinephrine) per gram of ticarcillin. Each mL of the resulting solution will contain approximately 385 mg/mL (1 gram per 2.6 mL) ticarcillin. For humans, IM injections are recommended to be made into a relatively large muscle and not to administer more than one gram (2.6 mL) IM per injection site.

For IV use, initially reconstitute 3.1 gram vials with 13 mL of sodium chloride injection, dextrose 5% or LRS. Resulting solution will contain approximately 200 mg of ticarcillin per mL. If administered IV at this concentration, give as slowly as possible. Ideally, dilute further to a concentration of 10–100 mg (ticarcillin)/mL with a suitable diluent (e.g., NS, LRS, D5W). Concentrations of 50 mg/mL or less will cause less vein irritation; the solution should be administered as slowly as possible (over at least 30 minutes).

When vials are reconstituted (as above) to 200 mg/mL, the resulting solution is stable for 6 hours at room temperature and 72 hours when refrigerated. Stability for solutions diluted for IV infusion (10–100 mg/mL):

DILUENT	ROOM TEMP	REFRIGERATED	FROZEN
NS	24 hrs	7 days	30 days
D5W	24 hrs	3 days	7 days
LRS	24 hrs	7 days	30 days

All thawed solutions should be used within 8 hours and not refrozen.

Ticarcillin/clavulanate should not be mixed with aminoglycosides (e.g., gentamicin, amikacin) and may not be **compatible** when infused at a Y-site with solutions containing amphotericin B cholesterol sulfate complex, azithromycin, or vancomycin. Y-site **compatible** drugs include (partial listing): propofol, dexmetomidine, cefepime, diltiazem, doxorubicin HCl liposomes, etoposide, famotidine, fluconazole, heparin sodium, hetastarch, regular insulin, meperidine, morphine sulfate, and ondansetron.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Ticarcillin Disodium Powder for Injection (contains 4.75 mEq sodium/g) and Clavulanate Potassium (contains 0.15 mEq potassium/g): 3 g ticarcillin and 0.1g clavulanic acid in 3.1 g vials, piggyback bottles, ADD-Vantage vials and 31 g pharmacy bulk packages; *Timentin*® (GlaxoSmithKline); (Rx)

Ticarcillin Powder for Injection (contains 18.7 mEq sodium/100 mL) and Clavulanate Potassium (contains 0.5 mEq potassium/100 mL): 3 g ticarcillin and 0.1 g clavulanic acid/100 mL in 100 mL premixed, frozen Galaxy plastic containers; *Timentin*® (GlaxoSmithKline); (Rx)

TILETAMINE HCL/ZOLAZEPAM HCL

(tye-let-a-meen and zoe-laze-a-pam) Telazol®

INJECTABLE ANESTHETIC/TRANQUILIZER**Prescriber Highlights**

- ▶ **Injectable anesthetic/tranquilizer combination similar to ketamine/diazepam**
- ▶ **Contraindications:** Pancreatic disease, rabbits, severe cardiac disease, use in cesarean section, or pulmonary disease
- ▶ **Caution:** Renal disease, large exotic cats (use avoided)
- ▶ **Protect patient's eyes after using**
- ▶ **Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.**
- ▶ **Adverse Effects:** Respiratory depression, pain after IM injection, athetoid movements, tachycardia (esp. dogs), emesis during emergence, excessive salivation & bronchial/tracheal secretions, transient apnea, vocalization, erratic &/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, & either hypertension or hypotension
- ▶ **Monitor body temperature (may cause hypothermia)**
- ▶ **Class-III controlled substance**

Uses/Indications

Telazol® is indicated for restraint or anesthesia combined with muscle relaxation in cats, and for restraint and minor procedures of short duration (≈30 minutes) which require mild to moderate analgesia in dogs. Although not officially approved, it has been used also in horses and many exotic and wild species.

Pharmacology/Actions

In cats, tiletamine decreases cardiac rate and blood pressure after IM injections. Its effect on respiratory activity is controversial, and until these effects have been clarified, respiratory function should be closely monitored. The pharmacology of this drug combination is similar to that of ketamine and diazepam; for more information, refer to their monographs.

Pharmacokinetics

Little pharmacokinetic information is available for these agents. The onset of action may be variable and be very rapid; animals should be observed carefully after injection.

In cats, the onset of action is reported to be within 1–7 minutes after IM injection. Duration of anesthesia is dependent on dosage, but is usually about 0.33–1 hour at peak effect. This is reported to be approximately 3 times the duration of ketamine anesthesia. The duration of effect of the zolazepam component is longer than that of the tiletamine, so there is a greater degree of tranquilization than anesthesia during the recovery period. The recovery times vary in length from approximately 1–5.5 hours.

In dogs, the onset of action following IM injection averages 7.5 minutes. The mean duration of surgical anesthesia is about 27 minutes, with recovery times averaging approximately 4 hours. The duration of the tiletamine effect is longer than that of zolazepam, so there is a shorter duration of tranquilization than there is anesthesia. Less than 4% of the drugs are reported excreted unchanged in the urine in the dog.

Contraindications/Precautions/Warnings

Telazol® is contraindicated in animals with pancreatic disease, or severe cardiac or pulmonary disease. Animals with renal disease may have prolonged duration of anesthetic action or recovery times.

Because *Telazol*® may cause hypothermia, susceptible animals (small body surface area, low ambient temperatures) should be monitored carefully and supplemental heat applied if needed. Like ketamine, *Telazol*® does not abolish pinnal, palpebral, pedal, laryngeal, and pharyngeal reflexes and its use (alone) may not be adequate if surgery is to be performed on these areas.

It has been reported that this drug is contraindicated in rabbits due to renal toxicity.

Telazol® is generally avoided for use in large, exotic cats (contraindicated in tigers) as it may cause seizures, permanent neurologic abnormalities, or death.

Cats' eyes remain open after receiving *Telazol*®, and they should be protected from injury and an ophthalmic lubricant (e.g., *Lacrilube*®) should be applied to prevent excessive drying of the cornea. Cats reportedly do not tolerate endotracheal tubes well with this agent.

Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.

Adverse Effects

Respiratory depression is a definite possibility, especially with higher dosages of this product. Apnea may occur; observe animal carefully. Pain after IM injection (especially in cats) has been noted which may be a result of the low pH of the solution. Athetoid movements (constant succession of slow, writhing, involuntary movements of flexion, extension, pronation, etc.) may occur; do not give additional *Telazol*® in the attempt to diminish these actions. Large doses given SC or IM, versus small doses given IV, may result in longer, rougher recoveries.

In dogs, tachycardia may be a common effect and last for 30 minutes. Insufficient anesthesia after recommended doses has been reported in dogs.

Telazol® has been implicated in causing nephrosis in lagomorphs (rabbits/hares) and is usually not recommended for use in these species.

Other adverse effects listed by the manufacturer include: emesis during emergence, excessive salivation and bronchial/tracheal secretions (if atropine not administered beforehand), transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, and either hypertension or hypotension.

Reproductive/Nursing Safety

Telazol® crosses the placenta and may cause respiratory depression in newborns; the manufacturer lists its use in cesarean section as being contraindicated. The teratogenic potential of the drug is unknown, and it is not recommended for use during any stage of pregnancy.

Overdosage/Acute Toxicity

The manufacturer claims a 2X margin of safety in dogs, and a 4.5 times margin of safety in cats. A preliminary study in dogs (Hatch et al. 1988) suggests that doxapram at 5.5 mg/kg will enhance respirations and arousal after *Telazol*®. In massive overdoses, it is suggested that mechanically assisted ventilation be performed if necessary and other clinical signs treated symptomatically and supportively.

Drug Interactions

Little specific information is available presently on drug interactions with this product.

- **ANESTHETICS, INHALATIONAL:** Dosage may need to be reduced when used concomitantly with *Telazol*®
- **BARBITURATES:** Dosage may need to be reduced when used concomitantly with *Telazol*®
- **CHLORAMPHENICOL:** In dogs, chloramphenicol apparently has no effect on recovery times with *Telazol*®, but in cats, anesthesia is prolonged on average of 30 minutes by chloramphenicol.
- **PHENOTHIAZINES:** Can cause increased respiratory and cardiac depression

For potential additional interactions from the related compounds, ketamine and midazolam:

Ketamine:

- **NEUROMUSCULAR BLOCKERS** (e.g., **succinylcholine** and **tubocurarine**): May cause enhanced or prolonged respiratory depression
- **THYROID HORMONES:** When given concomitantly with ketamine, thyroid hormones have induced hypertension and tachycardia in humans; beta-blockers (e.g., **propranolol**) may be of benefit in treating these effects

Midazolam:

- **ANESTHETICS, INHALATIONAL:** Midazolam may decrease the dosages required
- **AZOLE ANTIFUNGALS** (**ketoconazole**, **itraconazole**), **fluconazole**): May increase midazolam levels
- **CALCIUM CHANNEL BLOCKERS** (**diltiazem**, **verapamil**): May increase midazolam levels
- **CIMETIDINE:** May increase midazolam levels
- **CNS DEPRESSANTS, OTHER:** May increase the risk of respiratory depression
- **MACROLIDES** (**erythromycin**, **clarithromycin**): May increase midazolam levels
- **OPIATES:** May increase the hypnotic effects of midazolam and hypotension has been reported when used with meperidine.
- **PHENOBARBITAL:** May decrease peak levels and AUC of midazolam
- **RIFAMPIN:** May decrease peak levels and AUC of midazolam
- **THIOPENTAL:** Midazolam may decrease the dosages required

Doses

■ DOGS:

- a) For diagnostic purposes: 6.6–9.9 mg/kg IM
For minor procedures of short duration: 9.9–13.2 mg/kg IM;
If supplemental doses are necessary, give doses less than the initial dose and total dosage should not exceed 26.4 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert; *Telazol*®—Robins)
- b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002a)

■ CATS:

- a) 9.7–11.9 mg/kg IM for procedures such as dentistry, abscess treatment, foreign body removal, etc. For procedures that require mild to moderate levels of analgesia (lacerations, castration, etc.) use 10.6–12.5 mg/kg IM.
For ovariectomy and onychectomy use 14.3–15.8 mg/kg IM.
If supplemental doses are necessary, give doses less than the initial dose and the total dosage should not exceed 72 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert; *Telazol*®—Robins)
- b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002a)

■ RUMINANTS:

- As an induction agent for cattle, llamas/alpacas, goats, sheep:
- a) Xylazine at 0.05–0.1 mg/kg IV, IM, then *Telazol*® at 2–4 mg/kg IV (IM). Caution: xylazine can cause severe hypoxemia and pulmonary edema in sheep. (Haskell 2005a)

■ RABBITS, RODENTS, SMALL MAMMALS:

For chemical restraint:

- a) Gerbils: 20 mg/kg IP (in combination with xylazine 10 mg/kg) (Huerkamp 1995)
- b) Mice: 80–100 mg/kg IM.
Rats: 20–60 mg/kg IM.
Hamsters/Gerbils: 20–80 mg/kg IM.
Guinea pig: 10–80 mg/kg IM.
Rabbits: Not recommended (Burke 1999)
- c) Chinchillas: 20–40 mg/kg IM.
Hamsters: 50–80 mg/kg IP for immobilization/anesthesia.
Gerbils: 10–30 mg/kg IP.
Mice: 80 mg/kg IP for immobilization
Rats: 40 mg/kg IP for light anesthesia.
Guinea pigs: 40–60 mg/kg IM for immobilization (Adamcak and Otten 2000)

■ FERRETS:

As a sedative/analgesic:

- a) 22 mg/kg IM combined with glycopyrrolate (0.01 mg/kg IM). Rapid onset, but slow and rough recovery (3–4 hours) (Finkler 1999)
- b) *Telazol*® alone: 22 mg/kg IM;
Telazol® (1.5 mg/kg) plus xylazine (1.5 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM)
Telazol® (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

- a) Xylazine 1.1 mg/kg IV, 5 minutes prior to *Telazol*® at 1.65–2.2 mg/kg IV (Hubbell, Bednarski, and Muir 1989)

■ EXOTIC SPECIES:

- a) An extensive list of suggested *Telazol*® dosages may be found in the article by E. Schobert entitled, “*Telazol*® Use in Wild and Exotic Animals” in the October 1987 issue of Veterinary Medicine.
- b) For carnivorous mammals (not tigers): 2–4 mg/mL usually provides adequate restraint. (Suedmeyer 2003)

■ REPTILES:

- a) Large Snakes: 3 mg/kg IM to facilitate handling and anesthesia. Administer 30–45 minutes prior to handling. Sedation may persist for up to 48 hours. May also be used in Crocodilians at 4–8 mg/kg. (Heard 1999)
- b) 3–10 mg/kg IM. Lizards and snakes can generally be treated with lower end of dosage range and chelonians may require high end. If sedation is inadequate, may give incrementally up to the maximum dose. Monitor closely for apnea and ventilate if required. (Innis 2003)
- c) Significant interspecies and interpatient differences in effectiveness. At lower doses of 4–10 mg/kg sedation may be sufficient for some procedures (venipuncture, gastric lavage, intubation for inhalation anesthesia). At higher doses (15–40 mg/kg), recovery may be greatly prolonged. Suggest starting out at 7–15 mg/kg the first few times this is used on reptiles in your practice (and to use on your own “in house” pets first!), and then use increasing dosages as needed. (Funk 2002)

■ BIRDS:

- a) Ratites: 5 mg/kg IM or IV (Jenson 1998)

Monitoring

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Monitor eyes to prevent drying or injury
- Body temperature

Client Information

Should only be administered by individuals familiar with its use.

Chemistry/Synonyms

Tiletamine is an injectable anesthetic agent chemically related to ketamine. Zolazepam is a diazepamone minor tranquilizer. The pH of the injectable product, after reconstitution, is 2.2–2.8.

Tiletamine HCl may also be known as: CI-634, CL-399, CN-54521-2, or *Telazol*®.

Zolazepam HCl may also be known as: CI-716.

Storage/Stability

After reconstitution, solutions may be stored for 4 days at room temperature and 14 days if refrigerated. Do not use solutions that contain a precipitate or are discolored.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Tiletamine HCl (equivalent to 250 mg free base) and Zolazepam HCl (equivalent to 250 mg free base) as lyophilized powder/vial in 5 mL vials. When 5 mL of sterile diluent (sterile water) is added a concentration of 50 mg/mL of each drug (100 mg/mL combined) is produced; *Telazol*® (Fort Dodge); (Rx, C-III). Approved for use in cats and dogs. *Telazol*® is a Class-III controlled substance.

HUMAN-LABELED PRODUCTS: None

TILMICOSIN

(til-mi-coe-sin) Micotil®, Pulmotil®

MACROLIDE ANTIBIOTIC**Prescriber Highlights**

- Macrolide antibiotic used in cattle, sheep, & sometimes rabbits; used in swine as a medicated feed article
- Contraindications: Not to be used in automatically powered syringes or to be given IV
- May be fatal in swine (when injected) & non-human primates; potentially in horses
- Adverse Effects: IM injections may cause a local tissue reaction resulting in trim loss; edema is possible at SC injection site
- Avoid contact with eyes
- In case of human injection, contact physician immediately

Uses/Indications

Tilmicosin is indicated for the treatment of bovine or ovine respiratory diseases (BRD) caused by *Mannheimia* (*Pasturella*) *haemolytica*.

Pharmacology/Actions

Like other macrolides, tilmicosin has activity primarily against gram-positive bacteria, although some gram-negative bacteria are affected and the drug reportedly has some activity against mycoplasma. Preliminary studies have shown that 95% of studied isolates of *Pasturella haemolytica* are sensitive.

Pharmacokinetics

Tilmicosin apparently concentrates in lung tissue. At 3 days post injection, the lung:serum ratio is about 60:1. MIC₉₅ concentrations (3.12 micrograms/mL) for *P. Haemolytica* persist for a minimum of 3 days after a single injection.

Contraindications/Precautions/Warnings

Not to be used in automatically powered syringes or to be given intravenously as fatalities may result. Tilmicosin has been shown to be fatal in swine (when injected), non-human primates and potentially, in horses.

Avoid contact with eyes. Accidental self-injection can be fatal in humans. Do not use in automatically powered syringes. Emergency treatment includes applying ice to injection site and contacting a physician immediately. Emergency medical telephone numbers are 1-800-722-0987 or 1-317-276-2000.

Adverse Effects

If administered IM, a local tissue reaction may occur resulting in trim loss. Edema may be noted at the site of subcutaneous injection.

Reproductive/Nursing Safety

Safe use in pregnant animals or animals to be used for breeding purposes has not been demonstrated.

Overdosage/Acute Toxicity

The cardiovascular system is apparently the target of toxicity in animals. In cattle, doses up to 50 mg/kg IM did not cause death, but SC doses of 150 mg/kg did cause fatalities, as well as IV doses of 5 mg/kg. Doses as low as 10 mg/kg in swine caused increased respiration, emesis and seizures; 20 mg/kg IM caused deaths in most animals tested. In monkeys, 10 mg/kg administered once caused no signs of toxicity, but 20 mg/kg caused vomiting; 30 mg/kg caused death.

In cases of human injection, contact physician immediately. The manufacturer has emergency telephone numbers to assist in dealing with exposure: 1-800-722-0987 or 1-317-276-2000.

Drug Interactions

In swine, **epinephrine** increased the mortality associated with tiludronate. No other specific information was noted; refer to the erythromycin monograph for potential interactions.

Doses

■ CATTLE:

For susceptible infections (subcutaneous injection under the skin in the neck, or if not accessible, behind the shoulders and over the ribs is suggested).

- For treatment of pneumonic pasteurellosis: 10 mg/kg SC every 72 hours (Shewen and Bateman 1993)
- Package insert (*Micotil*® 300—Elanco): 10 mg/kg SC (not more than 15 mL per injection site)

■ SHEEP:

For susceptible infections:

- 10 mg/kg SC (not more than 15 mL per injection site). Subcutaneous injection under the skin in the neck, or if not accessible, behind the shoulders and over the ribs is suggested. Do not use in lambs less than 15 kg of body weight. (Package insert; *Micotil*® 300—Elanco)

■ RABBITS, RODENTS, SMALL MAMMALS:

Rabbits: Two regimens:

- 25 mg/kg SC once; repeat in 3 days if necessary.
- 5 mg/kg SC on day 0, if no reaction, give 10 mg/kg SC on days 7 and 14. Can cause weakness, pallor, tachypnea and sudden death. May cause acute death if given IV. SC injections can cause local swelling and necrosis. (Ivey and Morrissey 2000)

Monitoring

- Efficacy
- Withdrawal times

Client Information

- If clients are administering the drug, they should be warned about the potential toxicity to humans, swine, and horses if accidentally injected
- Carefully instruct in proper injection techniques
- Avoid contact with eyes

Chemistry/Synonyms

A semi-synthetic macrolide antibiotic, tiludronate phosphate is commercially available in a 300 mg/mL (of tiludronate base) injection with 25% propylene glycol.

Tiludronate may also be known as EL-870, LY-177370, *Micotil*® or *Pulmotil*®.

Storage/Stability/Compatibility

Store the injection at or below room temperature. Avoid exposure to direct sunlight.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tiludronate for Subcutaneous Injection: 300 mg/mL in 50 mL, 100 mL and 250 mL multi-dose vials; *Micotil*® 300 Injection (Elanco); (Rx). Approved for use in cattle and sheep. Not approved for use in female dairy cattle 20 months or older. Do not use in lactating ewes if milk is to be used for human consumption. Do not use in veal calves. Slaughter withdrawal (at labeled doses) = 28 days.

Tiludronate Feed Medication: 90.7 g/lb. *Pulmotil*® 90 (Elanco); (OTC). Approved for veterinary use in swine only. Slaughter withdrawal (at labeled doses) = 7 days.

HUMAN-LABELED PRODUCTS: None

TILUDRONATE DISODIUM TILUDRONIC ACID

(til-yoo-droe-nate) Tildren®, Skelid®

BISPHOSPHONATE BONE RESORPTION INHIBITOR

Prescriber Highlights

- Bisphosphonate bone resorption inhibitor available in some countries for the intravenous treatment of navicular disease in horses
- Adverse effects: Signs of colic, muscle tremor (hypocalcemia), fatigue/lassitude, sweating, injection site effects, salivation, tail hypertonía
- Must be legally imported into the USA

Uses/Indications

Tiludronate disodium (tiludronic acid) is a bisphosphonate bone resorption inhibitor that is available in some countries for the intravenous treatment of navicular disease in horses. Treatment earlier in the course of the disease apparently results in greater efficacy.

For humans, there is an orally administered FDA-approved product for treating Paget's disease (osteitis deformans).

Pharmacology/Actions

Tiludronate, like other bisphosphonates, inhibit osteoclastic bone resorption by inhibiting osteoclast function after binding to bone hydroxyapatite thereby helping to regulate bone remodeling.

Pharmacokinetics

After intravenous injection in horses the drug is rapidly distributed to bone. Binding is greater to cancellous bone than cortical bone. Plasma protein binding is reported to be approximately 85% and elimination half-life is approximately 4.5 hours. Repeated daily doses do not result in accumulation in plasma. Unbound drug is eliminated unchanged in the urine. Approximately 25–50% of a single IV dose is eliminated in the urine over 96 hours.

Contraindications/Precautions/Warnings

The labeling for *Tildren*® states that the drug should not be used in horses with renal dysfunction or those producing milk for human consumption. Because there is an absence of data on the effects the drug may have on the skeleton of young animals, the manufacturer states to not administer to horses less than 3 years old.

Since the safety of tiludronate has not been studied in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

Use with caution in horses with hypocalcemia or cardiac dysfunction. If used in these patients, slow the rate of injection and watch these patients carefully for the first few hours post-injection.

Adverse Effects

Acute adverse effects reported in horses include colic (reduced appetite, abdominal discomfort, pawing/scratching at ground, restlessness), muscle tremor, fatigue/lassitude and sweating. The incidences of these effects are reported at 5% or less and are postulated to be due to a mild hypoglycemic effect. The onset of colic signs appear within a few hours of treatment and generally resolve without treatment. Should they persist, conventional colic treatments are recommended. Muscle tremors may be treated with intravenous calcium if required.

Up to 9% of patients develop local reactions at the injection site (e.g., phlebitis), particularly after the 4th injection.

Other adverse effects reported include salivation and tail hypertonia.

Reproductive/Nursing Safety

Studies performed in male and female rats at dosages as high as 75mg/kg/day demonstrated no effects on fertility.

Studies in pregnant rabbits given 2X–5X human dosages showed no skeletal abnormalities. Pregnant mice given 7X human dosages showed some adverse effects (decreased litter size, malformed paws in 6 fetuses from one litter). Rat studies have shown decreased litter sizes, but no teratogenic effects. In humans, the FDA categorizes tiludronate as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

As the safety of tiludronate has not been studied in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

Overdosage/Acute Toxicity

Limited information is available. The manufacturer reports that doses of 3X in horses caused an increased frequency of adverse effects, particularly signs of colic and muscle tremor. Intravenous calcium administration may be considered for signs associated with hypocalcemia.

Drug Interactions

■ **CALCIUM- or MAGNESIUM-CONTAINING INTRAVENOUS FLUIDS:** May complex with tiludronate and reduce its availability; do not mix with fluids or administer with fluids such as **Lactated Ringer's**, **Ringer's**, **Plasma-Lyte**®, **Normasol**®, etc.

Laboratory Considerations

No specific concerns were noted.

Doses

■ HORSES:

For navicular disease:

- a) 0.1 mg/kg tiludronic acid slow IV (over 20–30 seconds per 10 mL given) once daily for 10 days. Alternate injection sites from day to day. (Label information; *Tildren*®—Ceva/Sanofi)

Monitoring

- Clinical Efficacy
- Serum Calcium
- Adverse Effects (particularly within first 4 hours after dosing)

Client Information

- This medication should be administered by a veterinary professional
- Patient should be observed for up to 4 hours post-administration for signs of hypocalcemia (muscle tremors, etc.) or colic

Chemistry/Synonyms

Tiludronate disodium is a bisphosphonate that occurs as a white powder having a molecular weight of 380.6. Commercially available products contain the disodium salt of tiludronic acid. 120 mg of tiludronate disodium is equivalent to 100 mg of tiludronic acid.

Tiludronate disodium or tiludronic acid may also be known as ME-3737, SR-41319, acidum tiludronicum, *Tildren*® or *Skelid*®.

Storage/Stability/Compatibility

Unless otherwise indicated, store the unreconstituted powder and diluent at room temperature (15–30°C) in the outer carton.

Shelf life of properly stored unreconstituted product is generally 3 years. Reconstitute the powder by aseptically adding 10 mL of the provided diluent and mix gently. The resulting solution contains 5 mg/mL of tiludronic acid.

After reconstitution, use immediately. Any remaining product should be discarded.

Do not mix or administer with intravenous fluids containing calcium or magnesium (e.g., LRS, Ringer's, etc.).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the USA; it is available in France, Spain, The Netherlands, and Italy as:

Tiludronic Acid: 50 mg (as tiludronate disodium) per vial, with one 10 mL vial of sterile water for reconstitution; *Tildren*® (Sanofi/Ceva). Labeled for use in horses.

Not permitted for use in lactating animals producing milk for human consumption. Labeled meat and offal withdrawal = 0 days. Refer to individual product labels for more information.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

One source recommended for obtaining *Tildren*® via this process is: manorveterinaryexports.com

HUMAN-LABELED PRODUCTS:

Tiludronate Disodium Tablets: 240 mg (equiv. to 200 mg tiludronic acid); *Skelid*® (Sanofi-Synthelabo); (Rx)

Note: The information presented in this monograph pertains to the veterinary-labeled intravenous product only.

TINIDAZOLE

(tye-*ni*-dah-zole) Tindamax®

NITROIMIDAZOLE ANTIPROTOZOAL/
ANTIBIOTIC

Prescriber Highlights

- ▶ Drug similar to metronidazole, potentially useful for treating anaerobic infections (especially in the mouth), trichomoniasis, amebiasis and balantidiasis
- ▶ Little experience in veterinary medicine
- ▶ Adverse effects most likely GI-related, like metronidazole and ronidazole could cause neurotoxicity
- ▶ Many potential drug interactions

Uses/Indications

Little information is presently available on the use of tinidazole in dogs, cats, or horses. It potentially could be useful for treating anaerobic infections, particularly associated with dental infections in small animals. Because of its antiprotozoal effects, it has been used as an alternative for treating giardiasis in small animals, and it could have efficacy against amebiasis, trichomoniasis or balantidiasis in veterinary species, but documentation of efficacy is not available. Tinidazole has a longer duration of action in dogs and cats than does metronidazole.

In humans, oral tinidazole is FDA-approved for treating extraintestinal and intestinal amebiasis, (*Entamoeba histolytica*), giardiasis (*Giardia duodenalis/lamblia*), and trichomoniasis (*T. vaginalis*).

Pharmacology/Actions

Tinidazole is a 5-nitroimidazole similar to metronidazole. It is bactericidal against susceptible bacteria. Its exact mechanism of action is not completely understood, but it is taken-up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible for the drug's antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria.

Tinidazole has activity against many obligate anaerobes and *H. pylori*. It has excellent activity against *Porphyromonas* spp. found in canine gingiva.

Tinidazole is also trichomonacidal and amebicidal. Its mechanism of action for its antiprotozoal activity is not well understood. It has therapeutic activity against *Entamoeba histolytica*, *Trichomonas*, and *Giardia*.

Pharmacokinetics

In dogs and cats, tinidazole is practically completely absorbed after oral administration. Apparent volumes of distribution are 0.66 L/kg in dogs and 0.54 L/kg in cats. Dogs clear the drug about twice as fast as cats; elimination half-lives are about 4.4 hours in dogs, 8.4 hours in cats.

In horses, tinidazole is practically completely absorbed after oral administration. Apparent volume of distribution is 0.66 L/kg an elimination half-life of about 5.2 hours.

Contraindications/Precautions/Warnings

Tinidazole should not be used in patients documented to be hypersensitive to it or other 5-nitroimidazoles (e.g., metronidazole).

Tinidazole is metabolized by the liver; use with caution in patients with hepatic dysfunction.

As other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats and seizures have been reported rarely with tinidazole use in humans, use with caution in animals susceptible to seizures.

The human labeling for tinidazole carries a "black box warning" stating: "Carcinogenicity has been seen in mice and rats treated chronically with another agent in the nitroimidazole class (metronidazole). Although such data have not been reported for tinidazole, avoid unnecessary use of tinidazole. Reserve its use for the conditions for which it is indicated."

Adverse Effects

The adverse effect profiles for dogs, cats or horses are not well described since clinical use of this medication has been limited. Gastrointestinal effects including vomiting, inappetance, and diarrhea are most likely. Giving the medication with food may help alleviate these effects. Other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats; seizures have been reported rarely with tinidazole use in humans.

Tinidazole reportedly is very bitter tasting. If using compounded products, consider using capsules or having a flavored suspension prepared.

Reproductive/Nursing Safety

In studies performed on male rats tinidazole decreased fertility and caused testicular histopathology.

Tinidazole crosses the placenta. While studies in mice and rats have not demonstrated significant fetal effects, because of its mutagenic potential, it is stated that it should not be used in women during the first trimester of pregnancy. In humans, the FDA categorizes tinidazole as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Tinidazole is distributed into maternal milk at levels approximating those found in serum. It is suggested that milk replacer be used if tinidazole is necessary for treating a nursing dam.

Overdosage/Acute Toxicity

Very limited information is available. In studies done in rats and mice, the oral LD₅₀ was >3.6 g/kg for mice and >2 g/kg for rats. Treatment of acute overdoses of tinidazole is symptomatic and supportive. Gastric lavage or induction of emesis may be helpful. Hemodialysis can remove approximately 43% of the amount in the body (human) in a 6 hour session.

Drug Interactions

In humans, the following drug interactions with metronidazole have been reported or are theoretical and may be of significance in veterinary patients receiving tinidazole:

- **ALCOHOL:** May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction
- **CIMETIDINE, KETOCONAZOLE:** May decrease the metabolism of tinidazole and increase the likelihood of dose-related side effects occurring
- **CYCLOSPORINE, TACROLIMUS (systemic):** Tinidazole may increase the serum levels of cyclosporine or tacrolimus
- **FLUOROURACIL (systemic):** Tinidazole may increase the serum levels of fluorouracil and increase the risk of toxicity
- **LITHIUM:** Tinidazole may increase lithium serum levels and increase the risk for lithium toxicity

- **OXYTETRACYCLINE:** Reportedly, may antagonize the therapeutic effects of metronidazole (and presumably tinidazole)
- **PHENOBARBITAL, RIFAMPIN or PHENYTOIN:** May increase the metabolism of tinidazole thereby decreasing blood levels
- **WARFARIN:** Metronidazole (and potentially tinidazole) may prolong the prothrombin time (PT) in patients taking warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

Laboratory Considerations

- **AST, ALT, LDH, Triglycerides, Hexokinase glucose:** Tinidazole, like metronidazole may interfere with enzymatic coupling of the assay to oxidation-reduction of nicotinamide adenine. Falsely low values, including zero, may result.

Doses

- **DOGS:**
 - a) For stomatitis, anaerobic infections: 15–25 mg/kg PO q12h for 7 days. (Greene, Hartmann et al. 2006)
 - b) For giardiasis: 44 mg/kg PO q24h for 6 days. Potentially may be useful for treating trichomoniasis, amebiasis and balantidiasis, but efficacy data lacking for animals. (Barr 2006a)
- **CATS:**
 - a) For stomatitis, anaerobic infections: 15 mg/kg PO q24h for 7 days. (Greene, Hartmann et al. 2006)
- **HORSES:**
 - a) For susceptible anaerobic infections: 10–15 mg/kg PO q12h (Pvorala, Kotilainen et al. 1990)

Monitoring

- Clinical efficacy in treating the infection

Client Information

- Give this medication with food
- Animals should not have access to alcohol when receiving this medication
- If gastrointestinal signs (vomiting, lack of appetite, diarrhea) are severe or persist, contact veterinarian
- Contact veterinarian immediately if animal shows signs of behavior changes, eyes moving back and forth (nystagmus), convulsions, or if patient has difficulty walking, climbing stairs, etc. (ataxia); these could be signs that drug toxicity is occurring

Chemistry/Synonyms

Tinidazole occurs as an almost white or pale yellow, crystalline powder. It is practically insoluble in water, soluble in acetone, and sparingly soluble in methyl alcohol.

Tinidazole may also be known as CP-12574 or tinidazolum. International trade names include: *Estovyn-T*®, *Fasigyn*®, *Tindamax*®, *Tiniba*®, *Tiniameb*®, or *Tinidazol*®.

Storage/Stability

Store tinidazole tablets at controlled room temperature (20–25°C) protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

As tinidazole is a nitroimidazole, its use is prohibited in animals to be used for food.

HUMAN-LABELED PRODUCTS:

Tinidazole Tablets (film-coated): 250 mg, 500 mg; *Tindamax*® (Presutti); (Rx)

TIOPRONIN

(tye-oh-proe-nin) Thiola®, 2-MPG

ANTIUROLITHIC (CYSTINE) AGENT

Prescriber Highlights

- Drug for prevention (& treatment) of cystine urolithiasis
- Cautions: Agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine
- Adverse Effects: Coombs'-positive regenerative spherocyte anemia, aggressiveness, proteinuria, thrombocytopenia, elevations in liver enzymes, dermatologic effects, & myopathy

Uses/Indications

Tiopronin is indicated for the prevention of cystine urolithiasis in patients where dietary therapy combined with urinary alkalization is not completely effective. It may also be useful in combination with urine alkalization to dissolve stones.

Pharmacology/Actions

Tiopronin is considered an antiurolithic agent. It undergoes thiol-disulfide exchange with cystine (cysteine-cysteine disulfide) to form tiopronin-cystine disulfide. This complex is more water-soluble and is readily excreted thereby preventing cystine calculi from forming.

Pharmacokinetics

Tiopronin has a rapid onset of action and in humans, up to 48% of a dose is found in the urine within 4 hours of dosing. Tiopronin has a relatively short duration of action and its effect in humans disappears in about 10 hours. Elimination is primarily via renal routes.

Contraindications/Precautions/Warnings

Tiopronin's risks versus its benefits should be considered before using in patients with agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine.

Adverse Effects

There is limited information available on the adverse effect profile of tiopronin in dogs. While tiopronin is thought to have fewer adverse effects than penicillamine in humans, it has been associated with Coombs'-positive regenerative spherocyte anemia in dogs. Should this effect occur, the drug should be discontinued and appropriate treatment started (corticosteroids, blood component therapy as needed). Other adverse effects noted in dogs include aggressiveness, proteinuria, thrombocytopenia, elevations in liver enzymes, dermatologic effects, and myopathy.

Adverse effects noted in humans that occur more frequently include dermatologic effects (ecchymosis, itching, rashes, mouth ulcers, jaundice) and GI distress; less frequently allergic reactions (specifically adenopathy), arthralgias, dyspnea, fever, hematologic abnormalities, edema, and nephrotic syndrome have been noted.

Reproductive/Nursing Safety

There is limited information on the reproductive safety of tiopronin. Skeletal defects, cleft palates and increased resorptions were noted when rats were given 10 times the human dose of penicillamine and, therefore, may also be of concern with tiopronin. Other animal studies have suggested that tiopronin may affect fetus viability at high doses. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Because tiopronin may be excreted in milk, at present it is not recommended for use in nursing animals.

Overdosage/Acute Toxicity

There is little information available. It is suggested to contact an animal poison control center for further information in the event of an overdose situation.

Drug Interactions

Potentially use of tiopronin with **other drugs causing nephrotoxicity, hepatotoxicity, or bone marrow depression** could cause additive toxic effects. Clinical significance is not clear.

Doses

■ DOGS:

For treatment or prevention of recurrence of cystine urinary calculi:

- In conjunction with an alkalinizing, protein and sodium restricted diet (e.g., *u/d*®), 30–40 mg/kg PO divided into two daily doses. (Cowan 1994)
- Treatment: 20 mg/kg PO twice daily for 1–3 months; relatively high incidence of adverse effects;
Prevention: 15 mg/kg PO twice daily. (Adams and Syme 2005)

Monitoring

- Efficacy (stone size)
- CBC with platelets
- Liver enzymes
- Urinalyses including urine pH

Client Information

- Clients should be counseled on the importance of adequate compliance with this drug to maximize efficacy and detailed on the clinical signs to watch for regarding adverse effects.

Chemistry/Synonyms

A sulfhydryl compound related to penicillamine, tiopronin has a molecular weight of 163.2. It occurs as a white crystalline powder which is freely soluble in water.

Tiopronin may also be known as: SF 522, N-(2-Mercaptopropionyl)-glycine (MPG), 2-MPG, thiopronine, *Acadione*®, *Captimer*®, *Epatiol*®, *Mucolysin*®, *Mucosyt*®, *Sutilan*®, *Thiola*®, *Thiosol*®, or *Tioglis*®.

Storage/Stability

Store tablets at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Tiopronin Tablets: 100 mg; *Thiola*® (Mission); (Rx)

TOBRAMYCIN SULFATE

(toe-bra-mye-sin) Nebcin®, TOBI®

AMINOGLYCOSIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Parenteral aminoglycoside antibiotic that has “good” activity against a variety of bacteria, predominantly gram-negative aerobic bacilli, also in ophthalmic preps
- ▶ Because of potential adverse effects usually reserved for serious infections when given systemically, may be less nephrotoxic than gentamicin
- ▶ Adverse Effects: Nephrotoxicity, ototoxicity, neuromuscular blockade
- ▶ Cats may be more sensitive to toxic effects
- ▶ Risk factors for nephrotoxicity: Preexisting renal disease, age (both neonatal & geriatric), fever, sepsis, & dehydration

Uses/Indications

While most veterinarians use gentamicin or amikacin and there are no approved veterinary tobramycin products in the U.S., tobramycin can be useful clinically to treat serious gram-negative infections in most species. It is often used in settings where gentamicin-resistant bacteria are a clinical problem. The inherent toxicity of the aminoglycosides limit their systemic use to serious infections when there is either a documented lack of susceptibility to other less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Whether tobramycin is less nephrotoxic than either gentamicin or amikacin when used clinically is controversial. Laboratory studies indicate that in a controlled setting in laboratory animals, it may indeed be so.

Pharmacology/Actions

Tobramycin, like the other aminoglycoside antibiotics, act on susceptible bacteria presumably by irreversibly binding to the 30S ribosomal subunit thereby inhibiting protein synthesis. It is considered a bactericidal antibiotic.

Tobramycin's spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *E. coli*, *Klebsiella*, *Proteus*, *Pseudomonas*, *Salmonella*, *Enterobacter*, *Serratia*, *Shigella*, *Mycoplasma*, and *Staphylococcus*.

Antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment.

The aminoglycoside antibiotics are inactive against fungi, viruses and most anaerobic bacteria.

Pharmacokinetics

Tobramycin, like the other aminoglycosides, is not appreciably absorbed after oral or intrauterine administration, but it is absorbed from topical administration (not skin or urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. Subcutaneous injection results in slightly delayed peak levels and more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids, and high levels are found in sputum, bronchial secretions and bile. Aminoglycosides (other than streptomycin) are minimally protein bound (<20%) to plasma proteins. Aminoglycosides do not readily cross the blood-brain barrier nor penetrate ocular tissue. CSF levels are unpredictable and range from 0–50% those found in the serum. Therapeutic levels are found in bone, heart, gallbladder and lung tissues after parenteral dosing. Aminoglycosides tend to accumulate in certain tissues such as the inner ear and kidneys, which may help explain their toxicity. Aminoglycosides cross the placenta and fetal concentrations range from 15–50% those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

Contraindications/Precautions/Warnings

Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections, there are no other absolute contraindications to their use; however, they should be used with extreme caution in patients with preexisting renal disease with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis, and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs (e.g., “seeing-eye”, herding, dogs for the hearing impaired, etc.).

Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are generally considered contraindicated in rabbits/hares as they adversely affect the GI flora balance in these animals.

Adverse Effects

The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity normally manifests by increases in BUN, creatinine, nonprotein nitrogen in the serum and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest with either auditory and/or vestibular clinical signs and may be irreversible. Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but either form can occur with any of the drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain or inflammation at the injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs, hematologic, and hepatic effects have been reported.

Reproductive/Nursing Safety

Tobramycin can cross the placenta and concentrate in fetal kidneys and while rare, cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Total irreversible deafness has been reported in some human babies whose mothers received tobramycin during pregnancy. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Small amounts of aminoglycoside antibiotics are excreted in milk, but are unlikely to cause clinically significant effects in nursing offspring.

Overdosage/Acute Toxicity

Should an inadvertent overdosage be administered, three treatments have been recommended: 1) Hemodialysis is very effective in reducing serum levels of the drug, but is not a viable option for most veterinary patients; 2) Peritoneal dialysis also will reduce serum levels, but is much less efficacious; 3) Complexation of drug with either carbenicillin or ticarcillin (12–20 g/day in humans) is reportedly nearly as effective as hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tobramycin and may be of significance in veterinary patients:

- **BETA-LACTAM ANTIBIOTICS (penicillins, cephalosporins):** May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides *in vitro* (do not mix together) and *in vivo* (patients in renal failure)
- **CEPHALOSPORINS:** The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).
- **DIURETICS, LOOP (e.g., furosemide, torsemide) or OSMOTIC (e.g., mannitol):** Concurrent use with loop or osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides
- **NEPHROTOXIC DRUGS, OTHER (e.g., cisplatin, amphotericin B, polymyxin B, or vancomycin):** Potential for increased risk for nephrotoxicity
- **NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL:** Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

Laboratory Considerations

- Tobramycin serum concentrations may be falsely decreased if the patient is also receiving **beta-lactam antibiotics** and the serum is stored prior analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough level.

Doses

Note: There is significant inter-patient variability with aminoglycoside pharmacokinetic parameters. To insure therapeutic levels and to minimize the risks for toxicity development, consider monitoring serum levels for this drug. Like other aminoglycosides, most now recommend dosing mammals once daily; consider giving the total daily dose as a single dose (e.g., if dose listed is 2 mg/kg q8h, give 6 mg/kg once daily).

■ DOGS & CATS:

For small animals, one pair of authors (Aronson and Aucoin 1989) make the following recommendations with regard to minimizing risks of toxicity, yet maximizing efficacy:

- 1) Dose according to animal size. The larger the animal, the smaller the dose (on a mg/kg basis).
- 2) The more risk factors (age, fever, sepsis, renal disease, dehydration) the smaller the dose.
- 3) In old patients or those suspected of renal disease, increase dosing interval from q8h to q16–24h.
- 4) Determine serum creatinine prior to therapy and adjust by changes in level even if it remains in “normal range.”
- 5) Monitor urine for changes in sediment (e.g., casts) or concentrating ability. Not very useful in patients with UTI.
- 6) Therapeutic drug monitoring is recommended when possible.
 - a) 2 mg/kg IV, IM, or SC q8h (avoid use or reduce dosage in patients with renal failure; recommend therapeutic drug monitoring, particularly in young animals) (Vaden and Papich 1995)
 - b) For susceptible UTI: 1–2 mg/kg SC q8h (Brovida 2003)
 - c) For sepsis: 2–4 mg/kg IV three times daily (q8h) (Tello 2003b)
 - d) Dogs:

For soft tissue, systemic infections: 1–1.7 mg/kg IV q8h or 3–5.1 mg/kg IV q24h for less than 7 days;

For systemic infections: 2 mg/kg SC q8–12h or 4–6 mg/kg SC q24h for less than 7 days;

For persistent bacteremia: 3–5 mg/kg IV, IM, SC q8h or 9–15 mg/kg IV, IM or SC q24h for 7 days or less. (Greene, Hartmann et al. 2006)
 - e) Cats:

For soft tissue, systemic infections: 2 mg/kg IV, IM or SC q12h or 4 mg/kg IV, IM, SC q24h for 5 days or less;

For persistent bacteremia: 2 mg/kg IV, IM, SC q8h or 6 mg/kg IV, IM or SC q24h for 5 days or less.

(Greene, Hartmann et al. 2006)

■ HORSES:

For susceptible infections:

- a) 1–1.7 mg/kg q8h IV (slowly) or IM (**Note:** This is a human dose and should be used as a general guideline only) (Walker 1992)

■ LLAMAS:

For susceptible infections:

- a) 4 mg/kg IV q24h; 0.75 mg/kg IV q8h (Baird 2003)

■ BIRDS:

For susceptible infections:

- a) 5 mg/kg IM every 12 hours (Bauck and Hoefer 1993)
- b) 2.5–5 mg/kg/day; must be given parenterally (Flammer 2003b)

■ REPTILES:

For susceptible infections:

- a) 2.5 mg/kg once daily IM (Gauvin 1993)

Monitoring

- Efficacy (cultures, clinical signs associated with infection)
- Renal toxicity; baseline urinalysis, and serum creatinine/BUN. Casts in the urine are often the initial sign of impending nephrotoxicity. Frequency of monitoring during therapy is controversial, but daily urinalysis and serum creatinine may not be too frequent.
- Gross monitoring of vestibular or auditory toxicity is recommended
- Serum levels if possible

Client Information

- With appropriate training, owners may give subcutaneous injections at home, but routine monitoring of therapy for efficacy and toxicity must still be done
- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication

Chemistry/Synonyms

An aminoglycoside derived from *Streptomyces tenebrarius*, tobramycin occurs as a white to off-white, hygroscopic powder that is freely soluble in water and very slightly soluble in alcohol. The sulfate salt is formed during the manufacturing process. The commercial injection is a clear, colorless solution and the pH is adjusted to 6–8 with sulfuric acid and/or sodium hydroxide.

Tobramycin Sulfate may also be known as: tobramycin sulphate, *Brulamycin*®, *Gernebcin*®, *Mytobrin*®, *Nebcina*®, *Nebcine*®, *Nebicina*®, *Obracin*®, *Tobra*®, *Tobra Gobens*®, *TOBI*®, *Tobra Laf*®, *Tobra-cell*®, *Tobracil*®, *Tobradistin*®, *Tobramina*®, *Tobraneg*®, *Tobrasix*®, *Tobrex*®, *Tomycin*®, or *Trazil*®.

Storage/Stability/Compatibility

Tobramycin sulfate for injection should be stored at room temperature (15–30°C); avoid freezing and temperatures above 40°C. Do not use the product if discolored.

While the manufacturers state that tobramycin should not be mixed with other drugs, it is reportedly physically **compatible** and stable in most commonly used intravenous solutions (not compatible with dextrose and alcohol solutions, Polysal, Polysal M, or Isolyte E, M or P) and **compatible** with the following drugs: aztreonam, bleomycin sulfate, calcium gluconate, cefoxitin sodium, ciprofloxacin lactate, clindamycin phosphate (not in syringes), floxacillin sodium, metronidazole (with or without sodium bicarbonate), ranitidine HCl, and verapamil HCl.

The following drugs or solutions are reportedly physically **incompatible** or only compatible in specific situations with tobramycin: cefamandole nafate, furosemide and heparin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

In vitro inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented; see the information in the Drug Interaction and Laboratory Consideration sections.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Tobramycin Sulfate Injection: 0.8 mg/mL and 1.2 mg/mL (as sulfate) in 100 mL & 50 mL single-dose containers; 10 mg/mL in 2 mL vials; and 40 mg/mL in 1.5 mL and 2 mL syringes, 2 mL and 30 mL vials; Tobramycin in 0.9% Sodium Chloride (Hospira); generic (various); (Rx)

Tobramycin Sulfate Powder for Injection: 1.2 g vials (40 mg/mL after reconstitution), preservative free in 50 mL bulk package vial; generic (American Pharmaceutical Partners); (Rx)

Tobramycin Nebulizer Solution: 60 mg/mL in 5 mL amps; *TOBI*® (PathoGenesis); (Rx)

Also available in ophthalmic preparations.

TOCAINIDE HCL**(toe-kay-nide) Tonocard®****ORAL ANTIARRHYTHMIC****Prescriber Highlights**

- ▶ Oral antiarrhythmic with similar activity as lidocaine; not commonly used in veterinary medicine
- ▶ **Contraindications:** Hypersensitivity reactions to it or amide-type local anesthetics, 2nd or 3rd degree AV block & not being artificially paced. **Caution:** Heart failure, hematologic abnormalities, or preexisting bone marrow failure.
- ▶ **Adverse Effects:** CNS effects (depression, ataxia, muscle tremors, etc.), nausea & vomiting (usually transient), cardiovascular effects (hypotension, bradycardia, tachycardia, other arrhythmias, & exacerbation of CHF)
- ▶ Case reports of dogs on long-term therapy (>3 mos.) developing ocular & renal toxicity

Uses/Indications

Veterinary experience with tocainide is limited. At this time, dogs are the only veterinary species where enough clinical experience has been garnered to recommend its use. It is indicated for the oral therapy of ventricular arrhythmias, principally ventricular tachycardia and ventricular premature complexes. In humans, response to lidocaine can usually predict whether tocainide might be effective.

Pharmacology/Actions

Tocainide is considered a class I_B (membrane-stabilizing) antidysrhythmic agent that demonstrates rapid rates of attachment and dissociation to sodium channels. Like lidocaine, tocainide produces a dose-dependent decrease in potassium and sodium conductance that results in decreased excitability of myocardial cells. Automaticity, conduction velocity, and effective refractory periods are decreased at therapeutic levels. Little or no increases in PR intervals, QRS complexes, or QT intervals are seen at therapeutic levels. Like lidocaine, tocainide has little, if any effect, on autonomic tone.

Pharmacokinetics

Following oral administration, tocainide is rapidly and almost completely absorbed. The presence of food in the stomach may alter the rate, but not the extent, of absorption. Unlike lidocaine, the

hepatic first-pass effect is minimal with tocainide. In humans, peak plasma levels occur between 0.5–2 hours when administered on an empty stomach.

The distribution aspects of tocainide have not been fully described. In humans, the volume of distribution ranges from 1.5–4 L/kg and has been reported to be 1.7 L/kg in dogs. Tocainide is minimally bound to plasma proteins. It is unknown if it crosses the placenta or enters into the milk.

Tocainide is metabolized by the liver, but up to 50% of a dose is excreted unchanged by the kidneys into the urine. Alkalinization of the urine may result in a substantial decrease in the amount of tocainide that is excreted unchanged into the urine, but acidification of the urine reportedly does not enhance the excretion rate. Elimination half-life is dose-dependent and at the clinical doses used for dogs, not well-described.

Contraindications/Precautions/Warnings

Tocainide is contraindicated in patients who have demonstrated previous hypersensitivity reactions to it or amide-type local anesthetics, or who have 2nd or 3rd degree AV block and are not being artificially paced.

Use tocainide cautiously in patients with heart failure as it has the potential to aggravate the condition. Use with caution in patients with hematologic abnormalities or preexisting bone marrow failure.

Adverse Effects

It is expected that tocainide would exhibit a similar adverse reaction profile as lidocaine with anorexia, and vomiting being most likely. In dogs, tocainide serum concentrations of greater than 12 mcg/mL have been associated with neurotoxicity (ataxia, head tremor). There are case reports of dogs receiving tocainide for more than 3 months developing ocular (corneal dystrophy) and renal toxicity.

Although side effects are common in human patients, they are usually dose related, mild, and reversible upon discontinuation of the drug. CNS effects can include drowsiness, depression, ataxia, muscle tremors, etc. Nausea and vomiting may occur, but are usually transient. Cardiovascular effects reported include hypotension, bradycardia, tachycardia, other arrhythmias, and exacerbation of CHF. Rarely (<1% incidence), clinical signs of bone marrow depression or pulmonary effects (pulmonary fibrosis, pneumonia, respiratory arrest, pulmonary edema, etc.) have been reported in humans.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Tocainide enters milk in significant quantities and may potentially cause adverse effects in nursing offspring.

Overdosage/Acute Toxicity

Dogs tend to be rather resistant to the acute toxic effects of the drug. In one study, dogs were administered 750 mg/kg over 6 hours and emesis was the only frequent effect seen, but ECG changes were also seen in some animals.

There is no specific antidote for tocainide overdose and treatment tends to be supportive and symptomatic. For more information, see the Lidocaine monograph. Tocainide can be removed with hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tocainide and may be of significance in veterinary patients:

- **ANTIARRHYTHMICS, OTHER CLASS IB** (e.g., lidocaine, phenytoin, mexiletine): Toxicities may be additive, with little or no therapeutic gain, if tocainide is used concurrently with other Class IB anti-dysrhythmics; use caution, when converting from one Class IB agent to another
- **CIMETIDINE (and other H2 blockers)**: May reduce tocainide bio-availability
- **METOPROLOL**: Tocainide used concomitantly with metoprolol (a beta-adrenergic antagonist) can have additive effects on cardiac index and wedge pressure; may clinically significant, particularly in patients with sick sinus syndrome and impaired AV conduction
- **RIFAMPIN**: May decrease tocainide effects by increasing metabolism

Doses

- **DOGS**:
 - a) 10–20 mg/kg (up to 25 mg/kg) PO q8h (Ware 2000)
 - b) 5–10 mg/kg PO three times daily (Atkins 2003a)
 - c) 10–20 mg/kg PO q8h (Fox 2003a)
 - d) 10–20 mg/kg PO two to three times a day (Tilley 2007)

Monitoring

- ECG
- Clinical signs of toxicity (see Adverse Reactions); may wish to monitor CBC's if treating chronically (**Note**: For human patients, the manufacturer recommends weekly CBC's with differential and platelets, be run at weekly intervals for the first 3 months of therapy and periodically thereafter)
- Serum levels (therapeutic levels in humans are usually 3–10 micrograms/mL), especially if clinical signs of toxicity or lack of efficacy are noted.

Client Information

- To be effective, the animal must receive all doses as prescribed
- Notify veterinarian if the animal exhibits any abnormal bleeding or bruising, develops wheezing, shortness of breath, or a cough
- If dog vomits or becomes anorexic after dosing, give with food; if vomiting persists or animal develops a change in behavior or attitude, contact veterinarian

Chemistry/Synonyms

An amide-type local anesthetic, tocainide HCl occurs as a bitter tasting, white, crystalline powder with a pK_a of 7.8. It is freely soluble in both water and alcohol. Tocainide is structurally related to lidocaine, but it is a primary amine where lidocaine is a tertiary amine. This modification allows tocainide to be resistant to extensive first-pass metabolism after oral administration.

Tocainide HCl may also be known as W-36095, *Tonocard*® or *Xylotocan*®.

Storage/Stability

Protect tablets from light and store in well-closed containers. An expiration date of 4 years after manufacture is assigned to the commercially available tablets when packaged in high-density polyethylene bottles.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Tocainide HCl Oral Tablets: 400 mg, 600 mg; *Tonocard*® (Astra Merck); (Rx)

TOLAZOLINE HCL

(toe-laz-oh-leen) Tolazine®

ALPHA-ADRENERGIC BLOCKER

Prescriber Highlights

- Alpha-adrenergic blocker used primarily as a reversal agent for xylazine
- **Contraindications:** Horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia or shock, hypersensitivity, or with coronary artery or cerebrovascular disease
- **Adverse Effects: HORSES:** Transient tachycardia; peripheral vasodilatation presenting as sweating & injected mucous membranes of the gingiva & conjunctiva; hyperalgesia of the lips (licking, flipping of lips); piloerection; clear lacrimal & nasal discharge; muscle fasciculations; apprehensiveness

Uses/Indications

Tolazoline is approved and indicated for the reversal of effects associated with xylazine in horses. It has also been used for this purpose in a variety of other species as well, but less safety and efficacy data is available.

In humans, the primary uses for tolazoline are: treatment of persistent pulmonary hypertension in newborns, adjunctive treatment and diagnosis of peripheral vasospastic disorders, and as a provocative test for glaucoma after subconjunctival injection.

Pharmacology/Actions

By directly relaxing vascular smooth muscle, tolazoline has peripheral vasodilating effects and decreases total peripheral resistance. Tolazoline also is a competitive α_1 and α_2 -adrenergic blocking agent, explaining its mechanism for reversing the effects of xylazine. Tolazoline is rapid acting (usually within 5 minutes of IV administration), but has a short duration of action and repeat doses may be required.

Pharmacokinetics

After IV injection in horses, tolazoline is widely distributed. Animal studies have demonstrated that tolazoline is concentrated in the liver and kidneys. Half-life in horses at recommended doses is approximately 1 hour.

Contraindications/Precautions/Warnings

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established and some believe it should not be used in foals, as adverse reactions and fatalities have been reported.

Tolazoline should be considered contraindicated in patients known to be hypersensitive to it, or with coronary artery or cerebrovascular disease. Humans having any of the above-contraindicated conditions should use extra caution when handling the agent.

Adverse Effects

In horses adverse effects that may occur include: transient tachycardia; peripheral vasodilatation presenting as sweating and injected mucous membranes of the gingiva and conjunctiva; hyperalgesia of the lips (licking, flipping of lips); piloerection; clear lacrimal and nasal discharge; muscle fasciculations; apprehensiveness. Adverse effects should diminish with time and generally disappear within 2 hours of dosing. The potential for adverse effects increases if tolazoline is given at higher than recommended dosages or if xylazine has not been previously administered.

Reproductive/Nursing Safety

Safety during pregnancy, in breeding or lactating animals has not been established. It is unknown if the drug enters maternal milk.

Overdosage/Acute Toxicity

In horses given tolazoline alone (no previous xylazine), doses of 5X recommended resulted in gastrointestinal hypermotility with resultant flatulence and defecation or attempt to defecate. Some horses exhibited mild colic and transient diarrhea. Intraventricular conduction may be slowed when horses are overdosed, with a prolongation of the QRS-complex noted. Ventricular arrhythmias may occur resulting in death with higher overdoses (5X). In humans, ephedrine (NOT epinephrine or norepinephrine) has been recommended to treat serious tolazoline-induced hypotension.

A llama that received 4.3 mg/kg IV and again 45 minutes later (approximately a 5X overdose) developed signs of anxiety, hyperesthesia, profuse salivation, GI tract hypermotility, diarrhea, convulsions, hypotension, and tachypnea. Treatment including IV diazepam, phenylephrine, IV fluids, and oxygen was successful. (Reed, Duke et al. 2000).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolazoline and may be of significance in veterinary patients:

- **ALCOHOL:** Accumulation of acetaldehyde can occur if tolazoline and alcohol are given simultaneously
- **EPINEPHRINE, NOREPINEPHRINE:** If large doses of tolazoline are given with either norepinephrine or epinephrine, a paradoxical drop in blood pressure can occur followed by a precipitous increase in blood pressure

Doses**■ HORSES:**

For reversal of xylazine effects:

- a) 4 mg/kg slow IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; *Tolazine*®—Lloyd Laboratories)

■ DOGS & CATS:

For reversal of xylazine effects:

- a) 4 mg/kg slow IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; *Tolazine*®—Lloyd Laboratories; New Zealand)

Note: If reversal is warranted, the high concentration (100 mg/mL) of the veterinary drug may make accurate dosing difficult; yohimbine or the human-labeled tolazoline product (25 mg/mL) may be safer alternatives than *Tolazine*® (100 mg/mL). **Note:** Tolazoline is not approved for use in dogs and cats in the USA and the US manufacturer does not recommend its use

■ LLAMAS/ALPACAS:

For reversal of xylazine/ketamine effects:

- a) 2 mg/kg IM (DuBois, Prado et al. 2004)
- b) 1–2 mg/kg IV or IM; Caution: acute death has been reported after rapid IV administration of tolazoline at high dosages. (Anderson 2005)

■ BIRDS:

As a reversal agent for alpha2-adrenergic agonists (e.g., xylazine, detomidine, etc.):

- a) 15 mg/kg IV (Clyde and Paul-Murphy 2000)

■ DEER:

Note: Not approved in the USA for use in food animals

For reversal of xylazine effects:

- a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)

■ CATTLE:

Note: Not approved in the USA for use in food animals

For reversal of xylazine effects:

- a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)

■ SHEEP & GOATS:

Note: Not approved in the USA for use in food animals

For reversal of xylazine effects:

- a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)
- b) Goats: 1–2 mg/kg IV, inject slowly to effect (Hooper 2002)
- c) Sheep: 2.2 mg/kg slowly IV. (Snyder 2006)

Monitoring/Client Information

- Reversal effects (efficacy)
- Adverse effects (see above). Because of the risks associated with the use of xylazine and reversal by tolazoline, these drugs should be administered and monitored by veterinary professionals only.

Chemistry/Synonyms

An alpha-adrenergic blocking agent, tolazoline HCl is structurally related to phentolamine. It occurs as a white to off-white, crystalline powder possessing a bitter taste and a slight aromatic odor. Tolazoline is freely soluble in ethanol or water. The commercially available (human) injection has pH between 3–4.

Tolazoline HCl may also be known as: benzazoline hydrochloride, tolazolinium chloratum, *Prisco*®, *Priscoline*®, *Tolazine*® or *Vaso-Dilatan*®.

Storage/Stability/Compatibility

Commercially available injection products should be stored between 15–30°C and protected from light. The drug is reportedly physically **compatible** with the commonly used IV solutions.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Tolazoline HCl Injection: 100 mg/mL in 100 mL multi-dose vials; *Tolazine*® (Lloyd); (Rx). Approved for use in horses; not to be used in food-producing animals.

HUMAN-LABELED PRODUCTS: None

TOLFENAMIC ACID

(tole-fen-a-mik) Tolfedine®

NONSTEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- ▶ NSAID approved for dogs & cats in Canada, Europe
- ▶ Available (not in USA) in both oral & injectable dosage forms
- ▶ Relatively safe for short-term use

Uses/Indications

Tolfenamic acid may be useful for the treatment of acute or chronic pain and/or inflammation in dogs and acute pain/inflammation in cats. In Europe, it is also approved for use in cattle.

Pharmacology/Actions

Tolfenamic acid exhibits pharmacologic actions similar to those of aspirin. It is a potent inhibitor of cyclooxygenase, thereby inhibiting the release of prostaglandins. It also has direct inhibition of prostaglandin receptors. Tolfenamic acid has significant anti-thromboxane activity and is not recommended for use pre-surgically because of its effects on platelet function.

Pharmacokinetics

Tolfenamic acid is absorbed after oral administration. In dogs, peak levels occur from 2–4 hours after dosing. Enterohepatic recirculation is increased if given with food. This can increase the bioavailability, but also creates more variability in bioavailability than when given to fasted dogs. The volume of distribution in dogs is reported to be 1.2 L/kg and it has an elimination half-life of about 6.5 hours. Duration of antiinflammatory effect is 24–36 hours.

Contraindications/Precautions/Warnings

Tolfenamic acid is contraindicated in animals hypersensitive to it or to other drugs in its class (*i.e.*, meclofenamic acid). Like other NSAIDs, it should not be used in animals with active GI bleeding or ulceration. Use with caution in patients with decreased renal or hepatic function.

Adverse Effects

Tolfenamic acid is relatively safe when given as recommended in dogs and cats. Vomiting and diarrhea have been reported after oral use. Experimental studies did not demonstrate significant renal or GI toxicity until doses were more than 10 times labeled.

Because of its anti-thromboxane activity and resultant effects on platelet function, tolfenamic acid is not recommended for use pre-surgically.

Reproductive/Nursing Safety

No specific information was located; like other NSAIDs, tolfenamic acid should be used with caution in pregnancy.

Overdosage/Acute Toxicity

No specific information was located. It is suggested that if an acute, overdose occurs treatment follows standard overdose procedures (empty gut following oral ingestion, etc.). Supportive treatment should be instituted as necessary and IV diazepam used to help control seizures. Monitor for GI bleeding. Because tolfenamic acid may cause renal effects, monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolfenamic acid or other NSAIDs and may be of significance in veterinary patients:

- **ASPIRIN:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS:** As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tolfenamic acid
- **DIGOXIN:** NSAIDs may increase serum levels
- **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans and potentially could also affect tolfenamic acid levels in dogs
- **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS** (*e.g.*, furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **WARFARIN:** Closely monitor patients also receiving drugs that are highly bound to plasma proteins (*e.g.*, warfarin), as tolfenamic acid and its active metabolite are 98–99% protein bound in the dog

Doses

■ DOGS:

- a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days.

For chronic pain: 4 mg/kg, PO once daily for 3–5 consecutive days per week. The injectable is suggested for the first dose only. (Dowling 2000)

- b) First dose: 4 mg/kg SC or IM; follow with tablets at 4 mg/kg PO once daily for 2–4 days. The treatment may be repeated once a week as required, or as recommended by the veterinarian, PO once daily for 3–5 days. (Label information; *Tolfedine*®—Vetoquinol Canada)

■ CATS:

- a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days. The injectable is suggested for the first dose only. (Dowling 2000)
- b) 4 mg/kg PO once daily for 3–5 days or as recommended by the veterinarian. (Label information; *Tolfedine*®—Vetoquinol Canada)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- The weekly dosing regimen (3–5 consecutive days per week for dogs) is important to follow to minimize risks of adverse effects
- Report any changes in appetite, water consumption, or GI distress to veterinarian

Chemistry/Synonyms

A non-steroidal antiinflammatory agent in the anthranilic acid (fenamate) category, tolfenamic acid is related chemically to meclofenamic acid.

Tolfenamic Acid may also be known as: acidum tolfenamicum, *Bifenac*®, *Clotam*®, *Clotan*®, *Fenamic*®, *Flocur*®, *Gantil*®, *Migea*®, *Polmonin*®, *Purfalox*®, *Rociclyn*®, *Tolfamic*®, *Tolfedine*® or *Turbaund*®.

Storage/Stability

Unless otherwise labeled, store tolfenamic acid tablets and solution at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA.

In Canada and Europe: Tolfenamic Acid Tablets: 6 mg, 30 mg, 60 mg and Tolfenamic Acid Injection 40 mg/mL are available. Common trade name is *Tolfedine*® (Vetoquinol).

HUMAN-LABELED PRODUCTS: None in the USA

TOLTRAZURIL

(tole-*traz*-yoo-ri) Baycox®

ANTIPROTOZOAL/ANTICOCCIDIAL

Prescriber Highlights

- ▶ Antiprotozoal labeled for treating coccidia in poultry (in Europe)
- ▶ May be considered as an alternative for treating coccidiosis in dogs & cats, oocyst shedding stage of toxoplasmosis in cats, etc.
- ▶ Not commercially available in the USA, must be legally imported
- ▶ Adverse effect profile not well described

Uses/Indications

Toltrazuril is an antiprotozoal agent that may be considered as an alternative treatment for coccidiosis in dogs and cats, Hepatozoon infections, or for treating the oocyst shedding stage of toxoplasmosis in cats. It has also been used as a treatment for overwhelming parasitic loads in lizards (Bearded Dragons).

Toltrazuril has activity against parasites of the genus *Hepatozoon*, but other drugs (e.g., imidocarb, primaquine, doxycycline) are generally used.

While toltrazuril has been used to treat equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*, use of approved products now available (e.g., nitazoxanide, ponazuril, pyrimethamine/sulfadiazine) is preferred.

Toltrazuril has been used in some countries to treat *Isospora suis* in piglets.

Pharmacology/Actions

Toltrazuril is the parent compound to ponazuril (toltrazuril sulfone). Its mechanism of action is not well understood, but it appears to inhibit protozoal enzyme systems.

Toltrazuril has activity against *Hepatozoon*, *Isospora*, *Sarcocystis*, *Toxoplasma*, and all intracellular stages of coccidia.

Pharmacokinetics

Little information is available. Toltrazuril is about 50% absorbed after oral consumption in poultry. Highest concentrations are found in the liver; it is rapidly metabolized into the sulfone derivative (ponazuril).

Contraindications/Precautions/Warnings

Toltrazuril should not be used in patients who have had prior hypersensitivity reactions to it or other triazinone (triazine) antiprotozoals (e.g., ponazuril, diclazuril).

The principle metabolite of toltrazuril reportedly persists in the environment and can contaminate groundwater, however there appears to be little risk for significant environmental contamination when toltrazuril is used in dogs, cats, horses, or other companion animals (pet birds, reptiles).

Adverse Effects

Toltrazuril appears to be well tolerated in birds. An adverse effect profile in mammals is not well described. Potentially, GI signs could occur. Some horses receiving the related drug ponazuril, developed blisters on their nose and mouth, and some, a rash or hives during field trials.

Reproductive/Nursing Safety

No reproductive or nursing safety information was located; weigh potential risks versus benefits of use during pregnancy or lactation.

Overdosage/Acute Toxicity

Very limited information is available. Doses of up to 10x in horses were tolerated without significant adverse effects. 5x overdoses in poultry have been tolerated without clinical signs noted. Decreased water intake has been seen if overdoses are greater than 5X.

Drug Interactions

None reported

Laboratory Considerations

No issues were noted.

Doses

■ DOGS:

- a) For coccidiosis (Cystoisosporosis): 10–20 mg/kg PO one time to all puppies at 3–4 weeks of age will help prevent problems associated with intestinal coccidiosis (Dauguschies, Mundt et al. 2000)
- b) For coccidiosis: 15 mg/kg PO once daily for 3–6 days (Dubey and Greene 2006)

■ CATS:

- a) For enteroepithelial cycle of toxoplasmosis (oocyst shedding): 5–10 mg/kg PO once daily for 2 days (Dubey and Lappin 2006)
- b) For coccidiosis: 30 mg/kg PO once daily for 2–3 days (Greene, Hartmann et al. 2006)

■ BIRDS:

- a) For coccidiosis in raptors: 7 mg/kg PO once daily for 2–3 days (Jones 2004b)

■ REPTILES:

- a) For parasitism in Bearded Dragons: 5–15 mg/kg PO once daily for 3 days (Kramer 2006)

Monitoring

- Clinical efficacy

Client Information

- Avoid direct contact with this medication; the manufacturer recommends wearing synthetic rubber gloves when handling the 2.5% solution. Wash exposed skin after use.

Chemistry/Synonyms

Related to other antiprotozoals such as ponazuril, toltrazuril is a triazinone (triazine) antiprotozoal (anticoccidial) agent. The commercially available (in Europe) 2.5% oral solution is an alkaline, clear, colorless to yellow brown solution which also contains triethanolamine 30 mg/mL and polyethylene glycol 80.7 mg/mL. Toltrazuril has a molecular weight of 425.4

Toltrazuril may also be known as Bay-Vi-9142, toltrazurilo, toltrazurilum and *Baycox*®.

Storage/Stability

The 2.5% solution should be stored at temperatures at 25°C or below.

Dilutions in drinking water more concentrated than 1:1000 (1 mL of the 2.5% solution to 1 liter of water) may precipitate. After dilution, the resulting solution is stable for 24 hours. It is recommended that medicated drinking water not consumed after 24 hours be discarded.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA

In some European countries: Toltrazuril 2.5% (25 mg/mL) solution for dilution in drinking water in 1 liter bottles; *Baycox*® 2.5% Solution (Bayer); (Rx). Approved for treatment of coccidiosis in poultry. In the UK, slaughter withdrawal is 18 days for poultry. Not for use in birds producing eggs for human consumption.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

HUMAN-LABELED PRODUCTS: None

TOPIRAMATE

(toe-*pie*-rah-mate) Topamax®

ANTICONVULSANT

Prescriber Highlights

- ▶ Antiseizure medication that may be useful for seizure disorders in dogs, particularly partial seizure activity; may be of benefit in treating cats, but little information available
- ▶ Very short half-life in dogs (2–4 hours), but therapeutic activity may persist secondary to high affinity for receptors in brain
- ▶ Adverse effect profile may include GI distress, inappetance, & irritability in dogs; in cats, sedation & inappetance have been noted
- ▶ Expense may be an issue; generics now available

Uses/Indications

Topiramate may be useful for treating seizures in dogs, particularly partial seizure activity. It may also be of benefit in treating cats, but little information is available.

Pharmacology/Actions

While the exact mechanism for its antiseizure action is not known, topiramate possesses three properties that probably play a role in its activity: Topiramate blocks in a time-dependent manner action potentials elicited repetitively by a sustained depolarization of neurons; it increases the frequency that GABA activates GABA_A receptors; and it antagonizes the kainite/AMPA receptors without affecting the NMDA receptor subtype. Topiramate's actions are concentration-dependent; effects can first be seen at 1 microMole and maximize at 200 microMoles. Topiramate is a weak inhibitor of carbonic anhydrase isoenzymes CA-II and CA-IV, but it is believed that this effect does not contribute significantly to its antiepileptic actions.

Pharmacokinetics

In dogs, topiramate is rapidly absorbed after oral administration, but absolute bioavailability varies between 30–60%. Half-life ranges from 2–4 hours after multiple doses. Comparatively, the half-life in humans is about 21 hours in adults, but shorter in children. In humans, the drug is not extensively metabolized and about 70% is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Topiramate is contraindicated in patients hypersensitive to it. It should be used with caution (in humans) with impaired hepatic or renal function.

Adverse Effects

Because this drug rarely has been used in veterinary patients, an accurate adverse effect profile is not known. In dogs, most prevalent adverse effects reported include GI distress, inappetance, and irritability. In cats, sedation and inappetance have been noted.

In humans, the most likely adverse effects include somnolence, dizziness, nervousness, confusion, and ataxia. Very rarely, acute myopia with secondary angle closure glaucoma has been reported. Incidence of kidney stones is about 2–4 times higher in patients taking topiramate than in the general population.

Reproductive/Nursing Safety

In humans, the FDA categorizes topiramate as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Teratogenic effects were noted in mice and rats given topiramate at dosages equivalent to those used in humans.

Topiramate enters maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity

There were 132 exposures to topiramate reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 113 were dogs with 10 showing clinical signs and 19 were cats with 4 showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, lethargy, anxiety, disorientation and head shaking. Common findings in cats recorded in decreasing frequency included vomiting, ataxia and lethargy.

Overdoses in humans have caused convulsions, drowsiness/lethargy, slurred speech, blurred and double vision, impaired mentation/stupor, ataxia, metabolic acidosis, hypotension, agitation, and abdominal pain.

Treatment consists of gut emptying protocols if the ingestion was recent, and supportive therapy. Hemodialysis is effective in enhancing the elimination of topiramate from the body.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving topiramate and may be of significance in veterinary patients:

- **AMITRIPTYLINE:** Topiramate may increase levels
- **CARBONIC ANHYDRASE INHIBITORS** (acetazolamide, dichlorphenamide, etc.): Used concomitantly with topiramate, may increase the risk of renal stone formation
- **CNS DEPRESSANT DRUGS, OTHER:** Other CNS depressant drugs may exacerbate the adverse effects of topiramate
- **LAMOTRIGINE:** May increase topiramate levels
- **PHENYTOIN:** May decrease topiramate levels; phenytoin levels may increase
- **VALPROIC ACID:** May decrease topiramate and VPA levels

Laboratory Considerations

No specific laboratory interactions or considerations were noted. Plasma concentrations of topiramate are usually not monitored in human patients, but therapeutic levels are thought to range from 2–25 mg/L.

Doses

- **DOGS:**
 - a) As an alternative second line anticonvulsant: 5–10 mg/kg PO q12h (Shell 2003c)
 - b) As an alternative treatment for refractory generalized and focal seizures: 5–10 mg/kg PO twice daily (Smith 2002b)
 - c) Initial dose of 2–10 mg/kg PO q12h. (Podell 2006a)
 - d) 5–10 mg/kg PO twice daily; start at the lower dosage to reduce adverse effects. (Kortz 2005)
- **CATS:**
 - a) 12.5–25 mg PO (total dose) q8–12h. (Podell 2006a)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Clients must understand that the clinical use of this agent is relatively “investigational” in veterinary patients, that it must be dosed often in dogs, and the potential costs
- Caution clients not to stop therapy abruptly or “rebound” seizures may occur
- Have clients maintain a seizure diary to help determine efficacy

Chemistry/Synonyms

A sulfamate-substituted derivative of D-fructose antiepileptic, topiramate occurs as a white crystalline powder with a bitter taste. Its solubility in water is 9.8 mg/mL; it is freely soluble in alcohol.

Topiramate may also be known as: McN-4853, RWJ-17021, *Epitomax*®, *Topamac*®, *Topamax*®, or *Topimax*®.

Storage/Stability

Topiramate tablets should be stored in tight containers at room temperature (15–30°C; 59–86°F); protect from moisture. Topiramate sprinkle capsules should be stored in tight containers at temperatures below 25°C (76°F); protect from moisture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Topiramate Tablets: 25 mg, 50 mg and 100 mg; Sprinkle Capsules: 15 mg & 25 mg; *Topamax*® (Ortho-McNeil); generic; (Rx)

TORSEMIDE

(*tor-she-myde*) Demadex®, Torasemide

LOOP DIURETIC

Prescriber Highlights

- Potent loop diuretic potentially useful for adjunctive treatment of CHF in dogs & cats; very little information available on clinical use in veterinary medicine
- Approximately 10X more potent, longer diuretic action, & more potassium-sparing (in dogs) than furosemide
- May be more expensive than furosemide, but tablets are now available generically

Uses/Indications

Torsemide is a loop diuretic similar to furosemide, but it is more potent, its diuretic effects persist for a longer period, and it does not cause as much potassium excretion (in dogs). While clinical use in dogs and cats thus far has been minimal, it potentially may be a useful adjunctive treatment for congestive heart failure in dogs and cats, particularly in patients that have become refractory to furosemide.

Pharmacology/Actions

Torsemide, like furosemide inhibits sodium and chloride reabsorption in the ascending loop of Henle via interference with the chloride-binding site of the 1Na⁺, 1K⁺, 2Cl⁻ cotransport system.

Torsemide increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate. In dogs, excretion of potassium is affected much less so than is sodium (20:1); this is approximately twice the ratio of Na:K excreted than with furosemide. In cats, torsemide's effects on potassium excretion appear to be similar to that of furosemide. In dogs, torsemide appears to have differing effects on aldosterone than furosemide. When compared to furosemide, torsemide increases plasma aldosterone levels and inhibits the amount of receptor-bound aldosterone, however, additional research must be performed to determine the clinical significance of these effects.

Pharmacokinetics/Pharmacodynamics

Limited information is available. Oral bioavailability has been reported to be between 80–100% in dogs and cats. Elimination half-life in dogs is about 8 hours which is longer than furosemide. In dogs, diuretic activity begins within one hour of dosing, peaks at about 2 hours and persists for approximately 12 hours.

In cats, peak diuresis occurs about 4 hours post-dose and persists for 12 hours.

Contraindications/Precautions/Warnings

Torsemide should not be used in patients with known hypersensitivity to it or other sulfonylureas, or in anuric patients.

Use torsemide cautiously in patients with significant hepatic dysfunction, hyperuricemia (may increase serum uric acid), or diabetes mellitus (may increase serum glucose).

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance when used in horses.

The injection should be administered IV slowly over a period of 2 minutes. Ototoxicity has occurred in human patients receiving rapid IV administration of other loop diuretics.

Adverse Effects

Adverse effect profiles for dogs and cats have not been established due to the limited use of this drug in veterinary medicine. Furosemide, a related drug, can induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium, magnesium and sodium). Prerenal azotemia may result if moderate to severe dehydration occurs. Hyponatremia is probably the greatest concern, but hypocalcemia, hypokalemia, and hypomagnesemia may all occur. Animals with normal food and water intake are much less likely to develop water and electrolyte imbalances than those that do not.

Other potential adverse effects include gastrointestinal disturbances, hematologic effects (anemia, leukopenia), weakness, and restlessness. Torsemide, unlike furosemide, apparently only rarely causes significant ototoxic effects in humans; very high doses in laboratory animals have induced ototoxicity.

Reproductive/Nursing Safety

No effects on fertility were noted when female and male rats were administered up to 25 mg/kg/day.

No adverse teratogenic effects were seen when pregnant rats and rabbits were administered up to 15X (human dose) and 5X (human dose), respectively. Larger doses did increase fetal resorptions, decreased average body weight, and delayed fetal ossification. In humans, the FDA categorizes torsemide as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if torsemide enters milk, but furosemide is distributed in milk. Clinical significance for nursing offspring is unknown.

Overdosage/Acute Toxicity

In dogs, the oral LD50 is >2 grams/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. Consider gut emptying protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation with fluid, electrolyte and acid-base monitoring; supportive treatment should be initiated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving torsemide and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **enalapril**, **benazepril**): Increased risks for hypotension, particularly in patients who are volume or sodium depleted secondary to diuretics
- **AMINOGLYCOSIDES** (**gentamicin**, **amikacin**, etc.): Other diuretics have been associated with increasing the ototoxic or nephrotoxic risks of aminoglycosides. It is unknown if torsemide can also have these effects and if so, what the clinical significance may be.
- **AMPHOTERICIN B**: Loop diuretics may increase the risk for nephrotoxicity development
- **DIGOXIN**: Can increase the area under the curve of torsemide by 50%, but is unlikely to be of significance clinically; torsemide-induced hypokalemia may increase the potential for digoxin toxicity
- **LITHIUM**: Torsemide may reduce lithium clearance

- **NSAIDs**: Some NSAIDs may reduce the natriuretic effects of torsemide
- **PROBENECID**: Can reduce the diuretic efficacy of torsemide
- **SALICYLATES**: Torsemide can reduce the excretion of salicylates

Laboratory Considerations

- Torsemide can affect **serum electrolytes, glucose, uric acid, and BUN** concentrations.

Doses

■ DOGS/CATS:

While no referenced dosages were located, torsemide could be considered for use as an alternative to furosemide particularly in those patients that have become refractory to furosemide therapy. Torsemide is approximately 10 times more potent than furosemide, so a starting dose of 10% of furosemide could be considered. As torsemide has a more persistent diuretic effect (approximately 12 hours), dosing frequency may also be reduced.

Monitoring

- Serum electrolytes, BUN, creatinine, glucose (if diabetic)
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated

Client Information

- Contact veterinarian if clinical signs of water or electrolyte imbalance occur. Signs such as excessive thirst, lethargy, restlessness, increased urination, GI distress or rapid heart rate may indicate electrolyte or water balance problems.

Chemistry/Synonyms

Torsemide is a pyridyl sulfonylurea loop diuretic that occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol. The injection has a pH >8.3.

Torsemide may also be known as torasemide, AC-3525, AC 4464, BM-02.015, JDL-464, and *Demadex*®. International trade names include *Torem*® and *Unat*®.

Storage/Stability/Compatibility

Torsemide tablets and injectable solution should be stored below 40°C; preferably between 15–30°C (59–86°F). Protect from freezing.

Torsemide injection is stable in NaCl 0.9%, NaCl 0.45%, or D5W. When given IV undiluted, the manufacturer recommends flushing the line to avoid incompatibilities with other drugs secondary to torsemide's high pH.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance.

HUMAN-LABELED PRODUCTS:

Torsemide Tablets: 5 mg, 10 mg, 20 mg, & 100 mg; *Demadex*® (Roche), generic; (Rx)

Torsemide Injection: 10 mg/mL in 2 and 5 mL amps; *Demadex*® (Roche)

TRAMADOL HCL

(*tram-ah-doll*) Ultram®

OPIATE (μ -RECEPTOR) AGONIST

Prescriber Highlights

- ▶ Synthetic μ -receptor opiate agonist that also inhibits reuptake of serotonin & norepinephrine
- ▶ May be useful as an analgesic or antitussive
- ▶ Not a controlled drug in USA, but has some potential for human abuse
- ▶ Appears well tolerated in dogs; sedation most likely adverse effect
- ▶ Avoid use with SSRIs (e.g., fluoxetine) or MAOIs (e.g., selegiline)
- ▶ Relatively inexpensive

Uses/Indications

Tramadol may be a useful alternative or adjunct for the treatment of pain or cough in dogs and, potentially, cats. When used in combination with NSAIDs, it may be particularly useful for chronic pain conditions in dogs. Epidurally administered tramadol may also be useful as an analgesic in horses, but no appropriate commercial dosage forms are presently available in the USA.

Pharmacology/Actions

Tramadol is a centrally acting opiate agonist that has primarily μ -receptor activity, but also inhibits reuptake of serotonin and norepinephrine. These pharmacologic actions all contribute to its analgesic properties. At least one metabolite (O-desmethytramadol; ODT; M1) has activity. When compared to tramadol in lab animal studies, M1 is 6 times more potent an analgesic and has 20 times more potency in binding to μ -receptors. Naloxone only partially antagonizes the analgesic effects of tramadol.

Pharmacokinetics

In dogs after oral administration, bioavailability is about 65%, but there is significant interpatient variability. Volume of distribution is approximately 3.8 L/kg. Total body clearance and half-life are about 55 mL/kg/min and 1.7 hours, respectively. Tramadol is extensively metabolized via several metabolic pathways. At least one metabolite (M1) has agonist activity, but is a minor metabolite in dogs; M1 has a half-life of about 2 hours after oral tramadol administration in dogs.

One study in 8 cats using the immediate release oral tablet, showed high interpatient variability in absorption (with two cats there was not enough data to analyze). The elimination half-life for the parent compound was about 2.5 hours; for the M1 metabolite, 4.5 hours. Neurologic effects (mydriasis, dysphoria) were seen in 25% of cats (2 of 4 females) in the study group and the drug was observed to be unpalatable to cats. (Papich and Bledsoe 2007)

In neonatal and weaned foals, tramadol has different pharmacokinetics. After oral administration, higher bioavailability (53% vs. 20%), shorter time to peak concentration (1 hr. vs. 1.25 hr.), and peak levels occurred with neonatal (2 week old) versus weaned foals (4 months old). Elimination half-life did not significantly differ (approx. 2 hours). The active metabolite (M1; ODT) remained above the reported therapeutic concentration for humans for 3 hours in neonatal foals and 8 hours in weaned foals. (Stewart, Boothe et al. 2006)

Contraindications/Precautions/Warnings

Tramadol is contraindicated in patients hypersensitive to it or other opioids. The combination product containing acetaminophen is contraindicated in cats.

Use with caution in conjunction with other drugs that can cause CNS or respiratory depression. Because tramadol has caused seizures in humans, it should be used with caution in animals with preexisting seizure disorders or receiving other drugs that may reduce the seizure threshold. Like other opiates, tramadol should be used with caution in geriatric or severely debilitated animals. Patients with impaired renal or hepatic function may need dosage adjustments.

While the risk of physical dependence occurring is less than that of several other opiates, it has been reported in humans. The drug should be withdrawn gradually in animals that have received it chronically. While not a controlled substance in the USA, humans can potentially abuse tramadol and significant diversion of the drug reportedly occurs. Veterinarians should be alert to "clients" seeking tramadol for their animals.

Adverse Effects

Tramadol appears to be well tolerated in dogs. Potentially, it could cause a variety of adverse effects associated with its pharmacologic actions, including: CNS effects (excessive sedation, agitation, anxiety, tremor, dizziness), or GI (inappetence, vomiting, constipation to diarrhea).

Very limited information is available on the adverse effects in cats. Dysphoria, mydriasis, and dose avoidance (unpalatability) have been reported.

Approximately 10% of humans receiving the drug develop pruritus. Injectable tramadol may cause respiratory and cardiac depression.

Reproductive/Nursing Safety

In humans, the FDA categorizes tramadol as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) At dosages 3–15 times usual, tramadol was embryotoxic and fetotoxic in laboratory animals. Tramadol and its active metabolite enter maternal milk in very low levels, but the drug's safety in neonates has not been established.

Overdosage/Acute Toxicity

Acute oral overdosage may cause respiratory depression, lethargy, coma, seizure, cardiac arrest and death.

There were 11 exposures to tramadol reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases all 11 were dogs with 1 showing clinical signs (subdued).

Treatment is primarily supportive (maintaining respiration, treating seizures with benzodiazepines or barbiturates, etc.). Naloxone may NOT be useful in tramadol overdoses as it may only partially reverse some of the effects of the drug and may, in fact, increase the risk of seizures. Naloxone did not decrease the drug's lethality in tramadol overdoses given to mice.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tramadol and may be of significance in veterinary patients:

- **DIGOXIN:** In humans, tramadol has been rarely linked to digoxin toxicity
- **MAO INHIBITORS** (including amitraz and possibly, selegiline): Potential for serotonin syndrome; use together should be avoided

- **QUINIDINE:** May increase tramadol concentrations and decrease M1 (active metabolite) concentrations
- **SAME:** Theoretically, concurrent use of SAME with tramadol could cause additive serotonergic effects
- **SSRI ANTIDEPRESSANTS (fluoxetine, sertraline, paroxetine, etc.):** Potential for serotonin syndrome; use together should be avoided; fluoxetine or paroxetine may inhibit tramadol metabolism
- **TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.):** Increased risk for seizures; amitriptyline may inhibit tramadol metabolism
- **WARFARIN:** In humans, increased PT and INR in patients taking tramadol has been reported (relatively rare)

Laboratory Considerations

No specific laboratory interactions or considerations were noted.

Doses

- **DOGS:**
 - a) For analgesia: 1–4 mg/kg PO q8–12h (Hardie, Lascelles et al. 2003)
 - b) For treating chronic cancer pain: 1–4 mg/kg PO q6h (Lascelles 2003)
 - c) As an analgesic: Recent investigations and clinical use suggest a starting dose of 2–5 mg/kg four times daily. (Hellyer 2006)
 - d) 5 mg/kg q6–8h PO (Papich 2006)
- **CATS:**
 - a) For chronic pain: 4 mg/kg PO twice daily (Note: Dose extrapolated from human medicine. Tramadol has not been evaluated for toxicity in cats and has not been used extensively, but early results encouraging) (Lascelles, Robertson et al. 2003)
 - b) **Plumb's Note:** Several clinicians report anecdotally that they use 1/4 of a 50 mg tablet (12.5 mg) orally twice daily in an average sized cat.

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- May be given with or without food
- Keep out of reach of children
- May cause changes in alertness or behavior
- Clients should understand that the clinical experience with this drug in animals is limited and to report adverse effects to the veterinarian

Chemistry/Synonyms

A *mu*-receptor opiate agonist, tramadol HCl occurs as a white crystalline powder that is freely soluble in water or alcohol, and very slightly soluble in acetone. Tramadol is not derived from opium nor is it a semi-synthetic opioid, but is entirely synthetically produced.

Tramadol HCl may also be known as: CG-315; CG-315E; tramadol hydrochloridum; U-26225A; many trade names are available.

Storage/Stability/Compatibility

Unless otherwise labeled, tramadol tablets should be stored at room temperature 25°C (77°F); excursions permitted to 15–30°C (59–86°F). Dispense in tight, light-resistant containers.

Tramadol HCl injection 50 mg/mL (not available commercially in the USA) is reportedly **not compatible** when mixed in the same sy-

ringe with injectable diazepam, diclofenac sodium, indomethacin, midazolam, piroxicam, phenylbutazone, or lysine aspirin.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Tramadol HCl Tablets (film-coated) 50 mg; *Ultram*® (Ortho-McNeil); generic; (Rx)

Tramadol HCl Extended-Release Tablets: 100 mg, 200 mg & 300 mg; *Ultram ER*® (Ortho-McNeil); (Rx). **Note:** Dogs apparently do not absorb this product as well as humans, and potentially could “overdose” if the tablet is chewed.

Tramadol is also available in a fixed dose combination of tramadol HCl 37.5 mg and acetaminophen 325 mg tablets. USA trade name is *Ultracet*® (Ortho-McNeil); (Rx). **Warning:** Be certain this combination product is not dispensed for cats.

In several countries (but not the USA), tramadol injection is available commercially.

TRIAMCINOLONE ACETONIDE

(trye-am-sin-oh-lone) Vetalog®

GLUCOCORTICOID

Prescriber Highlights

- Oral, parenteral, topical & inhaled glucocorticoid that is 4–10X more potent than hydrocortisone; no appreciable mineralocorticoid activity
- Contraindications (relatively): Systemic fungal infections, manufacturer lists: “in viral infections, ...animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, & Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, & active tuberculosis necessitates carefully controlled use.”
- If using for therapy, goal is to use as much as is required & as little as possible for as short an amount of time as possible
- Primary adverse effects are “Cushingoid” in nature with sustained use
- Many potential drug & lab interactions

Uses/Indications

The systemic veterinary labeled product (*Vetalog*® Injection) is labeled as “indicated for the treatment of inflammation and related disorders in dogs, cats, and horses. It is also indicated for use in dogs and cats for the management and treatment of acute arthritis, allergic and dermatologic disorders.”

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of:

endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows.

Cardiovascular System: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs' vasoconstrictive properties and increased blood volume that may be produced.

Cells: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/Autonomic Nervous System: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine System: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T_4) to triiodothyronine (T_3) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Hematopoietic System: Glucocorticoids can increase the numbers of circulating platelets, neutrophils and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells is diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI Tract and Hepatic System: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT) and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulphophthalein) retention time.

Immune System (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

Metabolic Effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts and exophthalmos.

Renal, Fluid, & Electrolytes: Glucocorticoids can increase potassium and calcium excretion; sodium and chloride reabsorption and extracellular fluid volume. Hypokalemia and/or hypocalcemia occur rarely. Diuresis may occur following glucocorticoid administration.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia or hypersensitive to a particular compound. Sustained-release injectable glucocorticoids use is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP) and polyuria (PU), may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially, more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas and mammary development.

Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamcinolone and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Administered concomitantly with glucocorticoids may cause hypokalemia
- **ANALGESICS, OPIATE** and/or **ANESTHETICS, LOCAL (epidural injections)**: Combination with glucocorticoids in epidurals has caused serious CNS injuries and death; do not use more volume than very small intrathecal test doses of these agents with glucocorticoids
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN**: Glucocorticoids may reduce salicylate blood levels

- **BARBITURATES**: May increase the metabolism of glucocorticoids and decrease blood levels
- **CYCLOPHOSPHAMIDE**: Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE**: Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIURETICS, POTASSIUM-DEPLETING** (e.g., **spironolactone**, **triamterene**): Administered concomitantly with glucocorticoids may cause hypokalemia
- **ERYTHROMYCIN, CLARITHROMYCIN**: May increase TMC levels
- **ESTROGENS**: The effects of TMC, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN**: Insulin requirements may increase in patients receiving glucocorticoids
- **ISONIAZID**: TMC may decrease isoniazid levels
- **KETOCONAZOLE** and other **AZOLE ANTIFUNGALS**: May decrease the metabolism of glucocorticoids and increase TMC blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis
- **MITOTANE**: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS**: Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **PHENOBARBITAL**: May increase the metabolism of glucocorticoids and decrease TMC blood levels
- **RIFAMPIN**: May increase the metabolism of glucocorticoids and decrease TMC blood levels
- **VACCINES**: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoid
- **WARFARIN**: TMC may affect INR's; monitor

Laboratory Considerations

- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **serum and urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃ & T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of **I¹³¹** by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

Doses**■ DOGS:**

For glucocorticoid effects:

- 2 mg PO once daily for 7 days; 0.11–0.22 mg/kg IM or SC (Kirk 1989)
- For antiinflammatory effects: 0.05 mg/kg PO two to three times daily (Williamson 2003)
- For tablets: 0.11 mg/kg PO initially once a day, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dose gradually to 0.028–0.055 mg/kg/day. (Booth 1988), (Package insert; *Vetalog® Tablets*—Solvay)
- For injectable product: 0.11–0.22 mg/kg for inflammatory or allergic disorders, and 0.22 mg/kg for dermatological disorders. Effects generally persist for 7–15 days; if symptoms recur, may repeat or institute oral therapy.
For intralesional injection: Usual dose is 1.2–1.8 mg; inject around lesion at 0.5–2.5 cm intervals. Do not exceed 0.6 mg at any one site or 6 mg total dose. May repeat as necessary. (Package insert; *Vetalog® Injection*—Solvay)
- To prevent re-stricture after esophageal dilation: Using an endoscopically directed needle, inject 0.5–1 mL of *Vetalog®* (2 mg/mL) submucosally at time of dilation procedure. Infiltration is done circumferentially at four points around the site. (Marks 2004b)

■ CATS:

For glucocorticoid effects:

- 0.25–0.5 mg PO once daily for 7 days (Kirk 1989)
- For pododermatitis, feline plasmacytic pharyngitis: 2–4 mg (total dose) PO once a day or every other day 0.4–0.6 mg/kg PO once daily, then taper. For pemphigus complex: 0.4–0.8 mg/kg/day PO (Williamson 2003)
- For tablets: 0.11 mg/kg PO initially once a day, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dose gradually to 0.028–0.055 mg/kg/day (Booth 1988), (Package insert; *Vetalog® Tablets*—Solvay)
- For injectable product: 0.11–0.22 mg/kg for inflammatory or allergic disorders, and 0.22 mg/kg for dermatological disorders. Effects generally persist for 7–15 days; if symptoms recur, may repeat or institute oral therapy.
For intralesional injection: Usual dose is 1.2–1.8 mg; inject around lesion at 0.5–2.5 cm intervals. Do not exceed 0.6 mg at any one site or 6 mg total dose. May repeat as necessary. (Package insert; *Vetalog® Injection*—Solvay)
To prevent re-stricture after esophageal dilation: Using an endoscopically directed needle, inject 0.5–1 mL of *Vetalog®* (2 mg/mL) submucosally at time of dilation procedure. Infiltration is done circumferentially at four points around the site. (Marks 2004b)

For feline plasma cell gingivitis-pharyngitis:

- 2–4 mg PO once a day to every other day (DeNovo, Potter, and Woolfson 1988)

For feline polymyopathy:

- 0.5–1 mg/kg PO once a day (Knaack 1988)

■ CATTLE:

For glucocorticoid effects:

- 0.02–0.04 mg/kg IM; 6–18 mg intra-articularly (Howard 1986)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

For glucocorticoid effects:

- 0.1–0.2 mg/kg IM or SC; 3–6 mg subconjunctivally (Robinson 1987)
- 0.011–0.022 mg/kg PO twice daily;
0.011–0.022 mg/kg IM or SC;
6–18 mg intra-articularly or intrasynovially, may repeat after 3–4 days (Package inserts; *Vetalog® Powder and Injection*—Solvay)
- For intra-articular injection: 12 mg IA on days 0, 13, 27 (McClure 2002)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Chemistry/Synonyms

Triamcinolone acetonide, a synthetic glucocorticoid, occurs as slightly odorous, white to cream-colored, crystalline powder with a melting point between 290–294°C. It is practically insoluble in water, very soluble in dehydrated alcohol and slightly soluble in alcohol. The commercially available sterile suspensions have a pH range of 5–7.5.

Triamcinolone acetonide may also be known as: triamcinoloni acetonidum; many trade names are available.

Storage/Stability

Triamcinolone acetonide products should be stored at room temperature (15–30°C); the injection should be protected from light.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Triamcinolone Acetonide Tablets: 0.5 mg, 1.5 mg; *Cortalone Tablets®* (Vedco), generic (Boehringer Ingelheim), *Triacet® Tablets* (Phoenix), *Triamtabs®* (Butler); (Rx). Approved for use in dogs and cats.

Triamcinolone acetonide Suspension for Injection: 2 mg/mL; 6 mg/mL; *Vetalog® Parenteral* (Fort Dodge); (Rx). Approved for use in dogs, cats, and horses not intended for food.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Triamcinolone Acetonide Injection: 10 mg/mL suspension & 40 mg/mL suspension in 1 mL, 5 mL and 10 mL vials; *Kenalog-10 & -40* (Bristol-Myers Squibb); (Rx)

Triamcinolone Hexacetonide Injection: 5 mg/mL & 20 mg/mL suspension in 1 mL & 5 mL vials; *Aristospan Intralesional®* (Fujisawa); (Rx)

Many topical preparations are available, alone and in combination with other agents. Oral mucosal paste & Inhaled products are also approved. All are Rx.

TRIAMTERENE

(trye-am-the-reen) Dyrenium®

POTASSIUM-SPARING DIURETIC

Prescriber Highlights

- ▶ Potassium-sparing diuretic that may be considered as an alternative to spironolactone for treating CHF in dogs; limited clinical experience with this drug in dogs/cats
- ▶ Contraindications: Anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation
- ▶ Hyperkalemia possible; must monitor serum K+

Uses/Indications

Triamterene is a potassium-sparing diuretic that potentially could be used as an alternative to spironolactone for the adjunctive treatment of congestive heart failure in dogs, however, there is little experience associated with its use in dogs or cats.

Pharmacology/Actions

By exerting a direct effect on the distal renal tubule, triamterene inhibits the reabsorption of sodium in exchange for hydrogen and potassium ions. Unlike spironolactone, it does not competitively inhibit aldosterone. Triamterene increases excretion of sodium, calcium, magnesium and bicarbonate; urinary pH may be slightly increased. Serum concentrations of potassium and chloride may be increased. When used alone, triamterene has little effect on blood pressure. Triamterene can reduce GFR slightly, probably by affecting renal blood flow. This effect is reversible when the medication is discontinued.

Pharmacokinetics

Pharmacokinetic data for dogs or cats was not located. In humans, triamterene is rapidly absorbed after oral administration and oral bioavailability is about 85%. Onset of diuresis occurs in 2–4 hours and diminishes after about 8 hours. Triamterene is metabolized in the liver to 6-p-hydroxytriamterene and its sulfate conjugate. These metabolites are eliminated in the bile/feces and urine; elimination half-life is about 2 hours.

Contraindications/Precautions/Warnings

Triamterene is contraindicated for human patients (and presumably dogs and cats) with anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, history of triamterene-induced hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation.

Adverse Effects

Because triamterene has been infrequently used in veterinary medicine, an accurate adverse effect profile for small animals is not known, however, hyperkalemia is a definite possibility and monitoring of electrolytes and renal function are necessary. In humans, hyperkalemia rarely occurs in patients with normal urine output and potassium intake.

Less common adverse effects reported in humans include headache/dizziness, GI effects, hyponatremia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking triamterene. Other rare adverse effects include triamterene-nephrolithiasis, agranulocytosis, thrombocytopenia, or megaloblastosis.

Reproductive/Nursing Safety

Studies to determine triamterene's effects on fertility have not been performed.

Studies in pregnant rats given triamterene at 6–20X (human dose) did not show adverse effects to the fetuses. Triamterene crosses the placental barrier. For humans, triamterene is either in FDA category **B** or category **C**, depending on the reference. Category **C** for use during pregnancy states: *Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.* If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Triamterene is distributed into milk. Although unlikely to pose much risk to nursing animals, safety during nursing cannot be assured.

Overdosage/Acute Toxicity

The oral LD50 for triamterene in mice is 380 mg/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. GI effects or hypotension are also possible. Consider gut emptying protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation, with fluid, electrolyte (especially serum potassium) and acid-base monitoring. Supportive treatment should be initiated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamterene and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., enalapril, benazepril): Increased risks for hyperkalemia
- **ANTIIDIABETIC AGENTS** (insulin, oral hypoglycemic agents): Triamterene may increase blood glucose
- **Antihypertensive agents**: Possible potentiation of hypotensive effects
- **DIURETICS, POTASSIUM-SPARING** (spironolactone, amiloride): Increase risk of hyperkalemia; use of these drugs with triamterene in humans is contraindicated
- **LITHIUM**: Triamterene may reduce lithium clearance
- **NSAIDs**: Triamterene with NSAIDs (esp. indomethacin) may increase the risks of nephrotoxicity
- **POTASSIUM SUPPLEMENTS** or **HIGH POTASSIUM FOODS**: Increased risk for hyperkalemia

Laboratory Considerations

- **Quinidine**: Triamterene may interfere with fluorescent assay of quinidine

Doses

- **DOGS**:
 - a) For adjunctive treatment of recurrent heart failure associated with chronic mitral valve insufficiency: 1–2 mg/kg PO q12h. Documentation of use is limited; spironolactone is drug of choice. (Haggstrom, Kvart et al. 2005)
 - b) As a diuretic for adjunctive treatment of CHF: 2–(4) mg/kg/day PO (Ware 2003)

Monitoring

- Serum electrolytes (especially potassium), BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Signs of edema; patient weight, if indicated

Client Information

- Give this medication with food to help prevent stomach upset
- Urine may develop a bluish hue, this is normal
- Because this medication has not been used very much in dogs or cats; report any unusual effects to the veterinarian

Chemistry/Synonyms

Triamterene is structurally related to folic acid and occurs as a yellow, odorless, crystalline powder. It is practically insoluble in water and very slightly soluble in alcohol. At 50°C, it is slightly soluble in water. In acidified solutions, triamterene gives off a blue fluorescence.

Triamterene may also be known as NSC-77625, KF-8542, FI-6143, triamteren, trimaterenum or triamtereen, *Dyrenium*®, . International trade names include *Dytac*®, *Dyazide*®, *Maxzide-25*® and *Triteren*®. There are many international trade names for combination products with hydrochlorothiazide.

Storage/Stability

Triamterene capsules should be stored between 15–30°C (59–86°F) in tight, light-resistant containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

HUMAN-LABELED PRODUCTS:

Triamterene Capsules: 50 mg, 100 mg; *Dyrenium*® (Wellspring); (Rx)

In humans, triamterene is often prescribed as a fixed-dose combination with hydrochlorothiazide. Products include:

Triamterene 37.5 mg/Hydrochlorothiazide 25 mg Tablets and Capsules; generic, *Dyazide*®, *Maxzide-25*®; (Rx)

Triamterene 50 mg/Hydrochlorothiazide 25 mg Capsules; generic; (Rx)

Triamterene 75 mg/Hydrochlorothiazide 50 mg Tablets; generic, *Maxzide*®; (Rx)

TRIENTINE HCL

(trye-en-teen) Syprine®

CHELATING AGENT

Prescriber Highlights

- ▶ Oral copper chelating agent for copper hepatopathy
- ▶ Probably fewer adverse effects than penicillamine, but acute renal failure possible
- ▶ Very limited experience with this drug
- ▶ More expensive than penicillamine; may need to be compounded into smaller dosages
- ▶ Give on an empty stomach

Uses/Indications

Trientine may be useful for the treatment of copper-associated hepatopathy in dogs, particularly when dogs cannot tolerate the adverse effects (e.g., vomiting) associated with penicillamine.

Pharmacology/Actions

Trientine is an effective chelator of copper and increases its elimination via urinary excretion. It apparently has a greater affinity for copper in plasma than penicillamine, but penicillamine has a greater affinity for tissue copper.

Pharmacokinetics

No data was located.

Contraindications/Precautions/Warnings

Trientine is contraindicated in patients hypersensitive to it. It is not indicated for cystinuria, rheumatoid arthritis, or biliary cirrhosis.

Adverse Effects

Albeit with limited veterinary experience, trientine has had relatively minimal adverse effects in dogs treated for copper hepatotoxicity, but acute renal failure has been reported. Human patients have developed iron deficiency anemia after taking trientine long-term. There is a chance for topical dermatitis developing if trientine gets on skin; wash off immediately. The drug should be given in a capsule (may need to be compounded) and not sprinkled on food.

Reproductive/Nursing Safety

Trientine is a potential teratogen. It was teratogenic in rats given doses similar to those for humans and should only be used in pregnancy when the benefits to the mother outweigh the risks to offspring. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in breast milk. Exercise caution when administering to nursing patients.

Overdosage/Acute Toxicity

Little information is available; a case of a human ingesting 30 g of trientine without significant morbidity has been reported.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trientine and may be of significance in veterinary patients:

- **IRON:** Iron and trientine inhibit the absorption of one another; if iron therapy is needed, give doses at least 2 hours apart from one another
- **ZINC:** Because trientine may also chelate zinc or other minerals, separate doses as above

Doses**■ DOGS:**

As a chelator for copper hepatotoxicity:

- 10–15 mg/kg PO twice daily; 1–2 hours before a meal (Twedt 1999)
- 10–15 mg/kg PO q12h; give one hour before meals (Johnson 2000)
- 15–30 mg/kg PO twice daily (q12h). Give prior to meals (Richter 2002)

Monitoring

- Periodic quantitative hepatic copper levels

Client Information

- While it is preferable to give on an empty stomach, if the drug causes vomiting or lack of appetite give with a small amount of food

Chemistry/Synonyms

An oral copper chelator, trientine HCl occurs as a white to pale yellow crystalline powder. It is hygroscopic and freely soluble in water.

Trientine HCl may also be known as: MK-0681, 2,2,2-tetramine, trien hydrochloride, triethylenetetramine dihydrochloride, trientine hydrochloride or *Syprine*®.

Storage/Stability

Store trientine capsules in the refrigerator (2–8°C) in tightly closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Trientine HCl Capsules: 250 mg; *Syprine*® (Merck); (Rx)

TRILOSTANE

(trye-loe-stane) Veteryl®

ADRENAL STEROID SYNTHESIS INHIBITOR

Prescriber Highlights

- ▶ Competitive inhibitor of 3-beta hydroxysteroid dehydrogenase thereby reducing synthesis of cortisol, aldosterone, & adrenal androgens
- ▶ May be useful in dogs for treatment of pituitary-dependent hyperadrenocorticism, adrenal dependent hyperadrenocorticism, Alopecia X in Pomeranians & Alaskan malamutes; in cats for treatment of feline pituitary dependent hyperadrenocorticism, & in horses for equine hyperadrenocorticism (HAC)
- ▶ In USA, must presently be imported
- ▶ Potential adverse effects in dogs include lethargy, inappetence, vomiting, electrolyte abnormalities, & diarrhea
- ▶ Rare case reports of hypoadrenocorticism & death
- ▶ Expense of treatment may be an issue

Uses/Indications

Trilostane may be useful for treating pituitary-dependent hyperadrenocorticism or adrenal dependent hyperadrenocorticism in dogs, feline pituitary-dependent hyperadrenocorticism, and equine hyperadrenocorticism (HAC). It may also be useful in treating Pomeranians with Alopecia X and Alaskan malamutes with adult-onset alopecia.

Pharmacology/Actions

Trilostane is a competitive inhibitor of 3-beta hydroxysteroid dehydrogenase thereby reducing synthesis of cortisol, aldosterone, and adrenal androgens. Inhibition is reversible and apparently dose dependent.

Pharmacokinetics

In dogs, orally administered trilostane is rapidly, but erratically absorbed with peak levels occurring between 1.5–2 hours post dose. It is unknown whether the presence of food in the gut significantly alters absorption characteristics. After 18 hours, the drug reportedly returns to baseline levels. Effects on cortisol production apparently last for no more than 20 hours, and more likely wane within 10 hours of dosing. Trilostane is metabolized in the liver to several metabolites including ketotrilostane, which is active.

Contraindications/Precautions/Warnings

Trilostane is contraindicated in animals hypersensitive to it. It should be used with caution in patients with renal or hepatic impairment.

Adverse Effects

Trilostane appears to be relatively well tolerated in dogs. Lethargy, mild electrolyte abnormalities and inappetence are commonly noted during the first few days of therapy secondary to steroid withdrawal. Vomiting and diarrhea may also be seen. Withholding the drug for a few days and then giving it every other day for a week may alleviate lethargy and vomiting. Rarely, acute death or development of hypoadrenocorticism (including adrenal necrosis) occurring in dogs after receiving trilostane have been anecdotally reported.

In one study of trilostane given to 20 horses with equine Cushing's (McGowan and Neiger 2003), no adverse effects were noted.

Reproductive/Nursing Safety

Because trilostane can significantly reduce the synthesis of progesterone *in vivo*, it should not be used in pregnancy. Trilostane reportedly (not confirmed) is classified by the FDA as a category X drug (*Contraindicated in pregnancy*).

Information on trilostane levels in maternal milk were not located; use with caution in lactating animals.

Overdosage/Acute Toxicity

Specific information on trilostane acute toxicity was not located. One source states that trilostane overdoses would be unlikely to threaten life and no clinical signs would be expected. However, blood pressure, hydration status, and electrolyte balance should be monitored. If the animal is stressed, consider giving exogenous corticosteroids short-term. Because the drug's effects are relatively short lived, monitoring of patients without complications should only be required for a few days post ingestion.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trilostane and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **benazepril**, **enalapril**): Could increase risk for hyperkalemia
- **AMINOGLUTETHIMIDE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **KETOCONAZOLE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **MITOTANE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **POTASSIUM-SPARING DIURETICS** (e.g., **spironolactone**): Could increase risk for hyperkalemia
- **POTASSIUM-SUPPLEMENTS; HIGH POTASSIUM FOODS**: Could increase risk for hyperkalemia

Laboratory Considerations

- No specific laboratory interactions or considerations were located.

Doses

■ DOGS:

For treatment of canine hyperadrenocorticism (HAC):

- For treatment of canine hyperadrenocorticism (HAC) whether due to adrenal tumor or PDH: Initial therapy at 2–10 mg/kg PO once daily. Adjust dosage per monitoring parameters below. Doses of up to 50 mg/kg/day divided twice daily have been given without untoward side effects. Give with food. Some dogs require twice daily administration.

ACTH stimulation test done at 10–14 days, 30 days and 90 days after starting therapy. ACTH stimulation tests should be performed 4–6 hours post-trilostane dose. Interpret ACTH test in light of physical exam. If ACTH Stim results are <20 nmol/L (0.72 mcg/dl), then the drug is discontinued for 48–72 hours and then re-started at a lower dosage. If ACTH Stim results are >200 nmol/L (7.2 mcg/dl), then the dose is increased. If the ACTH Stim results are between these two values and the dog is clinically well-controlled, then no change. If between these two results and the patient appears not to be clinically well-controlled, then the drug may need to be given twice daily. Once the dog is stable, repeat ACTH Stim test every 3–6 months. (Neiger 2004)

- Author's (Feldman) experience is that trilostane is not more effective or safer than mitotane and that trilostane is less predictable (under dose, over dose, resolution of signs, or the need for dosing more than once per day) than mitotane.

If using trilostane current recommendation is: Initiate at 1 mg/kg PO once daily and continue for about one week until a veterinary recheck can occur. Have owners collect a small urine sample from their dog before leaving home the morning of the scheduled recheck prior to trilostane administration. Trilostane should then be given and the dog should be seen by veterinarian 2 to 3 hours later. The goal of therapy is an owner who is completely pleased with the response. The urine should be checked, at a minimum, for specific gravity, glucose and urine cortisol:creatinine ratio (UCCR). An ACTH stimulation test should be started at the time that the dog is seen (about 2 to 3 hours after trilostane dose). The UCCR result should be within the reference interval and the post-ACTH serum cortisol concentration should be between 1.5 and 5.5 mcg/dL. If the serum cortisol concentration is within that goal and the UCCR is abnormal, the medication should be given twice daily. If the serum cortisol concentration is too high, the trilostane dose should be increased and if the serum cortisol concentration is too low, the dose should be decreased. This approach should be utilized at each recheck until the dog is doing well. (Feldman 2007)

For treatment of Alopecia X:

- In Alaskan Malamutes: 3–3.6 mg/kg PO twice a day for 4–6 months. Three dogs treated; no adverse effects reported. (Leone, Vercelli et al. 2005)
- In Miniature poodles and Pomeranians: Average dose was 10.85 mg/kg per day given either once a day or divided twice a day for 4–8 weeks. (Cerundolo, Lloyd et al. 2004)

■ CATS:

- For treatment of feline hyperadrenocorticism: 7 mg/kg/day divided and given twice daily. Doses of up to 60 mg per cat per day have been used in a small number of cats with PDH. (Greco 2007a)

■ HORSES:

- For treatment of equine Cushing's syndrome: 0.4–1 mg/kg (total dose 120–240 mg) PO once daily. (McGowan and Neiger 2003)

Monitoring

- Clinical effects
- Adverse effects
- Serum electrolytes
- Urinalysis including specific gravity, glucose and urine cortisol:creatinine ratio (UCCR)
- ACTH stimulation tests (see doses for recommendations)

Client Information

- Keep out of reach of children and pets
- Wear gloves or wash hands thoroughly after handling
- Clients should report any adverse effects to the veterinarian
- Give the drug with food, unless otherwise directed by veterinarian
- Clients should understand that trilostane is a treatment for the condition and not a cure

Chemistry/Synonyms

A synthetic steroid analog, trilostane has a molecular weight of 329.4 and its chemical name is 4-alpha, 5-alpha-Epoxy-17-beta-hydroxy-3-oxoandrostane-2-alpha-carbonitrile. It reportedly is relatively insoluble in water.

Trilostane may also be known as: WIN 24540, *Vetoryl*®, *Desopan*®, *Modrastane*® or *Modrenal*®.

Storage/Stability/Compatibility

Commercially available trilostane capsules should be stored at room temperature in tight, light-resistant containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA.

In the UK, Trilostane Oral Capsules 60 mg, 120 mg are available. Trade name is *Vetoryl*® (Arnolds Veterinary Products, Cartmel Drive, Harlescott, Shrewsbury, Shropshire SY1 3TB, U.K.; FAX Number: +44 0174346211). *Vetoryl*® can be legally imported into the USA by obtaining prior approval from the FDA. See the appendix for step-wise instructions.

One source that has been recommended for obtaining trilostane after obtaining FDA approval is: www.mastersmarketing.com (Mealey 2007)

HUMAN-LABELED PRODUCTS:

Modrastane® is reportedly still an approved human drug, but was withdrawn from the market in the USA in 1994.

TRIMEPRAZINE TARTRATE WITH PREDNISOLONE

(trye-mep-ra-zeen) Temaril-P®

PHENOTHIAZINE ANTIHISTAMINE
& CORTICOSTEROID

Prescriber Highlights

- ▶ Combination phenothiazine antihistamine & corticosteroid used for pruritus & potentially as an antitussive
- ▶ Relatively Contraindicated: Systemic fungal infections, hypovolemia, or shock & in patients with tetanus or strychnine intoxication. Caution: Hepatic dysfunction, cardiac disease, active bacterial or viral infections, peptic ulcer, acute psychoses, corneal ulcer, Cushingoid syndrome, diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, general debilitation, very young animals
- ▶ Goal is to use as much as is required & as little as possible for as short an amount of time as possible
- ▶ Primary adverse effects: Sedation, may cause significant hypotension, cardiac rate abnormalities, hypo- or hyperthermia, "Cushingoid" effects with sustained use
- ▶ Many potential drug & lab interactions

Uses/Indications

Trimeprazine with prednisolone is used for the treatment of pruritic conditions, especially if induced by allergic conditions. Many dermatologists believe that when prednisolone is combined with trimeprazine (*Temaril-P*®), less prednisolone is required to control pruritus. The manufacturer suggests the drug is for use in dogs either for pruritic conditions or as an antitussive.

Pharmacology/Actions

Trimeprazine has antihistaminic, sedative, antitussive, and antipruritic qualities. The veterinary-approved product also has prednisolone in its formulation that provides additional antiinflammatory effects.

Pharmacokinetics

The pharmacokinetics of trimeprazine have apparently not been studied.

Contraindications/Precautions/Warnings

The contraindications and precautions of this product follow those of the other phenothiazines and antihistaminic agents. For more information, it is suggested to review the acepromazine and chlorpheniramine monographs.

Adverse Effects

For trimeprazine, possible adverse reactions include: sedation, depression, hypotension and extrapyramidal reactions (rigidity, tremors, weakness, restlessness, etc.).

Additional adverse effects, if using the product containing steroids include: elevated liver enzymes, weight loss, polyuria/polydipsia, vomiting, and diarrhea. If used chronically, therapy must be withdrawn gradually and Cushing's syndrome may develop.

The manufacturer of the veterinary combination product (*Temaril*®-P) includes the following adverse effects in its package insert: sodium retention and potassium loss, negative nitrogen balance, suppressed adrenocortical function, delayed wound healing,

osteoporosis, possible increased susceptibility to and/or exacerbation of bacterial infections, sedation, protruding nictitating membrane, blood dyscrasias. In addition, intensification and prolongation of the action of sedatives, analgesics or anesthetics can be noted and potentiation of organophosphate toxicity and of procaine HCl activity.

Reproductive/Nursing Safety

The manufacturer of the veterinary combination product (*Temaril*®-P) warns that corticosteroids can induce the first stages of parturition if administered during the last trimester of pregnancy.

Overdosage/Acute Toxicity

Acute overdosage should be handled as per the acepromazine monograph found at the beginning of the book.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine (a related phenothiazine antihistamine) or prednisolone and may be of significance in veterinary patients:

- **ACE INHIBITORS:** Phenothiazines may increase effects
- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTIARRHEAL MIXTURES** (e.g., **Kaolin/pectin, bismuth subsalicylate mixtures**): May cause reduced GI absorption of oral phenothiazines
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine, neostigmine, etc.**): In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels
- **CISAPRIDE:** Increased risk for cardiac arrhythmias when used with phenothiazines
- **CNS DEPRESSANT AGENTS** (**barbiturates, narcotics, anesthetics, etc.**): May cause additive CNS depression if used with phenothiazines
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
- **DIGOXIN:** Secondary to hypokalemia, increased risk for arrhythmias
- **DIURETICS, POTASSIUM-DEPLETING** (**furosemide, thiazides**): When administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May increase metabolism
- **ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE:** May decrease metabolism

- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of other ulcerogenic drugs with glucocorticoids may increase risk
- **PAROXETINE:** May increase phenothiazine plasma levels
- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids
- **PHENYTOIN:** May increase the metabolism of glucocorticoids
- **RIFAMPIN:** May increase the metabolism of glucocorticoids
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease serum **potassium**.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃** & **T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I¹³¹ by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids or trimeprazine.
- False-negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

Doses

■ DOGS:

- For antipruritic and antitussive therapy: Weight up to 10 lb = 1/2 tab PO twice daily; 11–20 lb = 1 tablet twice daily; 21–40 lb = 2 tablets twice daily; over 40 lb = 3 tablets twice daily. After 4 days reduce dose to 1/2 of initial dose or to an amount just sufficient to maintain remission of symptoms; adjust as necessary. (Package Insert; *Temaril®-P*—Pfizer)
- For treatment of pruritus: 1 tablet per 10 kg of body weight once daily for 3–5 days, then every other day. Giving with an EFA (essential fatty acid) may reduce the dose and frequency, if not the need for, glucocorticoids. (White 2003a)
- For atopic dermatitis: 1 tablet of *Temaril®-P* per 5 kg body weight q12h for one week, then once daily for one week, then q48h (every other day). (Hillier 2006e)

Monitoring

- Efficacy
- Degree of sedation, and anticholinergic effects
- Adverse effects associated with corticosteroids

Client Information

- Follow veterinarians dosage recommendations carefully
- Dog's appetite and water consumption may increase
- If side effects are worrisome, contact veterinarian

Chemistry/Synonyms

A phenothiazine antihistamine related to promethazine, trimeprazine tartrate occurs as an odorless, white, to off-white crystalline powder with a melting range of 160–164°C. Approximately 0.5 gm is soluble in 1 mL water, and 0.05 gm is soluble in 1 mL of alcohol.

Trimeprazine Tartrate may also be known as: trimeprazine tartrate, alimemazine tartrate, *Chemists Own Peetalix®*, *Nedeltran®*,

Panectyl®, *Repelitin®*, *Temaril®*, *Theralen®*, *Theralene®*, *Theralene®*, *Vallergan®*, or *Variargil®*.

Storage/Stability

Store trimeprazine products at room temperature (15–30°C); protect tablets from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No single agent trimeprazine products are approved for veterinary medicine.

Trimeprazine Tartrate 5 mg; Prednisolone 2 mg Tablets; *Temaril-P® Tablets* (Pfizer); (Rx). Approved for use in dogs. Trade name in Canada is *Vanectyl-P®*.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

Trimethoprim/Sulfa—See Sulfadiazine/Trimethoprim

TRIPLENNAMINE HCL

(tri-pel-ehn-a-meen) Re-Covr®

ANTI-HISTAMINE

Prescriber Highlights

- Oral & injectable antihistamine
- Contraindications: Do not give IV to horses
- Adverse Effects: CNS stimulation (if given IV to horses), sedation, depression, ataxia, GI effects (oral use)

Uses/Indications

Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects. TripeleNNamine has been used as a CNS stimulant in “Downer cows” when administered slow IV.

Pharmacology/Actions

Antihistamines (H₁-receptor antagonists) competitively inhibit histamine at H₁ receptor sites. They do not inactivate or prevent the release of histamine, but can prevent histamine's action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). TripeleNNamine is considered to have moderate sedative activity and minimal anticholinergic activity when compared to other antihistamines.

Pharmacokinetics

The pharmacokinetics of tripeleNNamine have apparently not been thoroughly studied in domestic animals or humans.

Contraindications/Precautions/Warnings

Do not administer TripeleNNamine IV in horses (see Adverse Effects).

Adverse Effects

CNS stimulation (hyperexcitability, nervousness, and muscle tremors) lasting up to 20 minutes, has been noted in horses after receiving tripeleNNamine intravenously. Other effects seen (in all species) include CNS depression, incoordination, and GI disturbances.

Overdosage/Acute Toxicity

Overdosage of tripeleennamine reportedly can cause CNS excitation, seizures and ataxia. Treat symptomatically and supportively if clinical signs are severe. Phenytoin (IV) is recommended in the treatment of seizures caused by antihistamine overdose in humans; barbiturates and diazepam are generally avoided.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tripeleennamine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER:** Increased sedation can occur if chlorpheniramine is combined with other CNS depressant drugs
- **HEPARIN, WARFARIN:** Antihistamines may partially counteract the anti-coagulation effects of heparin or warfarin.

Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to **antigen skin testing**. In humans, it is suggested that antihistamines be discontinued at least 4 days prior to testing.

Doses

It is recommended to warm the solution to near body temperature before injecting; give IM injections into large muscle areas.

- **DOGS:**
 - a) 1 mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)
- **CATS:**
 - a) 1 mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)
- **CATTLE:**
 - a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IV (for more immediate effect) or IM q6–12h as needed (Package Insert; *Re-Covr*®—Solvay)
 - b) As adjunctive treatment in “Downer Cow Syndrome” as a CNS stimulant: 0.5 mg/kg slow IV in conjunction with parenteral mineral treatment (Caple 1986)
 - c) 1 mg/kg IV or IM (Howard 1986)
- **HORSES: (Note: ARCI UCGFS Class 3 Drug)**
 - a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IM q6–12h as needed (Package Insert; *Re-Covr*®—Solvay)
 - b) 1 mg/kg IM (Robinson 1987)
- **SWINE:**
 - a) 1 mg/kg IV or IM (Howard 1986)

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

An ethylenediamine-derivative antihistamine, tripeleennamine HCl occurs as a white, crystalline powder that will slowly darken upon exposure to light. It has a melting range of 188–192°C and pK_as of 3.9 and 9.0. One gram is soluble in 1 mL of water or 6 mL of alcohol.

Tripeleennamine HCl may also be known as: tripeleennaminium chloride, *Azaron*®, *Etono*®, *Fenistil*®, *PBZ*®, *Pelamine*®, *Pyribenzamine*®, *Re-Covr*® or *Vaginex*®.

Storage/Stability

Store the injection at room temperature and protect from light; avoid freezing or excessive heat. Tablets should also be stored at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tripeleennamine HCl for Injection: 20 mg/mL in 20 mL, 100 mL, and 250 mL vials; *Re-Covr*® (Fort Dodge), generic (various manufacturers and trade names); (Rx). Tripeleennamine HCl injection is approved for use in cattle and horses. Treated cattle must not be slaughtered for food purposes for 4 days following the last treatment. Milk must not be used for food for 24 hours (2 milkings) after treatment. No specific tolerance for residues has been published.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

TSH—See Thyrotropin

TULATHROMYCIN

(too-la-throe-mye-sin) Draxxin®

INJECTABLE MACROLIDE ANTIBIOTIC

Prescriber Highlights

- Injectable macrolide antibiotic for cattle & swine
- Very long tissue half-lives; one dose treatment
- Not for lactating dairy cattle or veal calves
- Local injection site reactions most likely adverse effect

Monograph by Elaine Lust, PharmD

Uses/Indications

In beef and non-lactating dairy cattle, tulathromycin is indicated for the treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica*, *Pasteurella multocida*, *Histophilus somni* (*Haemophilus somnus*) and *Mycoplasma bovis*; and for the control of respiratory disease in cattle at high risk of developing BRD, associated with *Mannheimia haemolytica*, *Pasteurella multocida* and *Histophilus somni* (*Haemophilus somnus*).

In swine, tulathromycin is indicated for the treatment of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae*, *Pasteurella multocida*, *Bordetella bronchiseptica*, and *Haemophilus parasuis*.

Pharmacology/Actions

While tulathromycin is a macrolide antibiotic such as erythromycin or azithromycin, it is structurally unique in that it has three amine groups (tribasic), while erythromycin and azithromycin have one (monobasic) and two (dibasic) groups, respectively. The tribasic group of compounds are called triamilide macrolides.

It is believed that tulathromycin's tribasic structure allows it to better penetrate gram-negative pathogenic bacteria and its low affinity for bacterial efflux pumps may allow the drug to remain and accumulate within the bacteria.

The mechanism of action of tulathromycin is similar to other macrolides in that it inhibits protein synthesis by penetrating the cell wall and binding to the 50S ribosomal subunits in susceptible bacteria. It is considered a bacteriostatic antibiotic, but it possesses some bactericidal activity as well, particularly for *Mannheimia haemolytica* and *Pasteurella multocida*.

Tulathromycin's efficacy is probably enhanced by its ability to accumulate and be released by host phagocytic cells. Neither time-dependent nor concentration-dependent models may accurately predict or describe the drug's efficacy. Some modern macrolides (e.g., azithromycin) efficacy may be more predictive by assessing the total drug exposure to the pathogen; the AUC:MIC ratio may be helpful.

Pharmacokinetics

In feeder calves given 2.5 mg/kg SC (in the neck), tulathromycin is rapidly and nearly completely absorbed (bioavailability >90%). Peak plasma concentrations generally occur within 15 minutes after dosing. Volume of distribution is very large (approximately 11 L/kg) and total systemic clearance is approximately 170 mL/hr/kg. This extensive volume of distribution is largely responsible for the long elimination half-life of this compound. In plasma, elimination half life is approximately 2.75 days, but in lung tissue it is about 8.75 days. Tulathromycin is eliminated from the body primarily unchanged via biliary excretion.

Following intramuscular administration to feeder pigs at a dosage of 2.5 mg/kg, tulathromycin is readily and rapidly absorbed (bioavailability 88%) with peak levels occurring in about 15 minutes. Tulathromycin rapidly distributes into body tissues, and the volume of distribution is 13–15 L/kg. Plasma half-life is approximately 60–90 hours, but lung tissue half life is about 5.9 days. Tulathromycin is eliminated from the body primarily unchanged via the feces and urine.

Contraindications/Precautions/Warnings

Tulathromycin is contraindicated in animals with a prior hypersensitivity reaction to the drug.

Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in pre-ruminating calves. Do not use in calves to be processed for veal.

Swine intended for human consumption must not be slaughtered within 5 days from the last treatment.

Adverse Effects

At labeled doses, adverse effects appear to be minimal in cattle and swine. Transient hypersalivation has been reported and one feeder calf in field studies developed transient dyspnea. Injection site reactions are most commonly reported and there have been some reports to the FDA's Adverse Drug Reporting database of anorexia in cattle.

Hypersensitivity reactions are possible, but no reports were located.

Subcutaneous or intramuscular injection can cause a transient local tissue reaction that may result in trim loss at slaughter.

Reproductive/Nursing Safety

Reproductive safety is not known, the product is labeled: "The effects of *Draxxin*® on bovine (and porcine) reproductive performance, pregnancy and lactation have not been determined.

Overdosage/Acute Toxicity

In cattle (feeder calves), single subcutaneous doses of up to 25 mg/kg caused transient indications of pain at the injection, including head shaking and pawing at the ground. Injection site swelling, discoloration of the subcutaneous tissues at the injection site and corresponding histopathologic changes were seen in animals in all dosage groups.

In swine, single IM doses of up to 25 mg/kg caused transient indications of pain at the injection site, restlessness, and excessive vocalization. Tremors occurred briefly in one animal receiving 7.5 mg/kg BW.

No systemic treatment for single overdoses should be necessary, localized treatment at the injection site (e.g., ice pack) to reduce swelling and pain as well as approved analgesic medications can be considered.

Drug Interactions

No drug interactions are noted in the manufacturer's label and none could be found in other references for tulathromycin.

Laboratory Considerations

No concerns were noted

Doses

■ CATTLE:

For labeled indications:

- a) Inject subcutaneously as a single dose in the neck at a dosage of 2.5 mg/kg (1.1 mL/100 lb) body weight (BW). Do not inject more than 10 mL per injection site. (Label directions; *Draxxin*®—Pfizer)

■ SWINE:

For labeled indications:

- a) Inject intramuscularly as a single dose in the neck at a dosage of 2.5 mg/kg (0.25 mL/22 lb) BW. Do not inject more than 2.5 mL per injection site. (Label directions; *Draxxin*®—Pfizer)

Monitoring

- Clinical efficacy

Client Information

- Follow dosing guidelines exactly; adhere to withdrawal times
- Not for female dairy cattle (20 months or older) or veal calves
- Cattle are dosed subcutaneously in the neck, not more than 10 mL per injection site
- Swine are dosed intramuscularly in the neck, not more than 2.5 mL per injection site

Chemistry/Synonyms

Tulathromycin is a semi-synthetic macrolide antibiotic of the subclass triamilide. It occurs as white to off-white-crystalline powder that is readily soluble in water at pH<8. At a pH of 7.4 (physiological pH), tulathromycin (a weak base) is approximately 50 times more soluble in hydrophilic than hydrophobic media.

The commercially available injection contains 100 mg/mL of tulathromycin in an equilibrated mixture of the two isomeric forms of tulathromycin in a 9:1 ratio. The injectable vehicle consists of 50% propylene glycol, monothioglycerol (5 mg/mL); citric and hydrochloric acids are added to adjust pH. It has a relatively low viscosity.

Tulathromycin may also be known as tulathromycine, tulathromycinum, CP-472295 (component A), CP-547272 (component B), or *Draxxin*®.

Storage/Stability/Compatibility

Tulathromycin injection should be stored at, or below 25°C (77°F). The product is stable at room temperature for up to 36 months.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tulathromycin Injection 100 mg/mL in 50, 100, 250, & 500 mL vials: *Draxxin*® (Pfizer); Approved for use in cattle and swine. Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in pre-ruminating calves. Do not use in calves to be processed for veal.

Swine intended for human consumption must not be slaughtered within 5 days from the last treatment.

HUMAN-LABELED PRODUCTS: None

TYLOSIN

(tye-loe-sin) Tylan®

MACROLIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Macrolide antibiotic related to erythromycin, used primarily in cattle & swine; sometimes used orally in cats/dogs for chronic colitis
- ▶ Contraindications: hypersensitivity to it or other macrolide antibiotics; probably contraindicated in horses
- ▶ Adverse Effects: Pain & local reactions after IM injection, GI upset (anorexia, & diarrhea). May cause severe diarrheas if administered PO to ruminants or by any route to horses. **SWINE:** edema of rectal mucosa & mild anal protrusion with pruritus, erythema, & diarrhea

Uses/Indications

Although the injectable form of tylosin is approved for use in dogs and cats, it is rarely used parenterally in those species. Oral tylosin is sometimes recommended for the treatment of chronic colitis in small animals (see Doses), but controlled studies documenting its efficacy have not been performed.

Tylosin is also used clinically in cattle and swine for infections caused by susceptible organisms.

Pharmacology/Actions

Tylosin is thought to have the same mechanism of action as erythromycin (binds to 50S ribosome and inhibits protein synthesis) and exhibits a similar spectrum of activity. It is a bacteriostatic antibiotic. Tylosin may also have immunomodulatory effects on cell-mediated immunity. In dogs, tylosin increases concentrations of enterococci (*Enterococcus faecalis*) in the jejunum. Enterococci are thought to have probiotic effects.

For more specific information on organisms where tylosin is usually active, refer to the erythromycin monograph; cross-resistance with erythromycin occurs.

Pharmacokinetics

Tylosin tartrate is well absorbed from the GI tract, primarily from the intestine. The phosphate salt is less well absorbed after oral administration. Tylosin base injected SC or IM is reportedly rapidly absorbed.

Like erythromycin, tylosin is well distributed in the body after systemic absorption, with the exception of penetration into the CSF. The volume of distribution of tylosin is reportedly 1.7 L/kg in small animals and 1–2.3 L/kg in cattle. In lactating dairy cattle, the milk to plasma ratio is reported to be between 1–5.4.

Tylosin is eliminated in the urine and bile apparently as unchanged drug. The elimination half-life of tylosin is reportedly 54 minutes in small animals, 139 minutes in newborn calves, and 64 minutes in calves 2 months of age or older.

Contraindications/Precautions/Warnings

Tylosin is contraindicated in patients hypersensitive to it or other macrolide antibiotics (e.g., erythromycin). Most clinicians feel that tylosin is contraindicated in horses, as severe and sometimes fatal diarrheas may result from its use in that species.

Adverse Effects

Most likely adverse effects with tylosin are pain and local reactions at intramuscular injection sites, and mild GI upset (anorexia and diarrhea). Tylosin may induce severe diarrheas if administered orally to ruminants or by any route to horses. In swine, adverse effects reported include edema of rectal mucosa and mild anal protrusion with pruritus, erythema, and diarrhea.

Reproductive/Nursing Safety

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Overdosage/Acute Toxicity

Tylosin is relatively safe in most overdose situations. The LD₅₀ in pigs is greater than 5 g/kg orally, and approximately 1 g/kg IM. Dogs are reported to tolerate oral doses of 800 mg/kg. Long-term (2 year) oral administration of up to 400 mg/kg produced no organ toxicity in dogs. Shock and death have been reported in baby pigs overdosed with tylosin, however.

Drug Interactions

Drug interactions with tylosin have not been well documented. It has been suggested that tylosin may increase **digoxin** blood levels with resultant toxicity. It is suggested to refer to the erythromycin monograph for more information on potential interactions.

Laboratory Considerations

- Macrolide antibiotics may cause falsely elevated values of **AST** (SGOT), and **ALT** (SGPT) when using colorimetric assays.
- Fluorometric determinations of **urinary catecholamines** can be altered by concomitant macrolide administration.

Doses

■ DOGS:

When using *Tylan*® Soluble (100 grams per bottle) powder: Using volumetric containers to measure powders is not necessarily accurate, but 1 level teaspoonful (5 mL) of powder contains approximately 2.5–2.7 grams of tylosin; 1/8th of a teaspoonful contains approximately 325 mg tylosin.

- a) For small intestinal bacterial overgrowth: 10–20 mg/kg PO q12h; recommended for chronic cases, may require therapy for as long as 6 weeks. (Ludlow and Davenport 2000)
- b) For adjunctive treatment of IBD: 10 mg/kg PO three times daily. Therapeutic trial for 21 days to evaluate efficacy. (Simpson 2003a)

- c) For clostridial colitis: 10–40 mg/kg PO twice daily. Practically (using the wettable powder): $\frac{1}{16}$ th of teaspoon 2–3 times daily for dogs (<7kg); $\frac{1}{8}$ th of a teaspoon 2–3 times a day for medium dogs (7–15 kg); and $\frac{1}{4}$ teaspoon 2–3 times a day for larger dogs (>15 kg). Mix with food to hide unpleasant taste or put into capsules. Animals with chronic clostridial colitis can often be controlled with one treatment every 2–3 days. (Willard 2006a)
- d) For IBD and antibiotic responsive diarrhea: 20–40 mg/kg PO q12h (Marks 2007b)

■ CATS:

When using *Tylan® Soluble* (100 grams per bottle) powder: Using volumetric containers to measure powders is not necessarily accurate, but 1 level teaspoonful (5 mL) of powder contains approximately 2.5–2.7 grams of tylosin; $\frac{1}{8}$ th of a teaspoonful contains approximately 325 mg tylosin.

- a) For adjunctive treatment of IBD: 10 mg/kg PO three times daily. Therapeutic trial for 21 days to evaluate efficacy. (Simpson 2003a)
- b) For treatment of IBD or diarrheas caused by *C. perfringens*: 20–40 mg/kg PO twice daily (Marks 2002)
- c) For IBD: 40 mg/kg PO q12h (Zoran 2007)
- d) For clostridial colitis: 10–40 mg/kg PO twice daily. Practically (using the wettable powder): $\frac{1}{16}$ th of teaspoon 2–3 times daily. Mix with food to hide unpleasant taste or put into capsules. Animals with chronic clostridial colitis can often be controlled with one treatment every 2–3 days. (Willard 2006a)

■ FERRETS:

For susceptible infections:

- a) 10 mg/kg PO once to twice daily (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 10 mg/kg PO, SC, IM q12–24h (Ivey and Morrissey 2000)
- b) Gerbils, Hamsters, Rats: 10 mg/kg SC q24h (Adamcak and Otten 2000)

■ CATTLE:

For susceptible infections:

- a) 17.6 mg/kg IM once daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 5 days. Do not inject more than 10 mL per site. Use the 50 mg/mL formulation in calves weighing less than 200 pounds. (Package insert; *Tylosin® Injection*—TechAmerica)
- b) For bronchopneumonia and fibrinous pneumonia in cattle associated with penicillin G-refractory *C. pyogenes* infections or other bacteria sensitive to tylosin and resistant to sulfas, penicillin G and tetracyclines: using Tylosin 200 mg/mL: 44 mg/kg IM q24h. Recommend a 21-day slaughter withdrawal at this dosage. (Hjerpe 1986)
- c) 5–10 mg/kg IM or slow IV once daily; not to exceed 5 days (Huber 1988a)
- d) Tylosin base injectable: 10 mg/kg IM initially, then 6 mg/kg IM q8h (q8–12h in calves) (Baggot 1983)

■ SWINE:

For susceptible infections:

- a) 8.8 mg/kg IM twice daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 3 days. Do not inject more than 5 mL per site. (Package insert; *Tylosin® Injection*—TechAmerica)

- b) 5–10 mg/kg until 24 hours after remission of disease signs; not to exceed 3 days therapy (Huber 1988a)
- c) Tylosin base injectable: 12.5 mg/kg IM q12h (Baggot 1983)

■ SHEEP & GOATS:

For susceptible infections:

- a) 10 mg/kg, treatment not to exceed 5 days (Huber 1988a)

■ BIRDS:

For susceptible infections:

- a) For initial therapy in caged birds for upper respiratory infections (especially if mycoplasma suspected). Using 200 mg/mL injectable: 40 mg/kg IM. Used in combination with aminoglycosides. (McDonald 1989)
- b) For initial therapy of upper respiratory infections and air sacculitis. Using 50 mg/mL or 200 mg/mL injectable: 10–40 mg/kg IM twice daily or three times daily (Clubb 1986)
- c) 30 mg/kg IM q12h (Hoeffer 1995)

■ REPTILES:

For susceptible infections:

- a) For tortoises: 5 mg/kg IM once daily for at least 10 days. Used primarily for chronic respiratory infections or when Mycoplasma is suspected (Gauvin 1993)
- b) All species: 5 mg/kg IM once daily (Jacobson 1999)

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

A macrolide antibiotic related structurally to erythromycin, tylosin is produced from *Streptomyces fradiae*. It occurs as an almost white to buff-colored powder with a pK_a of 7.1. It is slightly soluble in water and soluble in alcohol. Tylosin is considered highly lipid soluble. The tartrate salt is soluble in water. The injectable form of the drug (as the base) is in a 50% propylene glycol solution.

Tylosin may also be known as Desmycosin, tilosina, tylozin, tylosini, tylosinum, tylozyna or *Tylan®*.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, injectable tylosin should be stored in well-closed containers at room temperature. Tylosin, like erythromycin, is unstable in acidic (pH <4) media. It is not recommended to mix the parenteral injection with other drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Note: The product *Tylan® Plus Vitamins* was used extensively orally in companion animals, but has been withdrawn from the market. *Tylan® Soluble* may be substituted, but is significantly more concentrated than *Tylan® Plus Vitamins* and dosage sizes (teaspoons are not equivalent) will be different.

Tylosin Injection: 50 mg/mL, 200 mg/mL; *Tylan®* (Elanco); generic; (OTC). Approved for use in nonlactating dairy cattle, beef cattle, swine, dogs, and cats. Slaughter withdrawal (at labeled doses): cattle = 21 days; swine = 14 days. **Note:** Although this author (Plumb) was unable to locate parenteral products approved for use in lactating dairy animals, one source (Huber 1988a) states that tylosin has a 72 hour milk withdrawal for dairy cattle, and 48 hour milk withdrawal in dairy goats and sheep. Contact FARAD for more information before using in lactating dairy animals.

Tylosin Tartrate Powder: (approximately 2.5–2.7 grams/level teaspoonsful) in 100 g bottles; *Tylan® Soluble* (Elanco); (OTC). Approved for use in turkeys (not layers), chickens (not layers) and swine. Slaughter withdrawal swine = 2 days; chickens = 1 day; turkeys = 5 days.

There are many approved tylosin products for addition to feed or water for use in beef cattle, swine, and poultry. Many of these products have other active ingredients included in their formulations.

HUMAN-LABELED PRODUCTS: None.

URSODIOL

(ur-soe-dye-ole) Actigall®, Ursodeoxycholic acid

BILE ACID

Prescriber Highlights

- ▶ Bile acid that may be useful for treatment of hepatobiliary disease in dogs/cats. May also be used for cholesterol containing gallstones
- ▶ Contraindications: Rabbits & other hindgut fermenters. Caution: Complications associated with gallstones (e.g., biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis)
- ▶ Adverse Effects: Appears to be well tolerated in dogs/cats

Uses/Indications

In small animals, ursodiol may be useful as adjunctive therapy for the medical management of cholesterol-containing gallstones and/or in patients with chronic liver disease, particularly where cholestasis (bile toxicity) plays an important role. Ursodiol's benefit in treating canine or feline hepatobiliary disease is unknown at the time of writing (studies are ongoing), but it may be of help in slowing the progression of inflammatory hepatic disorders, particularly autoimmune hepatitis and acute hepatotoxicity.

Pharmacology/Actions

After oral administration, ursodiol suppresses hepatic synthesis and secretion of cholesterol. Ursodiol also decreases intestinal absorption of cholesterol. By reducing cholesterol saturation in the bile, it is thought that ursodiol allows solubilization of cholesterol-containing gallstones. Ursodiol also increases bile flow and in patients with chronic liver disease, it apparently reduces the hepatocyte toxic effects of bile salts by decreasing their detergent action, and may protect hepatic cells from toxic bile acids (e.g., lithocholate, deoxycholate, and chenodeoxycholate).

Pharmacokinetics

Ursodiol is well absorbed from the small intestine after oral administration. In humans, up to 90% of dose is absorbed. After absorption, it enters the portal circulation. In the liver, it is extracted and combined (conjugated) with either taurine or glycine and secreted into the bile. Only very small quantities enter the systemic circulation and very little is detected in the urine. After each entero-hepatic cycle, some quantity of conjugated and free drug undergoes bacterial degradation; eventually most of the drug is eliminated in the feces after being oxidized or reduced to less soluble compounds. Ursodiol detected in the systemic circulation is highly bound to plasma proteins.

Contraindications/Precautions/Warnings

Ursodiol is contraindicated in rabbits and other hindgut fermenters as it is converted into lithocholic acid (toxic). Patients sensitive to other bile acid products may also be sensitive to ursodiol. The benefits of using ursodiol should be weighed against its risks in patients with complications associated with gallstones (e.g., biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis). While ursodiol may be useful in treating patients with chronic liver disease, some patients may experience further impairment of bile acid metabolism.

Adverse Effects

While ursodiol use in animals has been limited, it appears to be well tolerated in dogs and cats. Although hepatotoxicity has not been associated with ursodiol therapy, some human patients have an inability to sulfate lithocholic acid (a naturally occurring bile acid and also a metabolite of ursodiol). Lithocholic acid is a known hepatotoxin; veterinary significance is unclear. Diarrhea and other GI effects have rarely been noted in humans taking ursodiol. Ursodiol will not dissolve calcified radiopaque stones or radiolucent bile pigment stones.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether ursodiol is excreted in breast milk.

Overdosage/Acute Toxicity

Overdosage of ursodiol would most likely cause diarrhea. Treatment, if required, could include supportive therapy; oral administration of an aluminum-containing antacid (e.g., aluminum hydroxide suspension); gastric emptying (if large overdose) with concurrent administration of activated charcoal or cholestyramine suspension.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ursodiol and may be of significance in veterinary patients:

- **ALUMINUM-CONTAINING ANTACIDS:** May bind to ursodiol, thereby reducing its efficacy
- **CHOLESTYRAMINE RESIN:** May bind to ursodiol, thereby reducing its efficacy

Laboratory Considerations

- As ursodiol is detected by many **serum bile acid** tests, bile acids may remain falsely elevated. One study in normal dogs did not show any effects, however.

Doses

■ DOGS:

For adjunctive treatment of chronic hepatitis:

- a) 5–15 mg/kg PO divided q12h, with immunosuppressive therapy. (**Note:** Use of this drug at this dose is preliminary, but promising) (Johnson and Sherding 1994)
- b) 10–15 mg/kg PO once daily (Leveille-Webster and Center 1995); (Twedt 1999)
- c) For use in chronic active hepatitis, fibrosis and cirrhosis. May use as primary or adjunctive therapy. Dose: 11–15.4 mg/kg PO either once daily or divided twice daily (Tams 2000)

■ **CATS:**

For adjunctive treatment of chronic hepatitis:

- a) 10–15 mg/kg PO once daily (Leveille-Webster and Center 1995); (Trepanier 1999)
- b) For use in chronic active hepatitis, fibrosis, and cirrhosis. May use as primary or adjunctive therapy. Dose: 11–15.4 mg/kg PO either once daily or divided twice daily. Cats usually get 1/6th of a capsule mixed with a small amount of food. Cats may still eat their food even if drug is sprinkled on top. (Tams 2000)
- c) 10 mg/kg/day PO (Zoran 2006b)

■ **Monitoring**

- Efficacy (ultrasonography for gallstones; improved liver function tests for chronic hepatic disease)
- Monitoring of SGPT/SGOT (AST/ALT) on a routine basis (in humans these tests are recommended to be performed at the initiation of therapy and at 1 and 3 months after starting therapy; then every 6 months).

■ **Client Information**

- Because ursodiol dissolves more rapidly in the presence of bile or pancreatic juice, it should be given with food.

■ **Chemistry/Synonyms**

A naturally occurring bile acid, ursodiol, also known as ursodeoxycholic acid has a molecular weight of 392.6.

Ursodiol may also be known as: acidum ursodeoxycholicum, UDCA, ursodesoxycholic acid; many trade names are available.

■ **Storage/Stability**

Unless otherwise specified by the manufacturer, ursodiol capsules should be stored at room temperature (15–30°C) in tight containers.

■ **Dosage Forms/Regulatory Status**

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ursodiol Capsules: 300 mg; *Actigall*® & generic (Watson); (Rx)

Ursodiol Tablets: 250 mg & 500 mg; *URSO*® 250 & *-Forte* (Axcen Pharma); (Rx)

VALPROIC ACID VALPROATE SODIUM DIVALPROEX SODIUM

(*val-proe-ik*; *val-proe-ayte*; *die-val-proe-ex*)

Depakene®, Depakote®, Depacon®

Prescriber Highlights

- ▶ 2nd to 4th line anticonvulsant that may be useful as adjunctive treatment in some dogs; most do not recommend its use in veterinary patients
- ▶ Contraindications: Significant hepatic disease or dysfunction, previous hypersensitivity
- ▶ Caution: Thrombocytopenia or altered platelet aggregation function
- ▶ Adverse Effects: GI effects (may be diminished by giving with food) most likely; hepatotoxicity, CNS (sedation, ataxia, behavioral changes, etc.), dermatologic reactions, (alopecia, rash, etc.), hematologic reactions, (thrombocytopenia, reduced platelet aggregation, leukopenias, anemias, etc.), pancreatitis, & edema are possible
- ▶ May be teratogenic

Uses/Indications

Because of its cost, apparent unfavorable pharmacokinetic profile, and potential hepatotoxicity, valproic acid must be considered at best, a third or fourth line drug in the treatment of seizures in the dog. Some clinicians feel it is of benefit when added to phenobarbital in patients not adequately controlled with that drug alone. Additionally, it is less protein bound in dogs than in humans, so the human serum therapeutic range of the drug (40–100 mcg/mL) may be too high in dogs. The drug (free form) actually may concentrate in the CSF, and anticonvulsant effects may persist even after valproate levels are non-detectable in CSF, lending to the idea that serum levels do not accurately reflect clinical efficacy. Clearly, additional studies are needed to determine the clinical role, if any, for this drug.

Pharmacology/Actions

The mechanism of the anticonvulsant activity of valproic acid is not understood. Animal studies have demonstrated that valproic acid inhibits GABA transferase and succinic aldehyde dehydrogenase causing increased CNS levels of GABA. Additionally, one study has demonstrated that valproic acid inhibits neuronal activity by increasing potassium conductance.

Pharmacokinetics

Sodium valproate is rapidly converted to valproic acid in the acidic environment of the stomach where it is rapidly absorbed from the GI tract. The bioavailability reported in dogs following oral administration is approximately 80%; peak levels occur in approximately 1-hour. Food may delay absorption, but does not alter the extent of it. Divalproex in its enteric-coated form has an approximately 1-hour delay in its oral absorption. Patients' who exhibit GI (nausea, vomiting) adverse effects may benefit from this dosage form.

Valproic acid is rapidly distributed throughout the extracellular water spaces and plasma. It is approximately 80–95% plasma protein bound in humans, and 78–80% plasma protein bound in

dogs. CSF levels are approximately 10% those found in plasma. Milk levels are 1–10% those found in plasma; it readily crosses the placenta.

Valproic acid is metabolized in the liver and is conjugated with glucuronide. These metabolic conjugates are excreted in the urine; only very small amounts of unchanged drug are excreted in the urine. The elimination half-life in humans ranges from 5–20 hours; in dogs from 1.5–2.8 hours.

Contraindications/Precautions/Warnings

Valproic acid is contraindicated in patients with significant hepatic disease or dysfunction, or exhibiting previous hypersensitivity to the drug. It should be used with caution in patients with thrombocytopenia or altered platelet aggregation function.

Adverse Effects

Because of the limited experience with this agent, the following adverse effects may not be complete nor valid for dogs: Gastrointestinal effects consisting of nausea, vomiting, anorexia, and diarrhea are the most common adverse effects seen in people and also apparently, in dogs. GI effects may be diminished by administration with food. Hepatotoxicity is the most serious potential adverse (human) reaction reported and must be considered for canine patients also. Dose related increases in liver enzymes may be seen and, rarely, hepatic failure and death may occur. In humans, incidences of hepatotoxicity are greater in very young (<2 yr. old) patients, those on other anticonvulsants, or with multiple congenital abnormalities.

Other potential adverse effects include: CNS (sedation, ataxia, behavioral changes, etc.), dermatologic (alopecia, rash, etc.), hematologic (thrombocytopenia, reduced platelet aggregation, leukopenias, anemias, etc.), pancreatitis, and edema.

Reproductive/Nursing Safety

A 1–2% incidence of neural tube defects in children born of mothers taking valproic acid during the first trimester of pregnancy has been reported. Use in pregnant dogs only when the benefits outweigh the risks of therapy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Concentrations of valproic acid in maternal milk are 1–10% of serum concentrations. It is unknown if this would have any detrimental effect on nursing offspring.

Overdosage/Acute Toxicity

Severe overdoses can cause profound CNS depression, asterixis, motor restlessness, hallucinations, and death. One human patient recovered after a serum level of 2000 micrograms/mL (20 times over therapeutic) was measured. Treatment consists of supportive measures and maintenance of adequate urine output is considered mandatory. Because the drug is rapidly absorbed, emesis or gastric lavage may be of limited value. Because of its delayed absorptive characteristics, the divalproex form may be removed by lavage or emesis if ingestion occurred recently. Naloxone is reported to be of benefit in reversing some of the CNS effects of valproic acid, but may also reverse the anticonvulsant properties of the drug.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving valproic acid and may be of significance in veterinary patients:

- **ANTICOAGULANTS:** Valproic acid may have effects on platelet aggregation; use with caution with other drugs that affect coagulation status
- **ASPIRIN:** Salicylates may displace valproic acid from plasma protein sites, thus increasing valproic acid levels
- **CLONAZEPAM:** The sedative effects of clonazepam may be enhanced by valproic acid and the anticonvulsant efficacy of both may be diminished
- **CNS DEPRESSANTS, OTHER:** VPA may enhance the CNS depressant effects of other CNS active drugs.
- **PHENOBARBITAL, PRIMIDONE:** Valproic acid may increase serum levels of phenobarbital and primidone

Laboratory Considerations

- A keto-metabolite of valproic acid is excreted into the urine and may yield false positive **urine ketone** tests.
- Altered **thyroid function tests** have been reported in humans with unknown clinical significance.

Doses

Note: Because of its very short half-life in dogs, most neurologists do not recommend using VPA in dogs.

■ DOGS:

- a) Add on therapy with phenobarbital or bromide: 60 mg/kg PO q8h (Thomas 2000)

Monitoring

- Anticonvulsant efficacy
- If used chronically, routine CBC's and liver enzymes at least every 6 months

Client Information

- Compliance with therapy must be stressed to clients for successful epilepsy treatment. Encourage administering daily doses at same time each day, preferably with food.
- Veterinarian should be contacted if animal develops significant adverse reactions (including clinical signs of anemia and/or liver disease) or if seizure control is unacceptable.

Chemistry/Synonyms

Structurally unrelated to other anticonvulsant agents; valproic acid, valproate sodium, divalproex sodium are derivatives of carboxylic acid. Valproic acid occurs as a colorless to pale yellow clear liquid. It is slightly viscous; has a characteristic odor, a pK_a of 4.8, is slightly soluble in water and freely soluble in alcohol. It is also known as Dipropylacetic acid, DPA, 2-propylpentanoic acid, and 2-propylvaleric acid.

Valproate sodium occurs as a white, crystalline, saline tasting, very hygroscopic powder. It is very soluble in water or alcohol. The commercially available oral solution has a pH of 7–8.

Divalproex sodium is a stable compound in a 1:1 molar ratio of valproic acid and valproate sodium. It occurs as a white powder with a characteristic odor. It is insoluble in water and very soluble in alcohol.

Valproate sodium may also be known as: Abbott-44090, natrii valproas; many trade names are available.

Valproic acid may also be known as: Abbott-44089, acidum valproicum; many trade names are available.

Storage/Stability

Valproic acid capsules should be stored at room temperature (15–30°C) and in tight containers; avoid freezing. Valproate sodium oral solution should be stored at room temperature and in tight containers; avoid freezing. Divalproex sodium enteric-coated tablets should be stored at room temperature in tight, light resistant containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Valproic Acid Capsules: 250 mg; *Depakene*® (Abbott); (Rx); generic; (Rx)

Valproate Sodium Syrup: 50 mg/mL in 473 mL; *Depakene*® (Abbott); generic; (Rx)

Divalproex Sodium Delayed/Extended Release Tablets: 125 mg, 250 mg, 500 mg; *Depakote*® and *Depakote ER*® (Abbott); (Rx)

Divalproex Sodium Capsules (Sprinkle): 125 mg; *Depakote*® (Abbott); (Rx)

Valproate Sodium Injection: 100 mg/mL in 5 mL single-dose vials (regular and preservative free); *Depacon*® (Abbott); generic; (Bedford); (Rx)

VANADIUM VANADYL SULFATE

(van-aye-dee-um; van-ah-dil) Vanadyl Fuel®

TRACE METAL

Prescriber Highlights

- ▶ Trace metal “nutraceutical” that may be useful as an adjunctive treatment for diabetes mellitus in cats
- ▶ Efficacy questionable, but probably safe

Uses/Indications

Vanadium supplementation may be useful in the adjunctive treatment of diabetes mellitus, particularly in cats. There is controversy whether or not this treatment is beneficial.

Pharmacology/Actions

In humans with non-insulin dependent diabetes mellitus (NIDDM), vanadium can reduce fasting blood glucose and glycosylated hemoglobin levels, reduces hepatic glucose release, and increases peripheral glucose disposal and uptake into skeletal muscle mediated by insulin. Vanadium does not influence blood glucose levels in normal patients. While the exact mechanism of action of vanadium is unknown, it apparently inhibits protein tyrosine phosphatase (PTP). PTP is important in signal transduction and allows vanadium to act via both insulin-dependent and insulin-independent pathways.

Pharmacokinetics

Little information on the pharmacokinetics of vanadium was located. Only about 5% is absorbed from foodstuffs. *In vivo* it is converted to the vanadyl cation and forms complexes with ferritin and transferrin. Highest vanadium concentrations are found in the liver, bone and kidney. Vanadium is eliminated via renal routes. Effects on glucose in NIDDM humans may persist for weeks after discontinuation of therapy.

Contraindications/Precautions/Warnings

Vanadium supplements could potentially exacerbate renal insufficiency; use with caution in these patients.

Adverse Effects

Gastrointestinal effects have been reported in some cats receiving vanadium supplements; anorexia and vomiting is most commonly reported. It has been reported that cats initially unable to tolerate vanadium, can have therapy re-instituted without ill effect. Vanadium in high dosages may have renal toxic effects.

Reproductive/Nursing Safety

It is unknown if supplemental vanadium is safe in pregnancy.

Vanadium is unlikely to have negative effects in nursing kittens.

Overdosage/Acute Toxicity

Vanadyl sulfate may be mildly toxic. The oral LD₅₀ in rats is 450 mg/kg. Consider gut removal protocols if an acute overdose occurs. Contact an animal poison control center for further guidance. Chronic overdoses may cause kidney damage.

Drug Interactions

No specific interactions of note were located. When used with other agents for diabetes management, effects may be additive.

Laboratory Considerations

No specific laboratory interactions or considerations were noted

Doses

Note: Because vanadium is given as a salt, do not confuse dosages for vanadium with vanadyl sulfate. Vanadyl sulfate reportedly contains 31% elemental vanadium, but labeled amounts of vanadium vary considerably.

■ CATS:

- a) Using *Super Vanadyl Fuel*® (Twin Labs; also contains chromium): 1/2 capsule PO once daily with food. (Dowling 2000)
- b) For adjunctive use in treating feline type 2 diabetes: Vanadium (Note: salt not specified, assume elemental vanadium) 0.2 mg/kg PO once daily in food or water. (Greco 2002a)
- c) For diabetes mellitus: Vanadyl sulfate 1 mg/kg PO once daily or vanadium 0.2 mg/kg PO once daily. (Wynn 2002)
- d) For early NIDDM using *Vanadyl Fuel*® (Twin Labs; also contains chromium): One capsule PO once daily (q24h) (Melendez and Lorenz 2002)

Monitoring

- As there is no reliable way to measure vanadium in the body, a clinical trial is the only way to determine whether vanadium is effective in helping to control blood glucose. Standard methods for monitoring efficacy of diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels).

Client Information

- Clients should give the medication only as prescribed and not change brands without their veterinarian's guidance
- Give with food

Chemistry/Synonyms

A trace element, vanadium (V, atomic number 23) is usually given in the form of the inorganic salt, vanadyl sulfate. Vanadyl sulfate occurs as blue crystals and is very soluble in water. Vanadyl sulfate reportedly contains 31% elemental vanadium.

Vanadyl sulfate may also be known as: vanadium (IV) sulfate oxide; vanadium oxysulfate, oxo[sulfato(2-)-O]-vanadium, oxysulfato vanadium (IV); vanadyl (IV) sulfate, or vanadyl (IV)-sulfate hydrate.

Storage/Stability/Compatibility

While vanadyl sulfate is stable under ordinary conditions, refer to the label for each product used.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

No oral products are approved as pharmaceuticals.

Oral vanadyl sulfate products are considered nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by regulatory bodies.

Supplements are available from a wide variety of sources. Common products include 7.5 mg, and 10 mg tablets or 15 mg capsules. One proprietary product that has been used in cats is *Super Vanadyl Fuel*® (Twin Labs). This is a combination product that contains per capsule (among many other ingredients): 150 mcg chromium (from chromium nicotinate and picolinate) and 1.25 mg of elemental vanadium (from BMOV [bi (maltolato) oxovanadium] and vanadyl sulfate). Bioequivalence between products cannot be assumed.

VANCOMYCIN HCL

(van-koe-mye-sin) Vancocin®

GLYCOPEPTIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Glycopeptide antibiotic reserved for IV use for multi-drug resistant Staph or Enterococcus infections; can also be used PO to treat *Clostridium difficile* diarrhea
- ▶ When used systemically, must be given IV; severe pain & tissue injury occurs with SC or IM injection
- ▶ May be synergistic with aminoglycoside therapy, but increased risk of nephrotoxicity, ototoxicity & neutropenia also possible
- ▶ If decreased renal dysfunction, adjust dosage

Uses/Indications

Vancomycin should only be used to treat infections that are documented resistant to other antibiotics and susceptible to vancomycin, usually methicillin-resistant *Staphylococcus* spp. (MRSA) or multidrug-resistant *Enterococcus* spp. It potentially is useful for oral treatment of pseudomembranous colitis caused by *Clostridia difficile*.

Pharmacology/Actions

Vancomycin inhibits cell-wall synthesis and bacterial cell-membrane permeability. It also affects bacterial RNA synthesis. It is only effective against gram-positive bacteria, including many strains of streptococci, staphylococci, and enterococci. Vancomycin is generally a bactericidal antibiotic, but is bacteriostatic against enterococci. Vancomycin also has activity against *Clostridium difficile*, *Listeria monocytogenes*, *Corynebacterium*, and *Actinomyces* spp.. Vancomycin and aminoglycosides can have synergistic action against susceptible bacteria.

Resistance to vancomycin by certain strains of enterococci and staphylococci is an increasing concern in human medicine and potentially, for veterinary patients.

Pharmacokinetics

When given orally, vancomycin is not appreciably absorbed. After intravenous administration, vancomycin is widely distributed. Therapeutic levels can be found in pleural, ascitic, pericardial, and synovial fluids. At usual serum levels, it does not readily distribute into the CSF.

The elimination half-life of vancomycin in patients with normal renal function is approximately 4–6 hours. Prolonged dosing can allow the drug to accumulate. The drug is eliminated primarily via glomerular filtration; small amounts are excreted into the bile.

Contraindications/Precautions/Warnings

Vancomycin is an important antibiotic for treating multi-drug resistant infections in humans. It should not be used in veterinary patients when other antibiotics can be used to successfully treat the infection.

Patients with decreased renal function that require vancomycin should have dosages reduced or dosing interval increased. Serum levels should be monitored.

Adverse Effects

When given parenterally, nephrotoxicity and ototoxicity are the most serious potential adverse effects of vancomycin. Unlike aminoglycosides, these effects are believed to be uncommon. In humans, dermatologic reactions and hypersensitivity can occur; it is unknown if these effects are issues for veterinary patients. Reversible neutropenia has been reported in humans, particularly when dosage is high and prolonged.

Do not administer IV rapidly or as a bolus; thrombophlebitis, severe hypotension or cardiac arrest (rare) have been reported. Vancomycin must be given over at least 30 minutes as a dilute solution.

Do not give IM, SC, or IP. Severe tissue damage and pain may occur.

Oral therapy may cause GI effects (nausea, inappetence).

Reproductive/Nursing Safety

When used orally, vancomycin is relatively safe to use during pregnancy (FDA category *B*). When used IV, it is not known whether vancomycin can cause fetal harm. A limited study performed in humans did not detect fetal harm, but the numbers studied were small. In humans, the FDA categorizes IV vancomycin as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Because in veterinary patients, vancomycin should only be used for serious infections, the potential benefits of therapy will probably outweigh the risks in most circumstances.

Vancomycin is excreted into milk. Because the drug is not appreciably absorbed, it is unlikely to pose significant harm to nursing animals, although diarrhea could occur.

Overdosage/Acute Toxicity

Patients with colitis associated with *Clostridia difficile* taking an oral overdose, could potentially absorb enough drug to cause adverse effects. The IV LD₅₀ for vancomycin in mice and rats is 400 mg/kg and 319 mg/kg, respectively. Intravenous overdoses of vancomycin may cause an increased risk of adverse effects, particularly ototoxicity and nephrotoxicity. Supportive care is advised. Hemodialysis does not appear to remove the drug in significant amounts.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vancomycin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Vancomycin may increase the risk of aminoglycoside-related ototoxicity or nephrotoxicity. Because this combination of drugs may be medically required (there is evidence of synergy against staphylococci and enterococci), only enhanced monitoring is suggested.
- **ANESTHETIC AGENTS:** In children, vancomycin used with anesthetic agents has caused erythema and a histamine-like flushing
- **NEPHROTOXIC DRUGS, OTHER** (e.g., **amphotericin B**, **cisplatin**): Use with caution with other nephrotoxic drugs

Laboratory Considerations

- No specific concerns were noted

Doses

To prepare parenteral solution using vancomycin 500 mg or 1 g powder for injection: Reconstitute the 500 mg for injection vial by adding 10 mL of sterile water for injection. Add 20 mL to the 1 gm vial. Before administering to patient, further dilute reconstituted solutions with (at least 100 mL for 500 mg; 200 mL for 1 gram vial) a compatible diluent (e.g., D₅W, lactated Ringer's, 0.9% NaCl).

■ DOGS:

For susceptible infections:

- a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
- b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003b)
- c) For oral use to treat *C. difficile* enterocolitis: 10–20 mg/kg PO q6h for 5–7 days;
For IV use to treat skin, urinary, soft tissue infections: 10–20 mg/kg IV q12h for 7–10 days;
For IV use to treat systemic infections, bacteremia: 15 mg/kg IV q6h for 10 days. (Greene, Hartmann et al. 2006)

■ CATS:

For susceptible infections:

- a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
- b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003b)

Monitoring

When used parenterally:

- Renal function, baseline and periodic
- Vancomycin levels, maintain trough level above 5 mcg/mL (some say troughs between 10–15 mcg/mL)
- Periodic CBC if therapy is prolonged

Client Information

- Parenteral vancomycin is used in an inpatient setting
- Oral vancomycin may be used for outpatient therapy; clients should be counseled to give as prescribed
- May give oral dosage forms with a small amount of food

Chemistry/Synonyms

A glycopeptide antibiotic, vancomycin HCl occurs as an odorless, tan to brown free-flowing powder. It is freely soluble in water. A 5% aqueous solution has a pH of 2.5–4.5.

Vancomycin may also be known as: vanco, vancomycini, or *Vancocin*®; there are many registered international trade names available.

Storage/Stability/Compatibility

Vancomycin should be stored at room temperature in tight containers that are protected from light. Once reconstituted (see directions in package insert or in the Doses section), the injectable or oral solutions are stable for 14 days if refrigerated. If diluted further with D₅W or sodium chloride 0.9% for parenteral administration, solutions are stable for 24 hours at room temperature and 2 months if refrigerated.

Vancomycin is **compatible** with D₅W, 0.9% NaCl, and lactated Ringer's injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Vancomycin HCl Capsules: 125 mg & 250 mg; *Vancocin*® (ViroPharma); (Rx)

Vancomycin HCl Powder for Oral Solution: 1 gram bottles; generic (ESI Lederle); (Rx)

Vancomycin HCl Powder for Injection: 500 mg, 1, 5, & 10 g; *Vancocin*® (ViroPharma); *Vancoled*® (Lederle); generic (various); (Rx)

VASOPRESSIN

(vay-soe-press-in) Pitressin®

HORMONE

Prescriber Highlights

- ▶ Hormone used primarily as a diagnostic agent & sometimes for treatment of diabetes insipidus; it may be useful for the adjunctive treatment of shock syndromes
- ▶ Contraindications: Chronic nephritis until nitrogen retention is resolved to reasonable levels, or patients hypersensitive to it; Caution: Vascular disease, seizure disorders, heart failure, or asthma
- ▶ Adverse Effects: Local irritation at the injection site (including sterile abscesses), skin reactions, abdominal pain, hematuria, &, rarely, a hypersensitivity (urticarial) reaction
- ▶ Overdosage can lead to water intoxication

Uses/Indications

Vasopressin is used in veterinary medicine as a diagnostic agent and in the treatment of diabetes insipidus in small animals. In recent years, there has been significant interest in using vasopressin for treating shock syndromes in humans and animals. Ongoing research is being conducted.

In human medicine, vasopressin has been used to treat acute GI hemorrhage and to stimulate GI peristalsis. Vasopressin CRI is also being used for treatment of hypotensive septic patients unresponsive to conventional vasopressor. Prior to radiographic procedures, it has been used to disperse interfering gas shadows or help concentrate contrast media.

Pharmacology

Vasopressin or antidiuretic hormone (ADH) promotes the renal reabsorption of solute-free water in the distal convoluted tubules and collecting duct. ADH increases cyclic adenosine monophosphate (cAMP) at the tubule which increases water permeability at the luminal surface resulting in increased urine osmolality and decreased urine flow. Without vasopressin, urine flow can be increased up to 90% greater than normal.

At doses above those necessary for antidiuretic activity, vasopressin can cause smooth muscle contraction. Capillaries and small arterioles are most affected, with resultant decreased blood flow to several systems. Hepatic flow may actually be increased, however.

Vasopressin can cause contraction of smooth muscle of the bladder and gall bladder and increase intestinal peristalsis, particularly of the colon. Vasopressin may decrease gastric secretions and increase GI sphincter pressure; gastric acid concentration remains unchanged.

Vasopressin possesses minimal oxytocic effects, but at large doses may stimulate uterine contraction. Vasopressin also causes the release of corticotropin, growth hormone, and follicle-stimulating hormone (FSH).

Pharmacokinetics

Vasopressin is destroyed in the GI prior to being absorbed and therefore must be administered either intranasally or parenterally. After IM or SC administration in dogs, aqueous vasopressin has antidiuretic activity for 2–8 hours.

Vasopressin is distributed throughout the extracellular fluid. The hormone apparently is not bound to plasma proteins.

Vasopressin is rapidly destroyed in the liver and kidneys. The plasma half-life has been reported to be only 10–20 minutes in humans.

Contraindications/Precautions/Warnings

In humans, vasopressin is contraindicated in patients hypersensitive to it or with chronic nephritis until nitrogen retention is resolved to reasonable levels.

Because of its effects on other systems, particularly at high doses, vasopressin should be used with caution in patients with vascular disease, seizure disorders, heart failure, or asthma.

Adverse Effects

Adverse effects that can be seen include local irritation at the injection site (including sterile abscesses), skin reactions, abdominal pain, hematuria, and, rarely, a hypersensitivity (urticarial) reaction. Overdosage can lead to water intoxication (see below).

Reproductive/Nursing Safety

Although the drug has minimal effects on uterine contractions at usual doses, it should be used with caution in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

Early clinical signs of overdose-induced water intoxication can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures, and eventually death. Treatment for mild intoxication is stopping vasopressin therapy and restricting water access until resolved. Severe intoxication may require the use of osmotic diuretics (mannitol, urea, or dextrose) with or without furosemide.

Drug Interactions

The following drugs may **inhibit** the antidiuretic activity of vasopressin:

- **ALCOHOL**
- **DEMECLOXYCLINE**
- **EPINEPHRINE (large doses)**
- **HEPARIN**
- **NOREPINEPHRINE (large doses)**

The following drugs may **potentiate** the antidiuretic effects of vasopressin:

- **ANTIDEPRESSANTS, TRICYCLIC**
- **CARBAMAZEPINE**
- **CHLORPROPAMIDE**
- **CLOFIBRATE**
- **FLUDROCORTISONE**
- **PHENFORMIN**
- **UREA**

Doses

■ DOGS:

As a diagnostic agent after the water deprivation test (WDT); monitor carefully. The WDT is considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin. Refer to a current small animal internal medicine text for further information.

- a) Exogenous vasopressin test: After WDT, empty bladder and start IV catheter and slowly reintroduce water. Give aqueous vasopressin in D₅W IV at a dose of 2.5 mU/kg over one hour. To make one liter of a 5 mU/mL solution add 5 Units of vasopressin to one liter of D₅W. Empty bladder and collect urine at 30 minutes, 60 minutes, and 90 minutes. If urine specific gravity >1.015 = ADH-responsive DI; if <1.015 = either nephrogenic DI or medullary washout effect. (Nichols and Miller 1988)

For adjunctive treatment of shock:

- a) Dogs with persistent hypotension after optimal fluid therapy; Vasopressin (1–4 microUnits/kg/minute) and/or norepinephrine (0.1–2 mcg/kg/minute). Goal of pressor therapy is to maintain mean arterial blood pressure between 70–90 mmHg. (Hansen 2007a)

For treatment of central diabetes insipidus: **Note:** Because vasopressin tannate in oil is no longer commercially available; most clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.

■ CATS:

As a diagnostic agent after the water deprivation test (WDT): The WDT is generally considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin.

- a) Immediately after the end-point of the WDT, give aqueous vasopressin 0.5 U/kg IM; continue to withhold food and water. At 30, 60, and 120 minutes after vasopressin, empty bladder and determine specific gravity (osmolality). Upon completion, the cat is gradually allowed access to water. Inability to concentrate urine during the water deprivation test followed by a rise in urine specific gravity above 1.025 after vasopressin is indicative of central DI. (Peterson and Randolph 1989)

For treatment of central diabetes insipidus: **Note:** Because vasopressin tannate in oil is no longer commercially available; most

clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.

Monitoring

- Urine output/frequency
- Water consumption
- Urine specific gravity &/or osmolality

Chemistry/Synonyms

A hypothalamic hormone stored in the posterior pituitary, vasopressin is a 9-amino acid polypeptide with a disulfide bond. In most mammals (including dogs and humans), the natural hormone is arginine vasopressin, while in swine the arginine is replaced with lysine. Lysine vasopressin has only about 1/2 the antidiuretic activity of arginine vasopressin. The commercially available vasopressin products may be a combination of arginine or lysine vasopressin derived from natural sources or synthetically prepared. The products are standardized by their pressor activity in rats [USP posterior Pituitary (pressor) Units]; their antidiuretic activity can be variable. Commercially available vasopressin has little, if any, oxytocic activity at usual doses.

Vasopressin injection occurs as a clear, colorless or practically colorless liquid with a faint, characteristic odor. Vasopressin is soluble in water.

Vasopressin may also be known as: ADH, antidiuretic hormone, 8-arginine vasopressin, beta-hypophamine, *Neo-Lidocaton*®, *Pitressin*® or *Pressyn*®.

Storage/Stability/Compatibility

Vasopressin (aqueous) injection should be stored at room temperature; avoid freezing.

If the aqueous injection is to be administered as an intravenous or intra-arterial infusion, it may be diluted in either D5W or normal saline. For infusion use in humans, it is usually diluted to a concentration of 0.1–1 Unit/mL.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Vasopressin Injection: 20 pressor Units/mL in 0.5 mL, 1 mL and 10 mL vials; and 1 mL ampules; *Pitressin*® (Monarch); generic; (Rx)

Vasopressin Tannate Sterile Suspension in oil is no longer commercially available.

Uses/Indications

Vecuronium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation. It causes very minimal cardiac effects and generally does not cause the release of histamine.

Pharmacology/Actions

Vecuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor endplate, thereby inhibiting the effects of acetylcholine. The potency of vecuronium when compared to pancuronium (on a weight basis) has been described as being equipotent to up to 3 times as potent.

Pharmacokinetics

The onset of neuromuscular blockade after IV injection is dependent upon the dose administered. In dogs administered 0.1 mg/kg IV, full neuromuscular block occurs within 2 minutes and the duration of action at this dose is approximately 25 minutes (also receiving halothane anesthesia). Vecuronium has a shorter duration of action than pancuronium (approx. 1/3–1/2 as long), but is very similar to that of atracurium.

Vecuronium is partially metabolized; it and its metabolites are excreted into the bile and urine. Prolonged recovery times may result in patients with significant renal or hepatic disease.

Contraindications/Precautions/Warnings

Vecuronium is contraindicated in patients hypersensitive to it. It should be used with caution in patients with severe renal dysfunction. Lower doses may be necessary in patients with hepatic or biliary disease. Vecuronium has no analgesic or sedative/anesthetic actions. In patients with myasthenia gravis, neuromuscular blocking agents should be used with extreme caution, if at all. One case of successful use in a dog with myasthenia gravis has been reported.

Adverse Effects

In human studies and one limited dog study, adverse effects other than what would be seen pharmacologically (skeletal muscle weakness to profound, prolonged musculoskeletal paralysis) have not been reported.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

No cases of vecuronium overdosage have yet been reported (human or veterinary). Should an inadvertent overdose occur, treat conservatively (mechanical ventilation, O₂, fluids, etc.). Reversal of blockade might be accomplished by administering an anticholinesterase agent (edrophonium, physostigmine, or neostigmine) with an anticholinergic (atropine or glycopyrrolate). A suggested dose for neostigmine is 0.06 mg/kg IV after atropine 0.02 mg/kg IV.

VECURONIUM BROMIDE

(vek-yew-roe-nee-um) Norcuron®

NONDEPOLARIZING
NEUROMUSCULAR BLOCKER

Prescriber Highlights

- ▶ Nondepolarizing neuromuscular blocking agent
- ▶ Contraindications: Hypersensitive to it. Caution: Severe renal dysfunction, hepatic, or biliary disease; extreme caution: myasthenia gravis
- ▶ Adverse Effects: None, other than pharmacologic actions
- ▶ No analgesia or anesthetic effects

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vecuronium and may be of significance in veterinary patients:

- **NON-DEPOLARIZING MUSCLE RELAXANT DRUGS, OTHER:** May have a synergistic effect if used with vecuronium
- **SUCCINYLCHOLINE:** May speed the onset of action and enhance the neuromuscular blocking actions of vecuronium; do not give vecuronium until succinylcholine effects have subsided

The following agents may enhance or prolong the neuromuscular blocking activity of vecuronium:

- **AMINOGLYCOSIDES**
- **ANESTHETICS (halothane, isoflurane, sevoflurane)**
- **CLINDAMYCIN, LINCOMYCIN**
- **DANTROLENE**
- **MAGNESIUM SALTS**
- **PIPERACILLIN, MEZLOCILLIN**
- **QUINIDINE**
- **TETRACYCLINES**
- **VERAPAMIL**

Doses

■ DOGS:

- a) 0.1 mg/kg IV initially (after meperidine and/or acepromazine pre-op 30 minutes before); may give subsequent incremental doses of 0.04 mg/kg IV. Duration of action after initial dose averages 25 minutes. (Jones and Seymour 1985)
- b) 10–20 mcg/kg IV (Morgan 2003)
- c) If using CRI propofol-fentanyl anesthesia: CRI maintenance infusion rate of vecuronium at 0.2 mg/kg/hr;
If using CRI fentanyl-isoflurane or fentanyl-sevoflurane anesthesia: CRI maintenance infusion rate of vecuronium at 0.1 mg/kg/hr. (Nagahama, Nishimura et al. 2006)

■ CATS:

- a) 20–40 mcg/kg (0.02–0.04 mg/kg) IV (Morgan 2003)

Monitoring

- Level of neuromuscular relaxation

Client Information

- This drug should only be used by professionals familiar with its use

Chemistry/Synonyms

Structurally similar to pancuronium, vecuronium bromide is a synthetic, nondepolarizing neuromuscular blocking agent. It contains the steroid (androstane) nucleus, but is devoid of steroid activity. It occurs as white to off-white, or slightly pink crystals or crystalline powder. In aqueous solution, it has a pK_a of 8.97, and the commercial injection has a pH of 4 after reconstitution. 9 mg are soluble in 1 mL of water; 23 mg are soluble in 1 mL of alcohol.

Vecuronium Bromide may also be known as: Org-NC-45, Curlem®, Norcuron®, Rivecrum®, Vecural®, or Vecuron®.

Storage/Stability/Compatibility

The commercially available powder for injection should be stored at room temperature and protected from light. After reconstitution with sterile water for injection, vecuronium bromide is stable for 24 hours at either 2–8°C or at room temperature (less than 30°C) if stored in the original container. As it contains no preservative, unused portions should be discarded after reconstitution. The drug is stable for 48 hours at room temperature or refrigerated when stored

in plastic or glass syringes, but the manufacturer recommends that it be used within 24 hours.

Vecuronium bromide has been shown to be physically **compatible** with D5W, normal saline, D5 in normal saline, and lactated Ringer's.

It should not be mixed with alkaline solutions (e.g., thiobarbiturates).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Vecuronium Bromide Powder for Injection: 10 mg and 20 mg; in 10 mL and 20 mL vials, with and without diluent; *Norcuron*® (Organon); (Rx)

VERAPAMIL HCL

(ver-*ap*-a-mill) Calan®, Isoptin®, Verelan®

CALCIUM-CHANNEL BLOCKER

Prescriber Highlights

- Calcium channel blocking agent used for supraventricular tachycardias in dogs & cats
- Contraindications: Cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia), hypotension, sick sinus syndrome, 2nd or 3rd degree AV block, digoxin intoxication, or hypersensitive to verapamil. IV is contraindicated within a few hours of IV beta-adrenergic blockers.
- Caution: Heart failure, hypertrophic cardiomyopathy, & hepatic or renal impairment. Use very cautiously in patients with atrial fibrillation & Wolff-Parkinson-White (WPW) syndrome.
- Adverse Effects: Hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache, or fatigue
- Drug Interactions

Uses/Indications

Veterinary experience with this agent is somewhat limited, but in dogs and cats verapamil may be useful for supraventricular tachycardias and, possibly, treatment of atrial flutter or fibrillation.

Pharmacology/Actions

A slow-channel calcium blocking agent, verapamil is classified as a class IV antiarrhythmic drug. Verapamil exerts its actions by blocking the transmembrane influx of extracellular calcium ions across membranes of vascular smooth muscle cells and myocardial cells. The result of this blocking is to inhibit the contractile mechanisms of vascular and cardiac smooth muscle. Verapamil has inhibitory effects on the cardiac conduction system and these effects produce its antiarrhythmic properties. Electrophysiologic effects include increased effective refractory period of the AV node, decreased automaticity and substantially decreased AV node conduction. On ECG, heart rate and RR intervals can be increased or decreased; PR and A-H intervals are increased. Verapamil has negative effects on myocardial contractility and decreases peripheral vascular resistance.

Pharmacokinetics

In humans, about 90% of a dose of verapamil is rapidly absorbed after oral administration, but because of a high first-pass effect, only about 20–30% is available to the systemic circulation. Patients with significant hepatic dysfunction may have considerably higher percentages of the drug systemically bioavailable. Food will decrease the rate and extent of absorption of the sustained-release tablets, but less so with the conventional tablets.

Verapamil's volume of distribution is between 4.5–7 L/kg in humans and has been reported to be approximately 4.5 L/kg in dogs. In humans, approximately 90% of the drug in the serum is bound to plasma proteins. Verapamil crosses the placenta and milk levels may approach those in the plasma.

Verapamil is metabolized in the liver to at least 12 separate metabolites, with norverapamil being the most predominant. The majority of the amounts of these metabolites are excreted into the urine. Only 3–4% is excreted unchanged in the urine. In humans, the half-life of the drug is 2–8 hours after a single IV dose, but it can increase after 1–2 days of oral therapy (presumably due to a saturable process of the hepatic enzymes). Serum half-lives of 0.8 hours and 2.5 hours have been reported in the dog.

Contraindications/Precautions/Warnings

Verapamil is contraindicated in patients with cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia amenable to verapamil therapy), hypotension (<90 mmHg systolic), sick sinus syndrome, 2nd or 3rd degree AV block, digoxin intoxication, or hypersensitive to verapamil.

IV verapamil is contraindicated within a few hours of IV beta-adrenergic blocking agents (e.g., propranolol) as they both can depress myocardial contractility and AV node conduction. Use of this combination in patients with wide complex ventricular tachycardia (QRS >0.11 seconds) can cause rapid hemodynamic deterioration and ventricular fibrillation.

Verapamil should be used with caution in patients with heart failure, hypertrophic cardiomyopathy, and hepatic or renal impairment. Toxicity may be potentiated in patients with hepatic dysfunction. It should be used very cautiously in patients with atrial fibrillation and Wolff-Parkinson-White (WPW) syndrome as fatal arrhythmias may result.

Because verapamil may increase blood glucose in dogs, it should be used with caution in diabetic animals.

Verapamil is potentially a neurotoxic substrate of P-glycoprotein; use with caution in those herding breeds (e.g., Collies) that may have the gene mutation that causes a nonfunctional protein.

Adverse Effects

The following adverse reactions may occur: hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache or fatigue.

Reproductive/Nursing Safety

Oral verapamil in rats with doses 1.5–6 times the human dose was embryocidal and retarded fetal growth and development, probably due to reduced weight gains in dams. Verapamil crosses the placenta and can be detected in umbilical vein blood at delivery. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Verapamil is excreted in milk. Consider discontinuing nursing if the dam requires verapamil therapy.

Overdosage/Acute Toxicity

Clinical signs of overdosage may include bradycardia, hypotension, hyperglycemia, junctional rhythms, and 2nd or 3rd degree AV block.

If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered. Treatment is generally supportive in nature; vigorously monitor cardiac and respiratory function. Intravenous calcium salts (1 mL of 10% solution per 10 kgs of body weight) have been suggested to treat the negative inotropic clinical signs, but may not adequately treat clinical signs of heart block. Use of fluids and pressor agents (e.g., dopamine, norepinephrine, etc.) may be utilized to treat hypotensive clinical signs. The AV block and/or bradycardia can be treated with isoproterenol, norepinephrine, atropine, or cardiac pacing. Patients that develop a rapid ventricular rate after verapamil due to antegrade conduction in flutter/fibrillation with WPW syndrome, have been treated with D.C. cardioversion, lidocaine, or procainamide.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving verapamil and may be of significance in veterinary patients:

- **ACE INHIBITORS:** May cause additive hypotensive effects
- **ALPHA-ADRENERGIC BLOCKERS** (e.g., **prazosin**): May cause additive hypotensive effects
- **BETA-ADRENERGIC BLOCKERS** (e.g., **propranolol**): May cause additive negative cardiac inotrope and chronotrope effects
- **DOXORUBICIN:** Verapamil may increase concentrations
- **COPP CHEMOTHERAPY** (cyclophosphamide, vincristine, procarbazine, prednisone): May decrease oral absorption of verapamil
- **CYCLOSPORINE:** Verapamil may increase levels
- **DANTROLENE:** Cardiovascular collapse reported in animals when used with verapamil
- **DIGOXIN:** Verapamil may increase the blood levels of digoxin; monitoring of digoxin levels recommended
- **DISOPYRAMIDE:** May cause additive effects; impair left ventricular function; use together within 24–48 hours not recommended
- **DIURETICS:** May cause additive hypotensive effects
- **ERYTHROMYCIN, CLARITHROMYCIN:** May increase verapamil levels
- **FLECAINIDE:** Possible additive effects; use is together with verapamil is to be avoided in humans
- **NEUROMUSCULAR BLOCKERS:** Neuromuscular blocking effects of nondepolarizing muscle relaxants may be enhanced by verapamil
- **PHENOBARBITAL:** May reduce verapamil levels
- **QUINIDINE:** Additive alpha-adrenergic blocking activity; increased hypotensive effect; verapamil can block quinidine's AV conductive effects and increase quinidine levels
- **RIFAMPIN:** May reduce verapamil levels
- **THEOPHYLLINE:** Verapamil may increase serum levels of theophylline and lead to toxicity
- **VINCISTINE:** Calcium channel blockers may increase intracellular vincristine by inhibiting the drug's outflow from the cell

Laboratory Considerations

- Verapamil may elevate blood glucose in dogs and confuse **blood glucose** determinations

Doses

■ DOGS:

- Initial dose of 0.05 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–2 mg/kg PO q8h (Ware 2000)
- For treatment of hypertension: 1–5 mg/kg PO q8h (Brovida 2002)
- 0.05–0.15 mg/kg slow IV to effect (Fox 2003a)
- 1–5 mg/kg PO three times daily; 0.05–0.25 mg/kg IV slowly (Kramer 2003c)
- For the acute termination of supraventricular tachycardia: Initial dose of 0.05 mg/kg should be administered over 1–2 minutes while ECG is monitored; if not effective, may repeat in 5–10 minutes. If arrhythmia still not terminated, may give one last dose of 0.05 mg/kg (total = 0.15 mg/kg). Effect may persist for 30 minutes or less. For longer control, may give as a CRI at 2–10 mcg/kg/minute. (Kittleson 2006c)

■ CATS:

- Initial dose of 0.025 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–1 mg/kg PO q8h (Ware 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- To control ventricular rate in atrial fibrillation: 0.025–0.05 mg/kg IV q 30 minutes; give less than 0.2 mg/kg total dose (Reimer 2002)

Monitoring

- ECG
- Clinical signs of toxicity (see Adverse Effects);
- Blood pressure, during acute IV therapy
- Serum concentration, if efficacy or toxicity warrant (100–300 ng/mL is considered therapeutic)

Client Information

- To be effective, the animal must receive all doses as prescribed
- If animal becomes lethargic or becomes exercise intolerant, begins wheezing, has shortness of breath or cough, or develops a change in behavior or attitude, notify veterinarian.

Chemistry/Synonyms

A calcium channel blocking agent, verapamil HCl occurs as a bitter-tasting, nearly white, crystalline powder. It is soluble in water and the injectable product has a pH of 4–6.5.

Verapamil HCl tablets should be stored at room temperature (15–30°C); the injectable product should be stored at room temperature (15–30°C) and protected from light and freezing.

Verapamil HCl for injection is physically **compatible** when mixed with all commonly used intravenous solutions. However, a crystalline precipitate may form if verapamil is added to an infusion line with 0.45% sodium chloride with sodium bicarbonate running. Verapamil is reported to be physically **compatible** with the following drugs: amikacin sulfate, aminophylline, ampicillin sodium, ascorbic acid, atropine sulfate, bretylium tosylate, calcium chloride/gluconate, carbenicillin disodium, cefamandole naftate, cefazolin sodium, cefotaxime sodium, cefoxitin sodium, cephalixin sodium, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dexamethasone sodium phosphate, diazepam, digoxin, dobutamine HCl (slight discoloration due to dobutamine oxidation), dopamine HCl, epinephrine HCl, furosemide, gentamicin sulfate, heparin sodium, hydrocortisone sodium phosphate, hydromorphone HCl, insulin, isoproterenol, lidocaine HCl, magnesium sulfate, mannitol, meperidine HCl, metaraminol bitartrate, methi-

cillin sodium, methylprednisolone sodium succinate, metoclopramide HCl, morphine sulfate, multivitamin infusion, nitroglycerin, norepinephrine bitartrate, oxytocin, pancuronium Br, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, phentolamine mesylate, phenytoin sodium, potassium chloride/phosphate, procainamide HCl, propranolol HCl, protamine sulfate, quinidine gluconate, sodium bicarbonate, sodium nitroprusside, ticarcillin disodium, tobramycin sulfate, vasopressin, and vitamin B complex with C.

The following drugs have been reported to be physically **incompatible** with verapamil: albumin injection, amphotericin B, hydralazine HCl, nafcillin sodium, and trimethoprim/sulfamethoxazole. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Verapamil may also be known as: CP-16533-1, D-365, iproveratril hydrochloride, verapamili hydrochloridum; many trade names are available.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Verapamil HCl Tablets: 40 mg, 80 mg & 120 mg; *Calan*® (Searle); generic; (Rx)

Verapamil HCl Sustained/Extended-Release Tablets and Capsules: 100 mg, 120 mg, 180 mg, 200 mg, 240 mg, 300 mg and 360 mg; *Calan*® SR & *Covera-HS*® (Searle); *Isoptin*® SR (Abbott); *Verelan*® and *Verelan*® PM (Schwarz Pharma); generic; (Rx)

Verapamil HCl for Injection: 2.5 mg/mL in 2 mL, and 4 mL vials, amps and syringes, 2 mL fill in single-use *Carpject* syringe; generic; (Rx)

VINBLASTINE SULFATE

(vin-*blas*-teen) Velban®

ANTINEOPLASTIC

Prescriber Highlights

- ▶ A Vinca alkaloid antineoplastic used for a variety of tumors in dogs (& sometimes cats)
- ▶ Contraindications: Preexisting leukopenia or granulocytopenia (unless a result of the disease being treated) or active bacterial infection; reduce dose if hepatic disease
- ▶ Adverse Effects: Gastroenterocolitis (nausea/vomiting), myelosuppression (more so than with vincristine); may also cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw & muscle pain, & loss of deep tendon reflexes
- ▶ CATS can develop neurotoxicity causing constipation or paralytic ileus & aggravating anorexia; can also develop reversible axon swelling & paranodal demyelination
- ▶ Potentially teratogenic
- ▶ Avoid extravasation; wear gloves & protective clothing when preparing or administering
- ▶ Drug Interactions

Uses/Indications

Vinblastine may be employed in the treatment of lymphomas, carcinomas, mastocytomas, and splenic tumors in small animals. It is more effective than vincristine in the treatment of canine mast cell tumors.

Pharmacology/Actions

Vinblastine apparently binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation.

Pharmacokinetics

Vinblastine is administered IV. After injection, it is rapidly distributed to tissues. In humans, approximately 75% is bound to tissue proteins and the drug does not appreciably enter the CNS.

Vinblastine is extensively metabolized by the liver and is primarily excreted in the bile/feces; lesser amounts are eliminated in the urine.

Contraindications/Precautions/Warnings

Vinblastine is contraindicated in patients with preexisting leukopenia or granulocytopenia (unless a result of the disease being treated), or active bacterial infection.

Doses of vinblastine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dl.

Because vinblastine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies) that may have the gene mutation that causes a nonfunctional protein.

As vinblastine may be a skin irritant, gloves and protective clothing should be worn when preparing or administering the medication. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

Adverse Effects

Vinblastine can cause gastroenterocolitis (nausea/vomiting) which generally lasts less than 24-hours. It can be myelosuppressive at usual dosages (nadir at 4–9 days after treatment; recovery at 7–14 days). Vinblastine is considered more myelosuppressive than is vincristine.

Vinblastine may not possess the degree of peripheral neurotoxic effects seen with vincristine, but at high doses, these effects may be seen. Additionally, vinblastine may cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw and muscle pain, and loss of deep tendon reflexes.

Cats can develop neurotoxicity that can be associated with constipation or paralytic ileus thereby aggravating anorexia. They may develop reversible axon swelling and paranodal demyelination.

Extravasation of vinblastine may cause significant tissue irritation and cellulitis. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw the drug from the vial. Should clinical signs of extravasation be noted, discontinue infusion immediately at that site and apply moderate heat to the area to help disperse the drug. Injections of hyaluronidase have also been suggested to help diffuse the drug.

Reproductive/Nursing Safety

Little is known about the effects of vinblastine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males. In humans, the FDA categorizes this drug as category **D** for use during

pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known whether vinblastine is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if dams are being given this drug.

Overdosage/Acute Toxicity

In dogs, the lethal dose for vinblastine has been reported as 0.2 mg/kg. Effects of an overdosage of vinblastine are exacerbations of the adverse effects outlined above. Additionally, neurotoxic effects similar to those associated with vincristine may also be noted.

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants, and prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vinblastine and may be of significance in veterinary patients:

■ **OTOTOXIC DRUGS** (e.g., **cisplatin**, **carboplatin**): May cause additive risk for ototoxicity

Caution is advised if using other drugs that can inhibit **p-glycoprotein** particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”), unless tested “normal”. Drugs and drug classes involved include:

- **AMIODARONE**
- **AZOLE ANTIFUNGALS** (e.g., **ketoconazole**)
- **CARVEDILOL**
- **CYCLOSPORINE**
- **DILTIAZEM**
- **ERYTHROMYCIN; CLARITHROMYCIN**
- **QUINIDINE**
- **SPIRONOLACTONE**
- **TAMOXIFEN**
- **VERAPAMIL**

Laboratory Considerations

■ Vinblastine may significantly increase both blood and urine concentrations of **uric acid**

Doses

For more information on using vinblastine as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology*, 4th Ed. (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine*, 3rd Edition (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline*, 3rd Ed. (Tilley and Smith 2004).

■ DOGS:

For susceptible neoplastic diseases:

- a) 2 mg/m² IV every 7–14 days (O'Keefe and Harris 1990), (Thompson 1989a)
- b) For mast cell tumors after surgical removal: vinblastine at 2 mg/m² IV, weekly for four weeks then every two weeks for

eight weeks. Prednisolone is given concurrently starting at 2 mg/kg/day, tapering to 0.5 mg/kg day. (Davies, Wyatt et al. 2002)

- c) For lymphoma and mastocytoma: 2 mg/m² weekly. For lymphosarcoma and various carcinomas: 2.5 mg/m² IV weekly (MacEwen and Rosenthal 1989), (Rosenthal 1985)

■ CATS:

For susceptible neoplastic diseases:

- a) For lymphosarcoma and mast cell neoplasms: 2 mg/m² IV every 7–14 days (Couto 1989b)
- b) 2 mg/m² slow IV every 7–14 days (Golden and Langston 1988)

Monitoring

- Efficacy
- Toxicity (complete blood counts with platelets; liver function tests prior to therapy and repeated as necessary; serum uric acid)

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Contact the veterinarian if the patient exhibits any symptoms of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising

Chemistry/Synonyms

Commonly referred to as a Vinca alkaloid, vinblastine sulfate is isolated from the plant *Cantharanthus roseus* (*Vinca rosea* Linn) and occurs as a white or slightly yellow, hygroscopic, amorphous or crystalline powder that is freely soluble in water. The commercially available injection has a pH of 3–5.5.

Vinblastine may also be known as: 29060-LE, NSC-49842, sulfato de vimblastina, vinblastini sulfas, vincalukoblastine sulphate, VBL, *Alkaban*®, *Blastovin*®, *Cellblastin*®, *Cytoblastin*®, *Ifabla*®, *Lemblastine*®, *Periblastine*®, *Serovin*®, *Solblastin*®, *Velban*®, *Velbe*®, *Velsar*®, or *Xintoprost*®.

Storage/Stability/Compatibility

The sterile powder for injection, solution for injection and reconstituted powder for injection should all be protected from light. The powder for injection and injection should be stored in the refrigerator (2–8°C). The intact powder for injection is stable at room temperature for at least one month. After reconstituting with bacteriostatic saline, the powder for injection is stable for 30 days if refrigerated.

Vinblastine sulfate is reportedly physically **compatible** with the following intravenous solutions and drugs: D5W and bleomycin sulfate. In syringes or at Y-sites with: bleomycin sulfate, cisplatin, cyclophosphamide, droperidol, fluorouracil, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vincristine sulfate.

Vinblastine sulfate **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: doxorubicin HCl and heparin sodium (in syringes).

Vinblastine sulfate is reportedly physically **incompatible** with furosemide. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Vinblastine Sulfate Injection: 1 mg/mL in 10 mL and 25 mL vials; generic; (Rx)

Vinblastine Powder for Injection: 10 mg in vials; *Velban*® (Lilly); generic; (Rx)

VINCRISTINE SULFATE

(vin-*kris*-teen) Oncovin®

ANTINEOPLASTIC

Prescriber Highlights

- A Vinca alkaloid antineoplastic used for a variety of tumors in dogs & cats (primarily lymphoid & hematopoietic neoplasms); also used for the treatment of immune-mediated thrombocytopenia
- **Caution:** Hepatic disease, leukopenia, infection, or pre-existing neuromuscular disease; reduce dose if hepatic disease
- **Adverse Effects:** Much less myelosuppressive than vinblastine, but may cause more peripheral neurotoxic effects; neuropathic clinical signs can include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation; CATS can develop neurotoxicity causing constipation or paralytic ileus & aggravating anorexia; can also develop reversible axon swelling & paranodal demyelination
- Potentially teratogenic
- Avoid extravasation; wear gloves & protective clothing when preparing or administering
- Drug Interactions

Uses/Indications

Vincristine is used as an antineoplastic primarily in combination drug protocols in dogs and cats in the treatment of lymphoid and hematopoietic neoplasms. In dogs, it may be used alone in the therapy of transmissible venereal neoplasms.

Because vincristine can induce thrombocytosis (at low doses) and has some immunosuppressant activity, it may also be employed in the treatment of immune-mediated thrombocytopenia.

Pharmacology/Actions

Vincristine apparently binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle and urea formation. Tumor resistance to one Vinca alkaloid does not imply resistance to another.

Vincristine can induce thrombocytosis (mechanism unknown) and has some immunosuppressant activity.

Pharmacokinetics

Vincristine is administered IV as it is unpredictably absorbed from the GI tract. After injection it is rapidly distributed to tissues. In humans, approximately 75% is bound to tissue proteins and the drug does not appreciably enter the CNS.

Vincristine is extensively metabolized, presumably by the liver and primarily excreted in the bile/feces; lesser amounts are eliminated in the urine. The elimination half-life in dogs is reportedly biphasic with an alpha half-life of 13 minutes and a beta half-life of 75 minutes.

Contraindications/Precautions/Warnings

Vincristine should be used with caution in patients with hepatic disease, leukopenia, infection, or preexisting neuromuscular disease.

Doses of vincristine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dl.

Because vincristine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies) that may have the gene mutation that causes a nonfunctional protein.

As vincristine may be a skin irritant, gloves and protective clothing should be worn when preparing or administering the medication. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

Adverse Effects

Although structurally related to and having a similar mechanism of action as vinblastine, vincristine has a different adverse reaction profile. Vincristine is much less myelosuppressive (mild leukopenia) at usual doses than is vinblastine, but may cause more peripheral neurotoxic effects. Neuropathic clinical signs may include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation. In humans, vincristine commonly causes mild sensory impairment and peripheral paresthesias. These may also occur in animals, but are not usually noted due to difficulty in detection. Cats, however, can develop neurotoxicity that can be associated with constipation or paralytic ileus thereby aggravating anorexia. They can develop reversible axon swelling and paranodal demyelination.

Additionally, in small animals, vincristine may cause impaired platelet aggregation, increased liver enzymes, inappropriate ADH secretion, jaw pain, alopecia, stomatitis, or seizures.

Extravasation injuries associated with perivascular injection of vincristine can range from irritation to necrosis and tissue sloughing. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw it from the vial. Recommendations of therapy for extravasation include discontinuing the infusion immediately at that site and applying moderate heat to the area to help disperse the drug. Injections of hyaluronidase have been suggested to help diffuse the drug. Others have suggested applying ice to the area to limit the drug's diffusion and minimize the area affected. Topical dimethyl sulfoxide (DMSO) has also been recommended by some to treat the area involved.

Reproductive/Nursing Safety

Little is known about the effects of vincristine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

It is not known whether this drug is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if dams are being given this drug.

Overdosage/Acute Toxicity

In dogs, it is reported that the maximally tolerated dose of vincristine is 0.06 mg/kg every 7 days for 6 weeks. Animals receiving this dose showed signs of slight anemia, leukopenia, increased liver enzymes, and neuronal shrinkage in the peripheral and central nervous systems.

In cats, the lethal dose of vincristine is reportedly 0.1 mg/kg. Cats receiving toxic doses showed clinical signs of weight loss, seizures, leukopenia, and general debilitation.

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants, and prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality. There have been some reports of leucovorin calcium being used to treat vincristine overdoses in humans, but efficacy of this treatment has not yet been confirmed.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vincristine and may be of significance in veterinary patients:

- **ASPARAGINASE:** Additive neurotoxicity may occur; is apparently less common when asparaginase is administered after vincristine
- **MITOMYCIN:** In humans who have previously or simultaneously received mitomycin-C with Vinca alkaloids, severe bronchospasm has occurred

Caution is advised if using other drugs that can inhibit **p-glycoprotein** particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. "white feet"), unless tested "normal". Drugs and drug classes involved include:

- **AMIODARONE**
- **AZOLE ANTIFUNGALS** (e.g., **ketoconazole**)
- **CARVEDILOL**
- **CYCLOSPORINE**
- **DILTIAZEM**
- **ERYTHROMYCIN; CLARITHROMYCIN**
- **QUINIDINE**
- **SPIRONOLACTONE**
- **TAMOXIFEN**
- **VERAPAMIL**

Laboratory Considerations

- Vincristine may significantly increase both blood and urine concentrations of **uric acid**

Doses

For more information on using vincristine as part of chemotherapy protocols such as COP, VELCAP, etc, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

For neoplastic diseases (usually used in combination protocols with other drugs; see the appendix for sample protocols):

- 0.5–0.75 mg/m² IV every 7–14 days (O’Keefe and Harris 1990)
- 0.5 mg/m² every 7–14 days (Coppoc 1988)
- 0.5 mg/m² IV weekly (MacEwen and Rosenthal 1989)
- For transmissible venereal tumor: 0.025 mg/kg (maximum dose 1 mg) IV once weekly. Generally requires 3–6 weeks of therapy. Usually tumor regression noted within 2 weeks of initial treatment. (Herron 1988)
- For transmissible venereal tumor: 0.5 mg/m² (maximum dose 1 mg) IV every 7 days until there is no evidence of disease. Generally requires 4–6 weeks of therapy. (Rosenthal 1985)

For immune-mediated thrombocytopenia:

- Used only when other therapies are ineffective and bone marrow aspirate demonstrates adequate megakaryocytopoiesis: 0.02 mg/kg IV once weekly (Feldman 1989)
- If refractory to prednisone (3–5 days), give vincristine at 0.5–0.7 mg/m² IV bolus or as an infusion over 4–6 hours (Trepanier 1999)
- 0.02 mg/kg IV once; generally single use (Cohn 2004)

■ CATS:

For neoplastic diseases (usually used in combination protocols with other drugs; see the appendix for additional sample protocols):

- 0.5–0.75 mg/m² IV once a week (Couto 1989b)
- For feline lymphoma: A neutrophil count over 4,500 cells/UL is required. Cats should be well hydrated before treatment and fluid therapy should be continued for 24–36 hours. On day 1 give vincristine at 0.5 mg/m² IV and cyclophosphamide at 250 mg/m² IV or orally. These drugs may be administered by slow IV push. If no adverse reactions and neutrophil count is over 4,500, may repeat on day 21. On day 42, premedicate with diphenhydramine (2.2 mg/kg SC) and give doxorubicin at 1 mg/kg IV over 20 minutes into the injection port of an IV drip set. This regimen is repeated until a total of six cycles have been administered. If cat is in complete remission at the end of the 6 cycles, consider stopping therapy. Treatment is delayed if neutropenia or thrombocytopenia occurs. If hemorrhagic cystitis occurs, discontinue cyclophosphamide. Monitor renal function throughout therapy. (Legendre 2003)

Monitoring

- Efficacy (tumor burden reduction or platelet count)
- Toxicity (peripheral neuropathic clinical signs; complete blood counts with platelets; liver function tests prior to therapy and repeated as necessary; serum uric acid)

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Clients should contact the veterinarian if the patient exhibits any signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising, severe constipation, or severe peripheral neuropathic signs

Chemistry/Synonyms

Commonly referred to as a Vinca alkaloid, vincristine sulfate is isolated from the plant *Cantharanthus roseus* (*Vinca rosea* Linn) and occurs as a white or slightly yellow, hygroscopic, amorphous or

crystalline powder that is freely soluble in water and slightly soluble in alcohol. The commercially available injection has a pH of 3–5.5. Vincristine sulfate has pK_{as} of 5 and 7.4

Vincristine Sulfate may also be known as: leurocristine sulfate, VCR, LCR compound 37231, leurocristine sulphate, NSC-67574, 22-oxovincalculeukoblastine sulphate, sulfato de vincristina, vincristini sulfas and *Oncovin*®; many other trade names are available.

Storage/Stability/Compatibility

Vincristine sulfate injection should be protected from light and stored in the refrigerator (2–8°C).

Vincristine sulfate is reportedly physically **compatible** with the following intravenous solutions and drugs: D₅W, bleomycin sulfate, cytarabine, fluorouracil, and methotrexate sodium. In syringes or at Y-sites with: bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin HCl, droperidol, fluorouracil, heparin sodium, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vinblastine sulfate.

Vincristine sulfate is reportedly physically **incompatible** with furosemide. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Vincristine Sulfate Injection: 1 mg/mL in 1 mL, 2 mL and 5 mL vials and flip-top vials; *Vincasar*® PFS (Genesia Sicor); generic; (Rx)

VITAMIN E/SELENIUM VITAMIN E

(se-lee-nee-um)

NUTRITIONAL; FAT SOLUBLE VITAMIN

Prescriber Highlights

- Lipid-soluble vitamin (E) with or without selenium used alone for discoid lupus erythematosus, canine demodicosis, acanthosis nigricans, hepatic fibrosis, or adjunctive therapy of exocrine pancreatic deficiency or hepatopathy in dogs & cats; used in combination for selenium-tocopherol deficiency (white muscle disease)
- Contraindications: Vitamin E/selenium products should only be used in the species for which they are approved
- Selenium overdoses can be extremely toxic
- Adverse Effects: Anaphylactoid reactions; IM injections may cause transient muscle soreness. Selenium OD's can cause depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, & a "garlic" odor on the breath

Uses/Indications

Depending on the actual product and species, vitamin E/selenium is indicated for the treatment or prophylaxis of selenium-tocopherol deficiency (STD) syndromes in ewes and lambs (white muscle disease), sows, weanling and baby pigs (hepatic necrosis, mulberry heart disease, white muscle disease), calves and breeding cows (white muscle disease), and horses (myositis associated with STD).

Vitamin E may be useful as adjunctive treatment of discoid lupus erythematosus, canine demodicosis, and acanthosis nigricans

in dogs. It may also be of benefit in the adjunctive treatment of hepatic fibrosis or adjunctive therapy of copper-associated hepatopathy in dogs.

Pharmacology/Actions

Both vitamin E and selenium are involved with cellular metabolism of sulfur. Vitamin E has antioxidant properties and, with selenium, protects against red blood cell hemolysis and prevents the action of peroxidase on unsaturated bonds in cell membranes.

Pharmacokinetics

After absorption, vitamin E is transported in the circulatory system via beta-lipoproteins. It is distributed to all tissues and stored in adipose tissue. Vitamin E is only marginally transported across the placenta. Vitamin E is metabolized in the liver and excreted primarily into the bile.

Pharmacokinetic parameters for selenium were not located.

Contraindications/Precautions/Warnings

Vitamin E/selenium products should only be used in the species for which they are approved. Because selenium can be extremely toxic, the promiscuous use of these products cannot be condoned.

Give slowly when administering intravenously to horses.

Adverse Effects

Anaphylactoid reactions have been reported. Intramuscular injections may be associated with transient muscle soreness. Other adverse effects are generally associated with overdoses of selenium (see below).

Overdosage/Acute Toxicity

Selenium is quite toxic in overdose quantities, but has a fairly wide safety margin. Cattle have tolerated chronic doses of 0.6 mg/kg/day with no adverse effects (approximate therapeutic dose is 0.06 mg/kg). Clinical signs of selenium toxicity include depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, and a "garlic" odor on the breath. Horses suffering from selenium toxicity may become blind, paralyzed, slough their hooves, and lose hair from the tail and mane. Dogs may exhibit clinical signs of anorexia, vomiting, and diarrhea at high dosages.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vitamin E/selenium and may be of significance in veterinary patients:

- **IRON:** Large doses of vitamin E may delay the hematologic response to iron therapy in patients with iron deficiency anemia.
- **MINERAL OIL:** May reduce the absorption of orally administered vitamin E
- **VITAMIN A:** Absorption, utilization and storage may be enhanced by vitamin E

Doses (Vitamin E alone):

For doses of vitamin E/selenium products see the Dosage Form section

■ DOGS:

For adjunctive treatment of discoid lupus erythematosus, canine demodicosis or acanthosis nigricans:

- a) 200–400 IU PO three times daily; variable efficacy, but relatively innocuous at these dosages (White 2000)

For adjunctive treatment of hepatic fibrosis:

- a) 100–400 IU q12h PO (Rutgers 2000)

For adjunctive treatment of copper-associated hepatopathy:

- a) 400–600 IU PO per day (Johnson 2000)

For treatment of tocopherol deficiency associated with exocrine pancreatic disease:

- a) 100–400 IU PO once daily for one month then every 1–2 weeks as needed (Williams 2000)

■ CATS:

For treatment of tocopherol deficiency associated with exocrine pancreatic disease:

- a) 30 IU PO once daily for one month then every 1–2 weeks as needed (Williams 2000)

For adjunctive treatment of hepatic lipidosis:

- a) 10 IU/kg once PO once daily (Scherk and Center 2005)

■ HORSES:

For adjunctive treatment of ionophore (monensin) toxicity:

- a) 4–12 Units/kg PO once daily (Mogg 1999)

For adjunctive therapy for EPM:

- a) 8000–9000 IU PO per day (Dowling 1999)

For adjunctive therapy for metabolic syndrome:

- a) 10,000 IU PO once daily (Johnson 2003b)

For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):

- a) Foals: 4,000 IU PO once daily; Mares: 10,000 IU PO once daily (Slovic 2003b)

Monitoring

■ Clinical efficacy

■ Blood selenium levels (when using the combination product). Normal values for selenium have been reported as: >1.14 micromol/L in calves, >0.63 micromol/L in cattle, >1.26 micromol/L in sheep, and >0.6 micromol/L in pigs. Values indicating deficiency are: <0.40 micromol/L in cattle, <0.60 micromol/L in sheep, and <0.20 micromol/L in pigs. Intermediate values may result in suboptimal production

■ Optionally, glutathione peroxidase activity may be monitored

Chemistry/Synonyms

Vitamin E is a lipid soluble vitamin that can be found in either liquid or solid forms. The liquid forms occur as clear, yellow to brownish red, viscous oils that are insoluble in water, soluble in alcohol and miscible with vegetable oils. Solid forms occur as white to tan-white granular powders that disperse in water to form cloudy suspensions. Vitamin E may also be known as alpha tocopherol.

Selenium in commercially available veterinary injections is found as sodium selenite. Each mg of sodium selenite contains approximately 460 micrograms (46%) of selenium.

Storage/Stability

Vitamin E/Selenium for injection should be stored at temperatures less than 25°C (77°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Vitamin E (Alone) Injection

Vitamin E Injection: 300 mg/mL in 250 mL vials; *Emulsivit® E-300* (Vedco); *Vital E®-300* (Schering-Plough); (OTC or Rx)

Vitamin E/Selenium Oral

Equ-SeE® (Vet-A-Mix) (one teaspoonful contains 1 mg selenium and 220 IU vitamin E) and *Equ-Se5E®* (one teaspoonful contains 1 mg selenium and approximately 1100 IU vitamin E); (Vet-a-Mix); (OTC) Approved for oral use in horses.

Other top dress equine products containing Vitamin E and Selenium include: Vitamin E and Selenium Powder (Farnam, Horse Health), *Vitamin E and Selenium Crumbles*® (Horse Health)

Vitamin E/Selenium Injection

Mu-Se® (Schering); (Rx): Each mL contains: selenium 5 mg (as sodium selenite); Vitamin E 68 IU; 100 mL vial for injection. Approved for use in non-lactating dairy cattle and beef cattle. Slaughter withdrawal (at labeled doses) = 30 days. Dose: For weanling calves: 1 mL per 200 lbs. body weight IM or SC. For breeding beef cows: 1 mL per 200 lbs. body weight during middle third of pregnancy and 30 days before calving IM or SC.

Bo-Se® (Schering); (Rx): Each mL contains selenium 1 mg (as sodium selenite) and Vitamin E 68 IU; 100 mL vial for injection. Approved for use in calves, swine and sheep. Slaughter withdrawal (at labeled doses) = 30 days (calves); 14 days (lambs, ewes, sows, and pigs). Dose: Calves: 2.5–3.75 mL/100 lbs body weight (depending on severity of condition and geographical area) IM or SC. Lambs (2 weeks of age or older): 1 mL per 40 lbs. body weight IM or SC (1 mL minimum). Ewes: 2.5 mL/100 lbs. body weight IM or SC. Sows and weanling pigs: 1 mL/40 lbs. body weight IM or SC (1 mL minimum). Do not use on newborn pigs.

L-Se® (Schering); (Rx): Each mL contains: selenium 0.25 mg (as sodium selenite) and Vitamin E 68 IU in 30 mL vials. Approved for use in lambs and baby pigs. Slaughter withdrawal (at labeled doses) = 14 days. Dose: Lambs: 1 mL SC or IM in newborns and 4 mL SC or IM in lambs 2 weeks of age or older; Baby Pigs: 1 mL SC or IM.

E-Se® (Schering); (Rx): Each mL contains selenium 2.5 mg (as sodium selenite) and Vitamin E 68 IU in 100 mL vials. Approved for use in horses. Dose: Equine: 1 mL/100 lbs. body weight slow IV or deep IM (in 2 or more sites; gluteal or cervical muscles). May be repeated at 5–10 day intervals.

*Seleto*c® (Schering); (Rx): Each mL contains selenium 1 mg (as sodium selenite) and Vitamin E 68 IU in 10 mL vials. Approved for use in dogs. Dose: Dogs: Initially, 1 mL per 20 pounds of body weight (minimum 0.25 mL; maximum 5 mL) SC, or IM in divided doses in 2 or more sites. Repeat dose at 3 day intervals until satisfactory results then switch to maintenance dose. If no response in 14 days reevaluate. Maintenance dose: 1 mL per 40 lbs body weight (minimum 0.25 mL) repeat at 3–7 day intervals (or longer) to maintain.

HUMAN-LABELED PRODUCTS:

Vitamin E Tablets: 100 IU, 200 IU, 400 IU, 500 IU & 800 IU; generic (various; OTC)

Vitamin E Capsules: 100 IU, 200 IU, 400 IU & 1000 IU; *Mixed E 400 Softgels*® & *d'ALPHA E 1000 Softgels*® (Naturally); *Vita-Plus E*® (Scot-Tussin); generic; (OTC)

Vitamin E Drops: 15 IU/0.3 mL in 12 mL & 30 mL; *Aquasol E*® (Mayne Pharma); *Aquavit-E*® (Cypress); (OTC)

Vitamin E Liquid: 15 IU/30 mL in 30 mL, 60 mL & 120 mL; 798 IU/30 mL in 473 mL; Vitamin E (Freeda); *Nutr-E-Sol*® (Advanced Nutritional Technology); (OTC)

Topicals are available. There are no approved vitamin E/selenium products, but there are many products that contain either vitamin E (alone, or in combination with other vitamins ± minerals) or selenium (as an injection alone or in combination with other trace elements) available.

VORICONAZOLE

(vor-ih-koh-nah-zohl) Vfend®

SECOND GENERATION TRIAZOLE ANTIFUNGAL

Prescriber Highlights

- Broad-spectrum oral/parenteral triazole antifungal
- Very little clinical experience thus far in veterinary medicine; extremely expensive
- Like other compounds in this class, there are many potential drug interactions

Uses/Indications

Voriconazole may be a useful treatment for a variety of fungal infections in veterinary patients, particularly against *Blastomyces*, *Cryptococcus*, and *Aspergillus*. It has high oral bioavailability in a variety of species and can cross into the CNS. Currently available human dosage forms are extremely expensive, however, and little clinical experience has occurred using voriconazole in veterinary patients. There is considerable interest in using voriconazole for treating aspergillosis in pet birds as their relative small size may allow the drug to be affordable; additional research must be performed before dosing regimens are available.

Pharmacology/Actions

Voriconazole a synthetic derivative of fluconazole, has broad-spectrum antifungal activity against a variety of organisms, including *Candida*, *Aspergillus*, *Trichosporon*, *Histoplasma*, *Cryptococcus*, *Blastomyces*, and *Fusarium* species. Like the other azole/triazole antifungals it inhibits cytochrome P-450-dependent 14-alpha-sterol demethylase which is required for ergosterol biosynthesis in fungal cell walls. Unlike fluconazole, voriconazole also inhibits 24-methylene dehydrolanosterol demethylation in molds such as *Aspergillus* giving it more activity against these fungi.

Pharmacokinetics

In dogs, voriconazole is rapidly and essentially completely absorbed after oral administration. Peak levels occur about 3 hours after oral dosing. Voriconazole is only moderately (51%) bound to canine plasma proteins and volume of distribution is about 1.3 L/kg. It is metabolized in the liver to a variety of metabolites with the N-oxide metabolite being the primary circulating metabolite. This metabolite has only weak (<100X as active as the parent) antifungal activity. The elimination pharmacokinetics of voriconazole in dogs is very complex. Both dose-dependent non-linear elimination and auto-induced metabolism after multiple dosages are seen complicating any dosage regimen scenarios; dosages may need to be increased over time. Auto-induction of metabolism apparently does not occur in humans, rabbits or guinea pigs.

In horses, voriconazole is well absorbed after oral administration with peak levels occurring at approximately 3 hours post-dose. Voriconazole has low protein binding (31%); volume of distribution is about 1.35 L/kg. Elimination half-life is quite long—approximately 13 hours after oral dosing. It is not known if voriconazole self-induces hepatic metabolism after multiple doses in the horse.

Contraindications/Precautions/Warnings

Voriconazole is contraindicated in patients hypersensitive to it or other azole antifungals. It should be given with caution to patients with hepatic dysfunction, or proarrhythmic conditions.

The intravenous product contains 3200 mg of sulfobutyl ether beta-cyclodextrin sodium (SBECD) per vial. This compound can accumulate in patients with decreased renal function.

Adverse Effects

Accurate adverse effect profiles are unknown for veterinary species. Liver enlargement and up to a 2–3 fold increase in cytochrome P450 hepatic microsomal enzyme concentrations were noted in dogs orally dosed for 30 days. This may significantly impact the metabolism of other drugs that are hepatically metabolized (See Drug Interactions).

In humans, commonly encountered adverse effects include visual disturbances (blurring, spots, wavy lines) usually within 30 minutes of dosing or if higher drug concentrations are attained, and rashes (usually mild to moderate in severity). Less frequent adverse effects include gastrointestinal effects (nausea, vomiting, diarrhea), hepatotoxicity (jaundice, abnormal liver function tests), hypertension/hypotension, tachycardia, peripheral edema, hypokalemia, and hypomagnesemia. Rarely, eye hemorrhage, anemia, leukopenia, thrombocytopenia, pancytopenia, QT prolongation, torsade de pointes, and nephrotoxicity have been reported.

Reproductive/Nursing Safety

Voriconazole was teratogenic in rats at low dosages (10 mg/kg) and embryotoxic in rabbits at higher dosages (100 mg/kg). In humans, the FDA categorizes voriconazole as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) Weigh the risks of treatment versus the benefits when considering use in pregnant patients.

It is unknown if voriconazole enters milk.

Overdosage/Acute Toxicity

The minimum lethal dose in rats and mice was 300 mg/kg (4–7X maintenance dose). Toxic effects included increased salivation, mydriasis, ataxia, depression, dyspnea, and seizures. Accidental single overdoses of up to 5X in human pediatric patients caused only brief photophobia. No antidote is known for voriconazole overdoses. Gut emptying should be considered for very large oral overdoses, followed by close observation and supportive treatment if required.

Drug Interactions

There are many potential drug interactions involving voriconazole. The following partial listing includes reported or theoretical interactions in humans receiving voriconazole that may also be of significance in veterinary patients. Because, in dogs, voriconazole induces hepatic microsomal enzymes (in humans it does not) additional interactions and further clarification may be reported as clinical use increases in veterinary patients.

- **ANTIDIABETIC AGENTS (sulfonylureas):** Voriconazole may increase serum concentrations of these drugs and increase risk for hypoglycemia
- **BARBITURATES (phenobarbital):** Decreased voriconazole concentrations; use together contraindicated
- **BENZODIAZEPINES:** Voriconazole may increase benzodiazepine concentrations
- **CALCIUM-CHANNEL BLOCKERS (amlodipine, diltiazem, verapamil):** Voriconazole may increase serum concentrations, dosage adjustment may be required
- **CARBAMAZEPINE:** Decreased voriconazole concentrations; use together contraindicated
- **CISAPRIDE:** Potential for serious cardiac arrhythmias; use is contraindicated

- **CORTICOSTEROIDS (prednisolone):** Potentially increased AUC for prednisolone
- **IMMUNOSUPPRESSIVE AGENTS (systemic: cyclosporine, tacrolimus):** Increased cyclosporine and tacrolimus concentrations; decrease cyclosporine dosage by 50% when starting voriconazole; decrease tacrolimus dosage by 33% when starting voriconazole
- **METHADONE:** Voriconazole may increase plasma concentrations of R-methadone; monitor for methadone toxicity and adjust dosage if necessary
- **PHENYTOIN:** Can decrease voriconazole concentrations and voriconazole can increase phenytoin concentrations; monitoring and dosage adjustment may be required
- **PIMOZIDE:** Potential for serious cardiac arrhythmias; use is contraindicated
- **PROTON-PUMP INHIBITORS (omeprazole):** Voriconazole may increase omeprazole (and potentially other PPI's) concentrations
- **QUINIDINE:** Potential for serious cardiac arrhythmias; use is contraindicated
- **RIFAMPIN, RIFABUTIN:** Decreased voriconazole concentrations; use together contraindicated
- **VINCA ALKALOIDS (vincristine, vinblastine):** Possible increased Vinca alkaloid concentrations; monitor for toxicity
- **WARFARIN:** Voriconazole may potentiate warfarin's effects

Laboratory Considerations

No specific concerns were noted; see Monitoring for additional information.

Doses

At the time of writing (March 2007) there is little data or clinical experience with voriconazole to support science- or experience-based dosing regimens for systemic use in veterinary species, particularly in small animals. The drug's pharmacokinetic profile can vary considerably across species and in some species (dogs) the drug induces hepatic microsomal enzymes that increase its own metabolism. A single-dose pharmacokinetic study in horses (Davis, Salmon et al. 2006) gives support to a dose of 4 mg/kg PO once daily for susceptible fungi with an MIC ≤ 1 mcg/mL, but it is unknown if this dose will be adequate after repeated dosing. One respected reference (Greene, Hartmann et al. 2006), has listed a dose for treating fungal infections in dogs extrapolated from the human dose: Loading dose: 6 mg/kg IV or PO q12h for days, then 3–4 mg/kg PO q12h for a duration as necessary.

Monitoring

- Efficacy
- Liver function tests, serum electrolytes

Client Information

- Inform clients of the investigational nature of using this drug in veterinary species and the associated expense
- Give at least one hour before or one hour after feeding
- Because experience with this medication has been limited, report any possible adverse effects to the veterinarian immediately, including itching/rash, yellowing of whites of the eyes, reduced appetite, etc.

Chemistry/Synonyms

A triazole antifungal, voriconazole occurs as a white to light colored powder with a molecular weight of 349.3. Aqueous solubility is 0.7 mg/mL.

Voriconazole may also be known as UK-109496, voriconazol, voriconazolum, or Vfend®.

Storage/Stability/Compatibility

Voriconazole tablets should be stored at 15–30°C.

The unreconstituted powder for oral suspension should be stored in the refrigerator (2–8°C); it has a shelf-life of approximately 18 months. Once reconstituted, it should be stored in tightly closed containers at room temperature (15–30°C); do not refrigerate or freeze. After reconstitution, the suspension is stable for 14 days. The suspension should be shaken well for 10 seconds prior to each administered dose.

The powder for injection should be stored at room temperature (15–30°C). After reconstituting with 19 mL of sterile water for injection, the manufacturer recommends using immediately; however, chemical and physical stability remain for up to 24 hours if stored in the refrigerator (2–8°C). Discard solution if it is not clear or particles are visible.

The injectable solution must be further diluted to a concentration of 5mg/mL or less for administration over 1–2 hours. Suitable diluents for IV infusion include (partial list): NS, LRS, D5LRS, and D5W. Voriconazole is **not compatible** with simultaneous infusion with blood products.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Voriconazole Tablets: 50 mg, 200 mg; *Vfend*® (Pfizer); (Rx)

Voriconazole Powder for Oral Suspension: 45 g (40 mg/mL after reconstitution; orange flavor in 100 mL bottles; *Vfend*® (Pfizer); (Rx)

Voriconazole Powder for Injection, Lyophilized: 200 mg/vial (single use); *Vfend I.V.*® (Pfizer); (Rx). Also contains 3200 mg of sulfobutyl ether beta-cyclodextrin sodium (SBECD) per vial (See Warnings) to solubilize the drug for IV administration.

WARFARIN SODIUM

(war-far-in) Coumadin®

ANTICOAGULANT

Prescriber Highlights

- ▶ Coumarin derivative anticoagulant used primarily for long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in cats, dogs, or horses
- ▶ Contraindications: Preexistent hemorrhage, pregnancy, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, surgery of large, open surfaces, active bleeding from the GI, respiratory, or GU tract; aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, & visceral carcinomas
- ▶ Adverse Effects: Dose-related hemorrhage
- ▶ Teratogenic; contraindicated in pregnancy
- ▶ Must actively monitor coagulation status
- ▶ Drug Interactions

Uses/Indications

In veterinary medicine, warfarin is used primarily for the oral, long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in cats, dogs, or horses. Use of warfarin in veterinary species is somewhat controversial and due to unproven benefit in reducing mortality, increased expense associated with monitoring, and potential for serious effects (bleeding), many do not recommend its use.

Pharmacology/Actions

Warfarin acts indirectly as an anticoagulant (it has no direct anticoagulant effect) by interfering with the action of vitamin K₁ in the synthesis of the coagulation factors II, VII, IX, and X. Sufficient amounts of vitamin K₁ can override this effect. Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. The S enantiomer is a significantly more potent vitamin K antagonist than the R enantiomer in species studied.

Pharmacokinetics

Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. Warfarin is rapidly and completely absorbed in humans after oral administration. In cats, warfarin is also rapidly absorbed after oral administration.

After absorption, warfarin is highly bound to plasma proteins in humans, with approximately 99% of the drug bound. In cats, more than 96% of the drug is protein bound. It is reported that there are wide species variations with regard to protein binding; horses have a higher free (unbound) fraction of the drug than do rats, sheep or swine. Only free (unbound) warfarin is active. While other coumarin and indanedione anticoagulants are distributed in milk, warfarin does not enter milk in humans.

Warfarin is principally metabolized in the liver to inactive metabolites that are excreted in urine and bile (and then reabsorbed and excreted in the urine). The plasma half-life of warfarin may be several hours to several days, depending on the patient (and species?). In cats, the terminal half-life of the S enantiomer is approximately 23–28 hours and the R enantiomer approximately 11–18 hours.

Contraindications/Precautions/Warnings

Warfarin is contraindicated in patients with preexistent hemorrhagic tendencies or diseases, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, or surgery of large, open surfaces. It should not be used in patients with active bleeding from the GI, respiratory, or GU tract. Other contraindications include: aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, pregnancy, and visceral carcinomas.

Adverse Effects

The principal adverse effect of warfarin use is dose-related hemorrhage, which may manifest with clinical signs of anemia, thrombocytopenia, weakness, hematomas and ecchymoses, epistaxis, hematemesis, hematuria, melena, hematochezia, hemathrosis, hemothorax, intracranial and/or pericardial hemorrhage, and death.

Reproductive/Nursing Safety

Warfarin is embryotoxic, can cause congenital malformations and considered contraindicated during pregnancy. If anticoagulant therapy is required during pregnancy, most clinicians recommend using low-dose heparin. In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly*

outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Based on very limited published data, warfarin has not been detected in the breast milk of humans treated, but there are reports of some breast-fed infants whose mothers were treated having prolonged prothrombin times. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Acute overdosages of warfarin may result in life-threatening hemorrhage. In dogs and cats, single doses of 5–50 mg/kg have been associated with toxicity. It must be remembered that a lag time of 2–5 days may occur before signs of toxicity occur, and animals must be monitored and treated accordingly.

Cumulative toxic doses of warfarin have been reported as 1–5 mg/kg for 5–15 days in dogs and 1 mg/kg for 7 days in cats.

If overdosage is detected early, prevent absorption from the gut using standard protocols. If clinical signs are noted, they should be treated with blood products and vitamin K₁ (phytonadione). Refer to the phytonadione monograph for more information.

Drug Interactions

Drug interactions with warfarin are perhaps the most important in human medicine. The following drug interactions have either been reported or are theoretical in humans or animals receiving warfarin and may be of significance in veterinary patients:

A multitude of drugs have been documented or theorized to interact with warfarin. The following drugs or drug classes may **increase the anticoagulant response** of warfarin (not necessarily complete):

- ACETAMINOPHEN
- ALLOPURINOL
- AMIODARONE
- ANABOLIC STEROIDS
- AZITHROMYCIN
- CHLORAMPHENICOL
- CIMETIDINE
- CISAPRIDE
- CO-TRIMOXAZOLE (trimethoprim/sulfa)
- DANAZOL
- DIAZOXIDE
- ERYTHROMYCIN
- ETHACRYNIC ACID
- FLUOROQUINOLONES
- FLUOXETINE
- HEPARIN
- METRONIDAZOLE
- NSAIDS
- PENTOXIFYLLINE
- PROPYLTHIOURACIL
- QUINIDINE
- SALICYLATES
- SERTRALINE
- SULFONAMIDES
- THYROID MEDICATIONS
- ZAFIRLUKAST

The following drugs or drug classes may **decrease the anticoagulant response** of warfarin (not necessarily complete):

- BARBITURATES (phenobarbital, etc.)
- CORTICOSTEROIDS
- ESTROGENS
- GRISEOFULVIN
- MERCAPTOPYRINE
- RIFAMPIN
- SPIRONOLACTONE
- SUCRALFATE
- VITAMIN K

Should concurrent use of any of the above drugs with warfarin be necessary, enhanced monitoring is required. Refer to other references on drug interactions for more specific information.

Laboratory Considerations

- Warfarin may cause falsely decreased **theophylline** values if using the Schack and Waxler ultraviolet method of assay

Doses

■ DOGS:

For adjunctive therapy of thromboemboli:

- a) 0.22 mg/kg PO q12h; target dosage to prolong PT by 1.25–1.5 times the pretreatment value (Brooks 2000)
- b) For pulmonary thromboembolism: 0.2 mg/kg PO once daily then 0.05–0.1 mg/kg PO once daily. Adjust dosage to increase PT to 1.5–2.5 times baseline. Heparin may be stopped once appropriate warfarin dosage is established. If PT exceeds 2.5 times baseline, reduce dose. If bleeding develops, stop dose and institute blood or phytonadione therapy as appropriate. (Roudebush 1985)
- c) For prophylactic use in patients with glomerular disease and severe proteinuria: Initially, 0.22 mg/kg, PO once daily. Monitor PT and adjust dose so that PT is maintained at 1.5 times normal. (Grauer and DiBartola 2000)

■ CATS:

For adjunctive therapy of thromboembolism:

- a) For feline aortic thromboembolism: 0.06–0.1 mg/kg once daily PO. Evaluate using PT, aPTT, or preferably PIVKA (proteins induced by vitamin K antagonists) daily during initial titration (3 days), then every other day (2 times) and weekly thereafter until stable. New steady state may require one week after dosage adjustments. Long-term therapy should be monitored at least once monthly. (Pion and Kittleson 1989)
- b) For chronic management/prevention of recurrence: 0.1–0.2 mg/kg PO once daily. Adjust dosage to prolong PT to 2–2.5 times normal. Collect blood sample 8 hours after dosing. Requires 48–72 hours to achieve effective anticoagulation. Monitor PT weekly for 1 month, then at monthly intervals. Also determine hematocrit with each PT. (Harpster 1988)
- c) For thromboembolism: 0.5 mg per cat PO once daily; target dosage to prolong PT by 1.25–1.5 times the pretreatment value (Brooks 2000)
- d) For long-term thromboprophylaxis: Initially warfarin at 0.06–0.09 mg/kg per day PO. Due to unequal drug distribution, tablets should be crushed and mixed well. PT, adjusted to international normalized ratio (INR) is used to monitor therapy, but may not be applicable to cats. Overlap heparin and warfarin therapy by at least 4–5 days. Reevaluate anticoagulation status with any change in concurrent drug therapy. (Smith 2004)

- e) Initially, 0.25–0.5 mg (total dose) per cat PO once daily. Adjust dosage to prolong PT to twice normal value, or INR to be between 2–3. Overlap therapy with heparin. (Fox 2007a)

■ **HORSES: (Note: ARCI UCGFS Class 5 Drug)**

As an anticoagulant:

- a) For adjunctive treatment of laminitis: 0.0198 mg/kg PO once daily; monitor OSPT (one-step prothrombin time) until prolonged 2–4 seconds beyond baseline (Brumbaugh, Lopez et al. 1999)
- b) Initially, 0.018 mg/kg PO once daily and increase dose by 20% every day until baseline PT is doubled. Final dose rates may be from 0.012 mg/kg to 0.57 mg/kg daily. (Vrins, Carlson, and Feldman 1983)

Monitoring

Note: The frequency of monitoring is controversial, and is dependent on several factors including dose, patient's condition, concomitant problems, etc. See the Dosage section above for more information.

- While Prothrombin Times (PT) or International Normalized Ratio (INR) are most commonly used to monitor warfarin, PIVKA (proteins induced by vitamin K antagonists) has been suggested as being more sensitive. PT's are usually recommended to be 1.5–2X normal and INR's to be between 2–3.
- Platelet counts and hematocrit (PCV) should be done periodically
- Occult blood in stool and urine; other observations for bleeding
- Clinical efficacy

Client Information

- Clients must be counseled on both the importance of administering the drug as directed
- Immediately report any signs or symptoms of bleeding

Chemistry/Synonyms

A coumarin derivative, warfarin sodium occurs as a slightly bitter tasting, white, amorphous or crystalline powder. It is very soluble in water and freely soluble in alcohol. The commercially available products contain a racemic mixture of the two optical isomers.

Warfarin Sodium may also be known as: sodium warfarin, warfarinum natricum, *Coumadin*®, *Jantoven*®, or *Panwarfin*®; there are many other trade names internationally.

Storage/Stability

Warfarin sodium tablets should be stored in tight, light-resistant containers at temperatures less than 40°C, preferably at room temperature. Warfarin sodium powder for injection should be protected from light and used immediately after reconstituting.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Warfarin Sodium Tablets (scored): 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg & 10 mg; *Coumadin*® (Bristol-Myers Squibb), *Jantoven*® (Upsher-Smith), generic; (Rx)

Warfarin Sodium Powder for Injection, lyophilized: 5.4 mg (2 mg/mL when reconstituted) preservative-free in 5 mg vials; *Coumadin*® (Bristol-Myers Squibb); (Rx)

A method of suspending warfarin tablets in an oral suspension has been described (Enos 1989). To make 30 mL of a 0.25 mg/mL suspension: Crush three 2.5 mg tablets with a mortar and pestle. Add 10 mL glycerin to form a paste; then 10 mL of water; add sufficient amount of dark corn syrup (*Karo*®) to obtain a final volume of 30 mL. Warm gently; shake well and use within 30 days.

XYLAZINE HCL

(zye-la-zeen) Rompun®

ALPHA₂-ADRENERGIC AGONIST

Prescriber Highlights

- ▶ Alpha₂-adrenergic agonist used for its sedative & analgesic in a variety of species; sometimes used as an emetic in cats
- ▶ Contraindications: Animals receiving epinephrine or having active ventricular arrhythmias. Extreme caution: pre-existing cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Should generally not be used in the last trimester of pregnancy, particularly in cattle. Do not give to ruminants that are debilitated, dehydrated, or with urinary tract obstruction. Horses may kick after a stimulatory event (usually auditory); use caution. Avoid intra-arterial injection; may cause severe seizures & collapse. Caution in patients treated for intestinal impactions. Use cautiously in horses during the vasoconstrictive development phase of laminitis.
- ▶ Adverse Effects: CATS: emesis, muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, & increased urination.
- ▶ Adverse Effects: DOGS: Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, emesis, bloat from aerophagia which may require decompression.
- ▶ Adverse Effects: HORSES: Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, sweating, increased intracranial pressure, or decreased mucociliary clearance.
- ▶ Adverse Effects: CATTLE: Salivation, ruminal atony, bloating, regurgitation, hypothermia, diarrhea, bradycardia, premature parturition, & ataxia.
- ▶ Yohimbine, atipamezole, & tolazoline may be used alone or in combination to reverse effects or speed recovery times
- ▶ Dosages between species can be very different; be certain of product concentration when drawing up into syringe, especially if treating ruminants
- ▶ Drug Interactions

Uses/Indications

Xylazine is approved for use in dogs, cats, horses, deer, and elk. It is indicated in dogs, cats, and horses to produce a state of sedation with a shorter period of analgesia, and as a preanesthetic before local or general anesthesia. Because of the emetic action of xylazine in cats, it is occasionally used to induce vomiting after ingesting toxins.

Pharmacology/Actions

A potent α_2 -adrenergic agonist, xylazine is classified as a sedative/analgesic with muscle relaxant properties. Although xylazine possesses several of the same pharmacologic actions as morphine, it does not cause CNS excitation in cats, horses or cattle, but causes sedation and CNS depression. In horses, the visceral analgesia produced has been demonstrated to be superior to that produced by meperidine, butorphanol or pentazocine.

Xylazine causes skeletal muscle relaxation through central mediated pathways. Emesis is often seen in cats, and occasionally in dogs receiving xylazine. While thought to be centrally mediated, neither dopaminergic blockers (e.g., phenothiazines) nor α -blockers (yohimbine, tolazoline) block the emetic effect. Xylazine does not cause emesis in horses, cattle, sheep or goats. Xylazine depresses thermoregulatory mechanisms and either hypothermia or hyperthermia is a possibility depending on ambient air temperatures.

Effects on the cardiovascular system include an initial increase in total peripheral resistance with increased blood pressure followed by a longer period of lowered blood pressures (below baseline). A bradycardic effect can be seen with some animals developing a second-degree heart block or other arrhythmias. An overall decrease in cardiac output of up to 30% may be seen. Xylazine has been demonstrated to enhance the arrhythmogenic effects of epinephrine in dogs with or without concurrent halothane.

Xylazine's effects on respiratory function are usually clinically insignificant, but at high dosages it can cause respiratory depression with decreased tidal volumes and respiratory rates, and an overall decreased minute volume. Brachycephalic dogs and horses with upper airway disease may develop dyspnea.

Xylazine can increase blood glucose secondary to decreased serum levels of insulin; in non-diabetic animals, there appears to be little clinical significance associated with this effect.

In horses, sedatory signs include a lowering of the head with relaxed facial muscles and drooping of the lower lip. The retractor muscle is relaxed in male horses, but unlike acepromazine, no reports of permanent penile paralysis have been reported. Although, the animal may appear to be thoroughly sedated, auditory stimuli may provoke arousal with kicking and avoidance responses.

With regard to the sensitivity of species to xylazine, definite differences are seen. Ruminants are extremely sensitive to xylazine when compared with horses, dogs, or cats. Ruminants generally require approximately $1/10^{\text{th}}$ the dosage that is required for horses to exhibit the same effect. In cattle (and occasionally cats and horses), polyuria is seen following xylazine administration, probably because of decreased production of vasopressin (anti-diuretic hormone, ADH). Bradycardia and hypersalivation are also seen in cattle and diminished by pretreating with atropine. Because swine require 20–30 times the ruminant dose, it is not routinely used.

Pharmacokinetics

Absorption is rapid following IM injection, but bioavailabilities are incomplete and variable. Bioavailabilities of 40–48% in horses, 17–73% in sheep, and 52–90% in dogs have been reported after IM administration.

In horses, the onset of action following IV dosage occurs within 1–2 minutes with a maximum effect 3–10 minutes after injection.

The duration of effect is dose dependent but may last for approximately 1.5 hours. The serum half-life after a single dose of xylazine is approximately 50 minutes in the horse; recovery times generally take from 2–3 hours.

In dogs and cats, the onset of action following an IM or SC dose is approximately 10–15 minutes, and 3–5 minutes following an IV dose. The analgesic effects may persist for only 15–30 minutes, but the sedative actions may last for 1–2 hours depending on the dose given. The serum half-life of xylazine in dogs has been reported as averaging 30 minutes. Complete recovery after dosing may take 2–4 hours in dogs and cats.

Xylazine is not detected in milk of lactating dairy cattle at 5 and 21 hours post-dose, but the FDA has not approved its use in dairy cattle and no meat or milk withdrawal times have been specified.

Contraindications/Precautions/Warnings

Xylazine is contraindicated in animals receiving epinephrine or having active ventricular arrhythmias. It should be used with extreme caution in animals with preexisting cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Because it may induce premature parturition, it should generally not be used in the last trimester of pregnancy, particularly in cattle.

Be certain of product concentration when drawing up into syringe, especially if treating ruminants. Do not give to ruminants that are dehydrated, debilitated, or with urinary tract obstruction. It is not approved for any species to be consumed for food purposes.

Horses have been known to kick after a stimulatory event (usually auditory); use caution. The addition of opioids (e.g., butorphanol) may help temper this effect, but may cause increased risks for hypotension or ileus development. Avoid intra-arterial injection; may cause severe seizures and collapse. The manufacturers warn against using xylazine in conjunction with other tranquilizers. Because this drug may inhibit gastrointestinal motility, use with caution in patients treated for intestinal impactions. Use cautiously in horses during the vasoconstrictive development phase of laminitis as xylazine has been shown to reduce digital flow of blood for about 8 hours after administration.

Adverse Effects

Emesis is generally seen within 3–5 minutes after xylazine administration in cats and occasionally in dogs. To prevent aspiration, do not induce further anesthesia until this time has lapsed. Other adverse effects listed in the package insert (*Gemini*®, Butler) for dogs and cats include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and increased urination in cats.

Dogs may develop bloat from aerophagia that may require decompression. Because of gaseous distention of the stomach, xylazine's use before radiography can make test interpretation difficult.

Adverse effects listed in the package insert (*AnaSed*®, Lloyd) for horses include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and sweating (rarely profuse). Additionally, horses may develop increased intracranial pressure or decreased mucociliary clearance rates when xylazine is used.

Adverse reactions reported in cattle include: salivation, ruminal atony, bloating and regurgitation, hypothermia, diarrhea, and bradycardia. Hypersalivation and bradycardia may be alleviated by pretreating with atropine.

Large animals may become ataxic following dosing and caution should be observed.

Reproductive/Nursing Safety

Limited information was located on the safety of xylazine in pregnancy; apparently, there are no reports of teratogenicity in animals. Xylazine may induce premature parturition in cattle.

Xylazine does not appear to be excreted in detectable quantities in cows' milk.

Overdosage/Acute Toxicity

In the event of an accidental overdosage, cardiac arrhythmias, hypotension, and profound CNS and respiratory depression may occur. Seizures have also been reported after overdoses. There has been much interest in using alpha-blocking agents as antidotes or reversal agents to xylazine. Yohimbine, atipamezole, and tolazoline have been suggested for use alone and in combination to reverse the effects of xylazine or speed recovery times. Separate monographs for yohimbine and atipamezole are available with suggested doses, etc.

To treat the respiratory depressant effects of xylazine toxicity, mechanical respiratory support with respiratory stimulants (e.g., doxapram) have been recommended for use.

Drug Interactions

The manufacturers warn against using xylazine in conjunction with other tranquilizers.

■ **ACEPROMAZINE:** The combination use of acepromazine with xylazine is generally considered safe, but there is potential for additive hypotensive effects and this combination should be used cautiously in animals susceptible to hemodynamic complications.

■ **CNS DEPRESSANT AGENTS, OTHER (barbiturates, narcotics, anesthetics, phenothiazines, etc.):** May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.

■ **EPINEPHRINE:** The use of epinephrine with or without the concurrent use of halothane with xylazine may induce the development of ventricular arrhythmias.

■ **RESERPINE:** A case of a horse developing colic-like clinical signs after reserpine and xylazine has been reported. Until more is known about this potential interaction, use of these two agents together should be avoided.

Doses

■ DOGS:

- 1.1 mg/kg IV, 1.1–2.2 mg/kg IM or SC (Package Insert; Rompun®—Miles)
- 0.6 mg/kg IV, IM as a sedative (Morgan 1988)
- To treat a hypoglycemic crises (with IV dextrose): 1.1 mg/kg IM (Schall 1985)
- For epidural injection: 0.02–0.25 mg/kg; dilute with sufficient quantity of sterile saline to a volume of 0.26 mL/kg. Onset of action 20–30 minutes; 2–5 hour duration. Xylazine 0.02 mg/kg with morphine 0.1 mg/kg; dilute with sufficient quantity of sterile saline to a volume of 0.26 mL/kg. Onset of action 30–60 minutes; 10–20 hour duration. As an analgesic: 0.1–1 mg/kg IV, IM or SC. For post-operative anxiety: 0.1–0.5 mg/kg IV, IM or SC (Carroll 1999)

■ CATS:

- 1.1 mg/kg IV, 1.1–2.2 mg/kg IM or SC (Package Insert; Rompun®—Miles)
- As an emetic: 0.44 mg/kg IM (Morgan 1988), (Riviere 1985)
- As an analgesic: 0.1–1 mg/kg IV, IM or SC. For post-operative anxiety: 0.1–0.5 mg/kg IV, IM or SC (Carroll 1999)
- 0.55 mg/kg IM (Mandsager 1988)

■ RABBITS, RODENTS, SMALL MAMMALS:

- Rabbits: For minimally invasive procedures lasting less than 30–45 minutes: 5 mg/kg once SC or IM in combination with ketamine (35 mg/kg).
Mice/Rats: General anesthesia 13 mg/kg once IP in combination with ketamine (87 mg/kg).
Hamsters/Guinea pigs: General anesthesia 8–10 mg/kg once IP in combination with ketamine (200 mg/kg for hamsters and 60 mg/kg for Guinea pigs) (Huerkamp 1995)

■ FERRETS:

- As a sedative/analgesic: Xylazine: 0.5–2 mg/kg IM or SC. Usually combined with atropine (0.05 mg/kg) or glycopyrrrolate (0.01 mg/kg IM) or Butorphanol/Xylazine: Butorphanol 0.2 mg/kg plus Xylazine (2 mg/kg) IM (Finkler 1999)
- Xylazine (2 mg/kg) plus butorphanol (0.2 mg/kg) IM; Telazol (1.5 mg/kg) plus xylazine (1.5 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM)
Telazol (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)

■ BIRDS:

- As a sedative/analgesic: 1–4 mg/kg IM, provides sedation for ketamine anesthesia. Has been used at dosages of up to 10 mg/kg in small psittacines (Clyde and Paul-Murphy 2000)

■ CATTLE:

Caution: Cattle are extremely sensitive to xylazine's effects; be certain of dose and dosage form. Pretreatment with atropine can decrease bradycardia and hypersalivation.

- 0.05–0.15 mg/kg IV; 0.10–0.33 mg/kg IM. If administering IM use an 18 or 20 gauge needle at least 1.5 inches long. Intravenous route may stress cardiovascular function. (Thurmon and Benson 1986)
- 0.044–0.11 mg/kg IV; 0.22 mg/kg IM (Mandsager 1988)
- 0.1–0.3 mg/kg IM; 0.05–0.15 mg/kg IV; 0.05–0.07 mg/kg epidurally. When used IV/IM, analgesia can be very short-lived (1/2 hour). (Walz 2006b)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- 1.1 mg/kg IV; 2.2 mg/kg IM. Allow animal to rest quietly until full effect is reached. (Package Insert; Rompun®—Bayer)
- Sedative/analgesic for colic: 0.2–0.5 mg/kg IV (will provide analgesia for 20–30 minutes); or 0.6–1 mg/kg IM (effects for 1–2 hours). Evaluate heart rate prior to therapy. (Moore 1999)
- For sedation/analgesia: Xylazine 0.5–1 mg/kg IV or IM with or without butorphanol (0.02–0.03 mg/kg) (Taylor 1999)
- Prior to guaifenesin/thiobarbiturate anesthesia: 0.55 mg/kg IV; Prior to ketamine induction: 1.1 mg/kg IV; In combination with opioid/tranquilizers (all IV doses): **1)** Xylazine 0.66 mg/kg and meperidine 1.1 mg/kg; **2)** Xylazine 1.1 mg/kg and butorphanol 0.01–0.02 mg/kg; **3)** Xylazine 0.6 mg/kg; and acepromazine 0.02 mg/kg. **Note:** The manufacturers state that xylazine should not be used in conjunction with tranquilizers (Thurmon and Benson 1987)
- For field anesthesia: Sedate with xylazine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures). If adequate sedation does not occur, either: **1)** Redose xylazine: up to half the original dose, **2)** Add butorphanol (0.02–.04 mg/kg IV). Butorphanol can be given with the

original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes. **3)** Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes. **4)** Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)

■ SHEEP & GOATS:

Note: Use xylazine with extreme caution in these species.

a) 0.05–0.1 mg/kg IV; 0.1–0.22 mg/kg IM (Thurmon and Benson 1986)

b) 0.044–0.11 mg/kg IV; 0.22 mg/kg IM (Mandsager 1988)

■ EXOTICS:

a) An extensive list of suggested dosages can be found on page 359 of *Veterinary Pharmacology and Therapeutics*, 6th Ed., Booth, NH and McDonald, LE, Eds. 1988; Iowa State University Press; Ames, Iowa

Monitoring

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Hydration status if polyuria present

Client Information

- Xylazine should only be used by individuals familiar with its use

Chemistry/Synonyms

Xylazine HCl is a α_2 -adrenergic agonist structurally related to clonidine. The pH of the commercially prepared injections is approximately 5.5. Dosages and bottle concentrations are expressed in terms of the base.

Xylazine HCl may also be known as Bay-Va-1470, *Rompun*®, *AnaSed*®, *Sedazine*®, *X-Ject*®, or *Xyla-Ject*®.

Storage/Stability/Compatibility

Do not store above 30°C (86°F). Xylazine is reportedly physically **compatible** in the same syringe with several compounds, including: acepromazine, buprenorphine, butorphanol, chloral hydrate, and meperidine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Xylazine Injection: 20 mg/mL in 20 mL vials or 100 mg/mL in 50 mL vials: *AnaSed*® (Lloyd); *X-Ject*® (Butler); *Xyla-Ject*® (Phoenix); *Sedazine*® (Fort Dodge); *TranquiVed*® (Vedco); generic; (Rx); Approved for use (depending on strength and product) in dogs, cats, horses, deer, and elk.

While xylazine is not approved for use in cattle in the USA, at labeled doses in Canada it reportedly has been assigned withdrawal times of 3 days for meat and 48 hours for milk. FARAD has reportedly suggested a withdrawal of 7 days for meat and 72 hours for milk for extra-label use.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

YOHIMBINE HCL

(yo-him-been) Yobine®, Antagonil®

ALPHA₂-ADRENERGIC ANTAGONIST

Prescriber Highlights

- ▶ **Alpha₂-adrenergic antagonist used to reverse xylazine & potentially amitraz; may be used prophylactically before amitraz dips**
- ▶ **Contraindications:** Hypersensitivity to it. **Caution:** Renal disease, seizure disorders
- ▶ **Adverse Effects:** Transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, & hyperemic mucous membranes; more likely in small animals
- ▶ **Drug interactions**

Uses/Indications

Yohimbine is indicated to reverse the effects of xylazine in dogs, but it is being used clinically in several other species as well.

Yohimbine may be efficacious in reversing some of the toxic effects associated with other agents (e.g., amitraz) and can be used prophylactically before amitraz dips.

Pharmacology/Actions

Yohimbine is an α_2 -adrenergic antagonist that can antagonize the effects of xylazine. Alone, yohimbine increases heart rate, blood pressure, causes CNS stimulation and antidiuresis, and has hyperinsulinemic effects.

By blocking central α_2 -receptors, yohimbine causes sympathetic outflow (norepinephrine) to be enhanced. Peripheral α_2 -receptors are also found in the cardiovascular system, genitourinary system, GI tract, platelets, and adipose tissue.

Pharmacokinetics

The pharmacokinetics of this drug have been reported in steers, dogs, and horses (Jernigan et al. 1988). The apparent volume of distribution (steady-state) is approximately 5 L/kg in steers, 2–5 L/kg in horses, and 4.5 L/kg in dogs. The total body clearance is approximately 70 mL/min/kg in steers, 35 mL/min/kg in horses, and 30 mL/min/kg in dogs. The half-life of the drug is approximately 0.5–1 hours in steers, 0.5–1.5 hours in horses, and 1.5–2 hours in dogs.

Yohimbine is believed to penetrate the CNS quite readily and, when used to reverse the effects of xylazine, onset of action generally occurs within 3 minutes. The metabolic fate of the drug is not known.

Contraindications/Precautions/Warnings

Yohimbine is contraindicated in patients hypersensitive to it. In humans, yohimbine is contraindicated in patients with renal disease.

Yohimbine should be used cautiously in patients with seizure disorders. When used to reverse the effects xylazine, normal pain perception may result.

Adverse Effects

Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animals than in large animals.

Reproductive/Nursing Safety

Safe use of yohimbine in pregnant animals has not been established. No information on safety during lactation was located.

Overdosage/Acute Toxicity

Dogs receiving 0.55 mg/kg (5 times recommended dose) exhibited clinical signs of transient seizures and muscle tremors.

There were 51 exposures to yohimbine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 46 were dogs with 9 showing clinical signs and the remaining 5 cases were cats with 1 showing clinical signs. Common findings in dogs recorded in decreasing frequency included panting, tachycardia, agitation, hypertension and anxiety. Common findings in cats recorded in decreasing frequency included hyperactivity, tachycardia, tachypnea and tremors.

Drug Interactions

Little information is available, use with caution with **other alpha₂-adrenergic antagonists** or **other drugs that can cause CNS stimulation**.

The following drug interaction has been reported in humans receiving yohimbine and may be of significance in veterinary patients:

- **TRICYCLIC ANTIDEPRESSANTS:** In humans, yohimbine is not recommended for use with antidepressants or other mood-altering agents; hypertension has been reported with tricyclics

Doses

■ DOGS:

For xylazine reversal:

- a) 0.11 mg/kg IV slowly (Package insert; *Yobine*®—Lloyd)
- b) 0.1 mg/kg IV (Gross and Tranquilli 1989)
- c) As an antiemetic: 0.25–0.5 mg/kg q12h SC or IM (Washabau and Elie 1995)

For reversal or prevention of amitraz effects:

- a) To reverse centrally mediated bradycardia and hypotension associated with amitraz ingestion: 0.1 mg/kg IV; repeat as necessary (Manning 2000)
- b) In cases of toxicity or to prevent a dog from having an acute episode of toxicity associated with demodicosis treatment: Yohimbine at 0.11 mg/kg IV or 0.25 mg/kg IM with atipamezole (50 mcg/kg IM). (Torres 2007b)
- c) For treatment or prevention of side effects associated with amitraz dips: 0.1 mg/kg IV; may give prior to, or after bathing to prevent effects. (Hillier 2006g)

■ RABBITS, RODENTS, SMALL MAMMALS:

To reverse the effects of xylazine and to partially antagonize the effects of ketamine and acepromazine:

- a) Rabbits: 0.2 mg/kg IV as needed
- b) Mice/Rats: 0.2 mg/kg IP as needed (Huerkamp 1995)

■ BIRDS:

As a reversal agent for alpha₂-adrenergic agonists (e.g., xylazine):

- a) 0.1 mg/kg IV (Clyde and Paul-Murphy 2000)

■ CATTLE:

For xylazine reversal:

- a) 0.125 mg/kg IV (Gross and Tranquilli 1989)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

For xylazine reversal:

- a) 0.075 mg/kg IV (Gross and Tranquilli 1989)

■ LLAMAS:

For xylazine reversal:

- a) 0.25 mg/kg IV or IM (Fowler 1989)

■ DEER:

For xylazine reversal:

- a) In wild, exotic and ranched deer: 0.2–0.3 mg/kg IV (Package Insert; *Antagonil*®—Wildlife Labs)

Note: Yohimbine has also been used as a reversal agent in several exotic species. Several dosages are listed in the chapter on Stimulants by Booth in *Veterinary Pharmacology and Therapeutics*, 6th Edition. Booth, NH and McDonald, LE Eds., Iowa State University Press. Ames. 1988

Monitoring

- CNS status (arousal level, etc.)
- Cardiac rate; rhythm (if indicated), blood pressure (if indicated and practical)
- Respiratory rate

Client Information

- This agent should be used with direct professional supervision only

Chemistry/Synonyms

A Rauwolfia or indolealkylamine alkaloid, yohimbine HCl has a molecular weight of 390.9. It is chemically related to reserpine.

Yohimbine may also be known as: aphrodine hydrochloride, chlorhydrate de quebrachine, corynine hydrochloride, *Aphrodyne*®, *Dayto Himbin*®, *Pluriviron mono*®, *Prowess Plain*®, *Urobine*®, *Virigen*®, *Yobine*®, *Yocon*®, *Yocoral*®, *Yohimex*®, *Yohydrol*, *Yomax*®, or *Zumba*®.

Storage/Stability/Compatibility

Yohimbine injection should be stored at room temperature (15–30°C) and protected from light and heat.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Yohimbine Sterile Solution for Injection: 2 mg/mL in 20 mL vials; *Yobine*® (Lloyd); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

Oral 5.4 mg tablets are available, but would unlikely to be of veterinary benefit.

ZAFIRLUKAST

(zah-fur-luh-kast) Accolate®

LEUKOTRIENE-RECEPTOR ANTAGONIST

Prescriber Highlights

- ▶ Leukotriene-receptor antagonist used primarily for feline asthma; appears to have very limited efficacy
- ▶ Not for treatment of acute bronchospasm
- ▶ Well tolerated
- ▶ Dose on an empty stomach

Uses/Indications

While zafirlukast potentially could be useful in treating feline asthma, including allowing dose reductions of corticosteroid therapy, its efficacy has been disappointing to this point and most do not recommend its use. Potentially, it could be of benefit in allergy-mediated (where leukotrienes play a role) dermatologic condi-

tions, such as atopy in dogs, but evidence has been that it is not very effective.

Pharmacology/Actions

Zafirlukast selectively and competitively inhibits leukotriene receptors, specifically receptors for leukotriene D₄ and E₄ (LTD₄ and LTE₄). Additionally, it competes for receptors with some components of slow-reacting substance of anaphylaxis (SRS-A). These substances have all been implicated in the inflammatory and bronchoconstrictive aspects of bronchial asthma.

Pharmacokinetics

No specific veterinary data was located. In humans, zafirlukast is rapidly absorbed after oral administration. Food may impair the absorption of the drug, therefore, give on an empty stomach. Peak plasma levels occur about 3 hours after dosing. Zafirlukast is highly bound to plasma proteins (>99%). The drug is extensively metabolized; less than 10% of a dose is excreted in the urine, the rest in the feces. Half lives in humans average about 10 hours.

Contraindications/Precautions/Warnings

Zafirlukast is contraindicated in patients hypersensitive to it.

Zafirlukast is not indicated for, and is ineffective for treating bronchospasm associated with acute asthma attacks.

Patients with significantly decreased hepatic function may have reduced clearances (and increased plasma levels) of zafirlukast.

Adverse Effects

Veterinary experience is very limited and no adverse effects have been reported thus far. In humans, the adverse effect profile seems to be minimal; headache was noted most often, but incidence is not much different than placebo.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *B* for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Zafirlukast is excreted in milk, but it is probably safe to administer to nursing veterinary patients.

Overdosage/Acute Toxicity

In dogs, doses of up to 500 mg/kg were tolerated without mortality.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zafirlukast and may be of significance in veterinary patients:

- **ASPIRIN:** May significantly increase zafirlukast plasma levels
- **ERYTHROMYCIN:** May decrease the bioavailability of zafirlukast
- **THEOPHYLLINE:** May decrease plasma levels of zafirlukast
- **WARFARIN:** Zafirlukast may significantly increase the prothrombin time of patients taking warfarin.

Laboratory Considerations

None were noted

Doses

■ DOGS:

- a) For adjunctive treatment of atopic dermatitis: 20 mg (total dose) PO twice daily; only moderate success (Foil 2003a)

■ CATS:

- a) For adjunctive treatment of feline bronchial asthma: 1–2 mg/kg PO once to twice daily (Noone 1999)

Monitoring

- Clinical efficacy

Client Information

- Preferably give on an empty stomach.
- Give this medication even if animal appears well; do not use to treat acute asthma clinical signs.
- Because experience in veterinary medicine is minimal, report any untoward effects to the veterinarian.

Chemistry/Synonyms

A leukotriene-receptor antagonist, zafirlukast occurs as a white to pale yellow, fine amorphous powder. It is practically insoluble in water.

Zafirlukast may also be known as: ICI-204219, *Accolate*®, *Accoleit*®, *Aeronix*®, *Azimax*®, *Olmoran*®, *Resma*®, *Vanticon*®, *Zafarismal*®, *Zafirst*®, or *Zuvair*®.

Storage/Stability

Zafirlukast tablets should be stored at room temperature and protected from light and moisture. The manufacturer states that the tablets should be dispensed only in the original, unopened container.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Zafirlukast Tablets (film-coated): 10 mg & 20 mg; *Accolate*® (Astra-Zeneca); (Rx)

ZIDOVUDINE (AZT)

(zid-o-vew-den) Retrovir®

ANTIRETROVIRAL

Prescriber Highlights

- Antiretroviral agent that may be useful for adjunctive treatment of FeLV or FIV in cats
- Limited experience
- Use with caution if renal, hepatic, or bone marrow dysfunction present
- Anemia (non-regenerative) most common adverse effect in cats

Uses/Indications

In veterinary medicine, zidovudine may be useful for treating feline immunodeficiency virus (FIV) or feline leukemia virus (FeLV). While zidovudine can reduce the viral load in infected cats and improve clinical signs, it may not alter the natural course of the disease to a great extent.

Pharmacology/Actions

Zidovudine is considered an antiretroviral agent. While its exact mechanism of action is not fully understood, zidovudine is converted *in vivo* to an active metabolite (triphosphate) that interferes with viral RNA-directed DNA polymerase (reverse transcriptase). This causes a virustatic effect in retroviruses.

Zidovudine has some activity against gram-negative bacteria and can be cytotoxic as well.

Pharmacokinetics

Zidovudine is well absorbed after oral administration. In cats, oral bioavailability is approximately 95%. When administered with food, peak levels may be decreased, but total area under the curve may not be affected; peak levels occur about one hour post-dosing in cats. The drug is widely distributed, including into the CSF. It is only marginally bound to plasma proteins. Zidovudine is rapidly metabolized and excreted in the urine. Half-life in cats is about 1.5 hours.

Contraindications/Precautions/Warnings

Zidovudine is considered contraindicated in patients who have developed life threatening hypersensitivity reactions to it in the past.

Use zidovudine with caution in patients with bone marrow, renal or hepatic dysfunction. Dosage adjustment may be necessary in cats with renal or hepatic dysfunction.

Adverse Effects

In cats, reductions in RBC's, PCV and hemoglobin are the most common adverse effects reported. Anemia may be non-regenerative and is most commonly seen with the higher end of the dosage range (10–15 mg/kg). Diarrhea and weakness have also been reported. While there are many adverse effects reported in humans, granulocytopenia and GI effects appear to be the most likely to occur.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Zidovudine is excreted in milk. Clinical significance is not clear for nursing offspring.

Overdosage/Acute Toxicity

Human adults and children have survived oral overdoses of up to 50 g without permanent sequelae. Vomiting and transient hematologic effects are the most consistent adverse effects reported with overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zidovudine and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (ketoconazole, etc.):** May increase zidovudine levels
- **ATOVAQUONE:** May increase zidovudine levels
- **DOXORUBICIN:** May antagonize each other's effects; avoid use together

- **INTERFERON ALFA:** Increased risk for hematologic and hepato-toxicity
- **PROBENECID:** May increase zidovudine levels
- **MYELO-/CYTOTOXIC DRUGS** (e.g., **chloramphenicol, doxorubicin, flucytosine, vincristine, vinblastine**): Administered with zidovudine may increase the risk of hematologic toxicity
- **RIFAMPIN:** May decrease blood levels (AUC) of zidovudine

Laboratory Considerations

- None were noted.

Doses

■ CATS:

For adjunctive therapy of FeLV and FIV:

- a) For FELV: 5 mg/kg PO or SC q12h. If giving SC dilute in sterile normal saline to prevent local irritation. Check CBC weekly the first month as anemia (non-regenerative) can be seen. If values are stable; may monitor monthly. Some cats develop mild decreases in hematocrit that resolves even if treatment is continued. (Hartmann 2007)
- b) 5 mg/kg PO three times daily for five weeks, then a 4-week rest interval (Gomez, Gisbert et al. 2002)
- c) For FIV encephalopathy: 20 mg/kg PO q12h (Taylor 2003b)

Monitoring

- CBC; PCV. If PCV drops below 20% stop drug for a few days and then resume at a lower dosage (Levy 2000)
- CD4/CD8 rates, if possible
- Clinical efficacy

Client Information

- Must be considered “experimental” therapy for cats
- Must be administered as prescribed for efficacy
- Regular blood tests required

Chemistry/Synonyms

A thymidine analog, zidovudine is synthetically produced and occurs as a white to beige-colored, odorless, crystalline solid. Approximately 20 mg are soluble in one mL of water.

Zidovudine may also be known as: ZDV, azidodeoxythymidine, 3'-azido-2',3'-dideoxythymidine, azidothymidine, AZT, BW-A509U, BW-509U, compound-S, zidovudinum or *Retrovir*®; many other trade names are available.

Storage/Stability

Zidovudine oral tablets or capsules should be stored at room temperature. Protect from heat, light and moisture. The oral solution should be stored at room temperature. Zidovudine injection (for IV infusion) should be stored at room temperature and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Zidovudine Tablets: 300 mg; *Retrovir*® (GlaxoSmithKline); generic; (Rx)

Zidovudine Capsules: 100 mg; *Retrovir*® (GlaxoSmithKline); (Rx)

Zidovudine Oral Syrup/Solution: 10 mg/mL in 240 mL; generic (Aurobindo); (Rx) Zidovudine Injection: 10 mg/mL in 20 mL single-use vials; *Retrovir*® (GlaxoSmithKline); (Rx)

ZINC ACETATE ZINC SULFATE ZINC GLUCONATE

(zink)

NUTRITIONAL; TRACE ELEMENT

Prescriber Highlights

- ▶ Metal nutritional agent that may be used for zinc deficiency, to reduce copper toxicity in susceptible dog breeds (Bedlington Terriers, West Highland White Terriers) with hepatic copper toxicosis, & treat hepatic fibrosis in dogs. Has astringent & antiseptic activity topically.
- ▶ Contraindications: None; consider obtaining zinc & copper levels before treating.
- ▶ Adverse Effects: Large doses may cause GI disturbances or hematologic abnormalities (usually hemolysis), particularly if a coexistent copper deficiency exists
- ▶ Zinc overdoses (e.g., U.S. Pennies) can be serious

Uses/Indications

Zinc sulfate is used systemically as a nutritional supplement in a variety of species. Oral zinc acetate has been shown to reduce copper toxicity in susceptible dog breeds (Bedlington Terriers, West Highland White Terriers) with hepatic copper toxicosis. Zinc therapy may also be of benefit in the treatment of hepatic fibrosis in the dog. Zinc sulfate is used topically as an astringent and as a weak antiseptic both for dermatologic and ophthalmic conditions.

Pharmacology/Actions

Zinc is a necessary nutritional supplement; it is required by over 200 metalloenzymes for proper function. Enzyme systems that require zinc include alkaline phosphatase, alcohol dehydrogenase, carbonic anhydrase, and RNA polymerase. Zinc is also necessary to maintain structural integrity of cell membranes and nucleic acids. Zinc dependent physiological processes include sexual maturation and reproduction, cell growth and division, vision, night vision, wound healing, immune response, and taste acuity.

When administered orally, large doses of zinc can inhibit the absorption of copper.

Pharmacokinetics

About 20–30% of dietary zinc is absorbed, principally from the duodenum and ileum. Bioavailability is dependent upon the food in which it is present. Phytates can chelate zinc and form insoluble complexes in an alkaline pH. Zinc is stored mostly in red and white blood cells, but is also found in the muscle, skin, bone, retina, pancreas, liver, kidney, and prostate. Elimination is primarily via the feces, but some is also excreted by the kidneys and in sweat. Zinc found in feces may be reabsorbed in the colon.

Contraindications/Precautions/Warnings

Zinc supplementation should be carefully considered before administering to patients with copper deficiency.

Adverse Effects

Large doses may cause GI disturbances. Hematologic abnormalities (usually hemolysis) may occur with large doses or serum levels greater than 1000 mcg/dL, particularly if a coexistent copper deficiency exists. Zinc acetate or methionine may be less irritating to the

stomach. Mixing the contents of the capsule with a small amount of tuna or hamburger may minimize vomiting.

Reproductive/Nursing Safety

Although zinc deficiency during pregnancy has been associated with adverse perinatal outcomes, other studies report no such occurrences. In humans, since zinc deficiency is very rare, the routine use of zinc supplementation during pregnancy is not recommended. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Overdosage/Acute Toxicity

Signs associated with overdoses of zinc include hemolytic anemia, hypotension, jaundice, vomiting, and pulmonary edema. Suggestions for treatment of overdoses of oral zinc include removing the source, dilution with milk or water, and chelation therapy using edetate calcium disodium (Calcium EDTA). Refer to that monograph for possible doses and usage information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zinc and may be of significance in veterinary patients:

- **COPPER:** Large doses of zinc can inhibit copper absorption in the intestine; if this interaction is not desired, separate copper and zinc supplements by at least two hours
- **FLUOROQUINOLONES** (e.g., **enrofloxacin**, **ciprofloxacin**): Zinc salts may reduce the oral absorption of some fluoroquinolones
- **PENICILLAMINE:** May potentially inhibit zinc absorption; clinical significance is not clear
- **TETRACYCLINES:** Zinc salts may chelate oral tetracycline and reduce its absorption; separate doses by at least two hours
- **URSODIOL:** May potentially inhibit zinc absorption; clinical significance is not clear

Doses

■ DOGS:

For adjunctive treatment and prophylaxis of hepatic copper toxicosis:

- a) Initially, give a loading dose of 100 mg *elemental* zinc (zinc acetate used in this study) twice daily (separate doses by at least 8 hours) for about 3 months; then reduce dose to 50 mg (elemental zinc) twice daily. If animal vomits, give doses with a small piece of meat. Do not give within one hour of a meal. Monitoring of zinc levels every 2–3 months initially is recommended. Target zinc levels are 200–500 micrograms/dL. Do not allow levels to increase higher than 1000 micrograms/dL. May require 3–6 months of therapy before significant efficacy is noted. (Brewer, Dick et al. 1992)
- b) 5–10 mg/kg *elemental* zinc q12h; use high end of dosage range initially for 3 months, then 50 mg PO q12h for maintenance. Separate dosage from meals by 1–2 hours. Zinc acetate or methionine may be less irritating to the GI than other salts. Mixing the contents of the capsule with a small amount of tuna or hamburger may also minimize vomiting. In dogs with active copper-induced hepatitis, do not use zinc alone, but in combination with a chelator (e.g., D-penicillamine, trientine). Target zinc plasma levels >200 micrograms/dL but <400 micrograms/dL. Monitor levels every 2–3 months and adjust dosage as necessary. (Johnson 2000)
- c) 10 mg/kg *elemental* zinc (given as zinc acetate or zinc gluconate)

ate) PO twice daily. Give one hour before each meal. (Rothuizen 2003)

- d) 1.5–2.5 mg/kg zinc gluconate PO three times daily; 0.67 mg/kg zinc sulfate PO three times daily; or 100 mg (total dose) *elemental* zinc (as zinc acetate) PO twice daily. Goal is to achieve zinc plasma concentrations of 200–600 mcg/dL. After a 3–6 month loading period, dose is decreased to approximately half the original dose. Serum zinc concentrations are measured every 4–6 months. If serum level drops below 150 mcg/dL, increase dose to original level. If vomiting a problem, may mix dosage with a tablespoonful of tuna fish (in oil). (Richter 2002)

For hepatic fibrosis:

- a) 200 mg of *elemental* zinc PO once daily for a 10–25 kg dog. Keep zinc plasma levels between 200–300 mcg/dL. (Rutgers 2000)

For zinc-related dermatoses:

- a) Rapidly growing dogs: 10 mg/kg, day PO of zinc sulfate (Willemse 1992)
- b) For zinc-responsive dermatoses found in Siberian huskies, Alaskan malamutes, Great Danes, and Doberman pinschers: Zinc sulfate: 10 mg/kg PO with food either once daily or divided q12h. Alternatively, zinc methionine: 2 mg/kg PO once daily. Correct any dietary imbalances (high calcium and phytate). Lifetime therapy usually required. If vomiting occurs, lower dose or give with food.

For syndrome seen in puppies: Dietary corrections alone usually resolve the syndrome, but zinc supplementation as above, can expedite process. Some puppies require supplementation until maturity. (Kwochka 1994)

As an appetite stimulant:

- a) 1 mg/kg of *elemental* zinc PO once a day (Bartges 2003b)

■ CATS:

For adjunctive therapy of severe hepatic lipidosis:

- a) 7–10 mg/kg PO once daily, in B-Complex mixture if possible (Center 1994)

As an appetite stimulant:

- a) 1 mg/kg of *elemental* zinc PO once a day (Bartges 2003b)

Monitoring; Client Information

- See information in individual doses above

Client Information

- Although it is best to give oral zinc acetate on an empty stomach, if vomiting occurs mix with hamburger or tuna fish to decrease this side effect

Chemistry/Synonyms

Zinc acetate occurs as white crystals or granules. It has a faint acetous odor and effloresces slightly. One gram is soluble in 2.5 mL of water or 30 mL of alcohol. Zinc acetate contains 30% elemental zinc (100 mg zinc acetate = 30 mg elemental zinc).

Zinc sulfate occurs as a colorless granular powder, small needles, or transparent prisms. It is odorless but has an astringent metallic taste. 1.67 grams are soluble in one mL of water. Zinc sulfate is insoluble in alcohol and contains 23% zinc by weight (100 mg zinc sulfate = 23 mg elemental zinc).

Zinc gluconate occurs as white or practically white powder or granules. It is soluble in water; very slightly soluble in alcohol. Zinc gluconate contains 14.3% zinc (100 mg zinc gluconate = 14.3 mg elemental zinc).

Zinc acetate may also be known as: E650, or zinci acetate dihydricus.

Zinc sulfate may also be known as: zinc sulphate; zinci sulfas, zincum sulfuricum; many trade names are available.

Storage/Stability

Store zinc acetate crystals in tight containers. Unless otherwise recommended by the manufacturer, store zinc sulfate products in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as single-ingredient products for systemic use; several vitamin/mineral supplements contain zinc, however.

HUMAN-LABELED PRODUCTS:

Zinc Acetate is available from chemical supply houses. An oral orphan medication *Galzin*® is available.

Zinc Injection: 1 mg/mL (as sulfate; as 4.39 mg heptahydrate or 2.46 mg anhydrous) in 10 mL and 30 mL vials; 5 mg/mL (as 21.95 mg sulfate) in 5 mL and 10 mL vials; 1 mg/mL (as 2.09 mg chloride) in 10 mL vials; *Zinca-Pak*® (Smith and Nephew SoloPak); generic; (Rx)

Zinc Sulfate Tablets: 66 mg (15 mg zinc), 110 mg (25 mg zinc) & 200 mg (45 mg zinc); *Zinc 15*® and *Orazinc*® (Mericon); generic; (OTC)

Zinc Sulfate Capsules: 220 mg (50 mg zinc); *Orazinc*® (Mericon); *Verazinc*® (Forest); *Zinc-220*® (Alto); *Zincate*® (Paddock); generic; (Rx or OTC depending on product)

Zinc sulfate is also available in topical ophthalmic preparations.

Zolazepam – see Tiletamine HCl/Zolazepam HCl

ZONISAMIDE

(zoh-niss-a-mide) Zonegran®

ANTICONVULSANT

Prescriber Highlights

- ▶ Antiseizure medication that may be useful as an “add-on” drug for refractory epilepsy
- ▶ Half-life of 15 hours makes twice daily dosing possible
- ▶ Adverse effect profile not fully elucidated for dogs; sedation, ataxia, & inappetence have been reported
- ▶ Known teratogen in dogs
- ▶ Contraindicated in patients hypersensitive to sulfonamides
- ▶ Expense may be an issue

Uses/Indications

Zonisamide may be useful as an “add-on” drug for refractory epilepsy in dogs.

Pharmacology/Actions

The exact mechanism of action for zonisamide is not known. It may produce its antiseizure activity by blocking sodium channels and reducing transient inward currents, thereby stabilizing neuronal membranes and suppressing neuronal hypersynchronization. It does not appear to potentiate GABA. Zonisamide has weak carbonic anhydrase inhibitory activity.

Pharmacokinetics

In dogs, zonisamide is well absorbed after oral administration and has low protein binding. The elimination half-life in dogs is about 15 hours. Most of the drug is excreted via the kidneys into the urine, but about 20% is metabolized, primarily in the liver.

Contraindications/Precautions/Warnings

Zonisamide is contraindicated in patients hypersensitive to it or to any of the sulfonamide drugs.

Adverse Effects

Because there has been limited use of this drug in veterinary patients the adverse effect profile is not fully known. Adverse effects that have been reported in dogs include sedation, ataxia, and inappetence.

In humans, the most common adverse effects associated with zonisamide include anorexia, nausea, dizziness, somnolence, agitation and headache. Rarely, serious dermatologic reactions (Stevens-Johnson syndrome, TEN), blood dyscrasias, oligohidrosis, and hyperthermia have been reported in humans.

Reproductive/Nursing Safety

When zonisamide was administered to pregnant dogs at 10 or 30 mg/kg/day (approximate therapeutic dosages in dogs), ventricular septal defects, cardiomegaly and various valvular and arterial anomalies were seen at the higher dose. A plasma level of 25 mcg/mL was the threshold level for malformation. If this drug is to be used in pregnant dogs, the owner must accept the significant risks associated with its use.

It is not known if zonisamide enters maternal milk; use with caution in nursing animals.

Overdosage/Acute Toxicity

The LD₅₀ of zonisamide in dogs is reportedly 1 g/kg. In human overdoses, effects reported include coma, bradycardia, hypotension, and respiratory depression. Treatment recommendations include GI evacuation, if ingestion was recent, and supportive therapy. Because of the drug's long half-life, support may be required for several days.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zonisamide and may be of significance in veterinary patients:

- **PHENOBARBITAL:** While there is concern that drugs that induce liver enzymes (*e.g.*, phenobarbital) can increase the metabolism and clearance of zonisamide, it is not known if this significantly alters the pharmacokinetics of zonisamide in dogs. Since most dogs subsequently receiving zonisamide have been on phenobarbital chronically and only about 20% of a dose of drug is biotransformed, it may not be significant.

Laboratory Considerations

- No specific laboratory interactions or considerations were noted
- While plasma concentrations of zonisamide are not routinely monitored in human patients, in dogs, the therapeutic range has been suggested to be from 10–40 mcg/mL

Doses

■ DOGS:

- a) For refractory epilepsy: 10 mg/kg q12h PO twice daily (Dewey, Guiliano et al. 2003)
- b) As a secondary anticonvulsant for refractory epilepsy: 8–12 mg/kg PO q8h (Inzana 2004)
- c) 8–12 mg/kg PO q8–12h (Knipe 2006a)
- d) Initial dose: 5–10 mg/kg PO q12h; gradual adaptation in dosing is recommended. Reduce phenobarbital doses by 25% at the time of starting zonisamide. (Podell 2006a)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Clients must understand that the clinical use of this agent is relatively “investigational” in veterinary patients, that it must be dosed often in dogs and, also, the potential costs
- Caution clients not to stop therapy abruptly or “rebound” seizures may occur
- Have clients maintain a seizure diary to help determine efficacy

Chemistry/Synonyms

A sulfonamide unrelated to other antiseizure drugs, zonisamide occurs as a white powder with a pKa of 10.2. It is moderately soluble in water (0.8 mg/mL).

Zonisamide may also be known as: AD-810, CI-912, PD-110843, *Excegran*®, or *Zonegran*®.

Storage/Stability

Zonisamide capsules should be stored at 25°C (76°F); excursions permitted to 15–30°C (59–86°F). Store in a dry place and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Zonisamide Capsules: 25 mg, 50 mg & 100 mg; *Zonegran*® (Eisai); generic; (Rx)

Appendix

Ophthalmic Products, Topical

The following section lists the majority of veterinary-labeled ophthalmic topical products and some of the more commonly used human-labeled products in veterinary medicine; written by Gigi Davidson, Dip ICVP with input from Michael Davidson, DVM, Dip ACVO. Drugs are listed by therapeutic class.

For additional information, an excellent review on veterinary ophthalmic pharmacology and therapeutics can be found in both of the following textbooks: *Slatter's Fundamentals of Veterinary Ophthalmology*, 4th. Edition. David Maggs, Paul Miller, Ron Ofri, Editors, Elsevier, 2007, 496 pages, and *Veterinary Ophthalmology*,

4th Edition; Kirk N Gelatt, Editor; Lippincott Williams & Wilkins, Media, Pennsylvania, 2007. 1568 pp.

Routes of Administration for Ophthalmic Drugs

The route of administration selected to delivery therapy for an ocular condition is critical to successful therapy. The following table lists advantages and disadvantages of each route of administration for ocular medications.

Route	Tissues Reached	Dosage Forms	Advantages	Disadvantages	Comments
Topical	<i>Conjunctiva; Cornea; Anterior uvea; Lids</i>	Solutions Suspensions	Easier administration for small animals; minimal interference with vision; lower incidence of contact dermatitis; less toxic to interior of eye if penetrating wound	More difficult to administer to horses; less contact time with eye; requires more frequent application than ointment; diluted by tearing; generally more expensive than ointment; more systemic absorption	Doses >1 drop rarely indicated (maximum tear capacity is 10 – 20µl, volume of a drop is 25 – 50µl); allow 5 minutes between drops; instill in order of least viscous to most; instill in order of aqueous prior to oil base
		Ointments	Longer contact time; less frequent administration; protect cornea from drying; not diluted by tearing; generally less expensive than solutions/suspensions	Contribute to volume of ocular discharge; temporary blurring of vision; more difficult for client administration; more contact dermatitis; should not be applied to penetrating corneal wounds as oils will cause a granulomatous uveitis; difficult to determine exact dose; metal tubes often fatigue and split before all medication is used	Owners should be counseled to avoid contact of application tube with eye; observe patient for short while after application due to temporarily blurred vision
Subconjunctival injection	<i>Cornea; Anterior uvea</i>	Sterile solutions and suspensions	Longer duration of action; higher anterior chamber concentrations than topical;	Limited number of injections can be performed; may create scar tissue; cannot be removed once applied; temporary pain; drug vehicle residues	Indicated for poorly compliant owners, uncooperative patients; indicated for drugs with poor corneal penetration
Retrobulbar injection	<i>Posterior segment; Optic nerve</i>	Sterile solutions and suspensions			Primarily used for local anesthetic prior to enucleation of the eye
Intracameral injection	<i>Anterior chamber; Posterior segment</i>	Sterile solutions and suspensions	Allows very high drug concentrations for intraocular infections	Risk of hemorrhage, retinal detachment, cataract formation, and retinal degeneration	Rarely used except for severe intraocular infections or for administration of tPA to dissolve fibrin clots in the anterior chamber
Systemic Drugs	<i>Lids; Posterior segment; Optic nerve; Anterior uvea (occasionally)</i>	Oral Intramuscular Subcutaneous Intravenous	Allows drug penetration to areas where topical therapy will not reach	Systemic toxicity; Does not reach cornea; expense directly proportional to body weight in most cases	See monographs for use of systemic agents.

Diagnostic Agents

Note: A logical sequence of diagnostic tests must be used to perform ocular examination based on the special needs of each diagnostic agent and test. For example, evaluation of the tear film is performed with the Schirmer Tear Test and must be done before the eye is manipulated or any drug agents are instilled in order to provide a true picture of tear production. Likewise, cultures of the external ocular structures must be done prior to extensive cleaning or administration of any drugs that may alter bacterial culture. The use of mydriatics is essential to examination of the interior elements of the eye, but must not be given prior to measuring intraocular pressure as these agents will likely affect aqueous humor outflow. Intraocular pressure determination requires topical anesthetic, but must quickly be recorded prior to excessive manipulation of the eye or before the patient becomes anxious and uncooperative.

FLUORESCIN SODIUM

(flure-e-seen)

Indications/Pharmacology

Fluorescein sodium is a yellow water-soluble dye that fluoresces under a Wood's Lamp, but is plainly visible after binding to corneal stroma through an ophthalmic examination light source. It is used most commonly to delineate full thickness loss of corneal epithelium indicating the presence of a corneal ulceration. In this instance it will stain the corneal stroma. The epithelium is not stained because its outer lipid cell membrane repels the stain. Descemet's membrane will not stain with fluorescein stain and this is used to indicate descemetocoele formation, an ocular emergency.

Fluorescein stain is applied to the precorneal tear film in dogs and cats and the break-up of this stain with time, as observed through a slit lamp biomicroscope using a cobalt blue light source, is used to determine the tear film break-up time (normal 19 seconds), an indicator of tear film quality.

Fluorescein stain is applied to the tear film of dogs to determine patency of the nasolacrimal outflow system. The normal wait time is 2 – 5 minutes in dogs and up to 10 minutes in cats. A positive test indicates patency of the system. A negative test is not indicative of disease as the test is negative in a large percentage of normal animals. Fluorescein stain, then, can be added to irrigating solution to flush the nasolacrimal system, making detecting the irrigation solution at the nose more obvious during flushing of the system.

Suggested Dosages/Precautions/Adverse Effects

Fluorescein stain is applied by dropping a drop of irrigating solution onto the sterile strip and then allowing the drop to fall on the eye. The strip should not contact the cornea or it will cause false positive stain retention at the site of contact with the epithelial cells. Fluorescein impregnated paper strips are preferred to fluorescein solution to insure sterility. After a few seconds, the excess fluorescein is irrigated from the eye, staining areas of full thickness epithelial loss.

For procedures requiring topical anesthesia as well as a disclosing agent, benoxinate is added to fluorescein solutions in a ratio of 0.25% fluorescein to 0.4% benoxinate. These solutions are useful for removal of foreign bodies or sutures, but are not commonly used in veterinary medicine.

Conjunctival or corneal epithelial cells for fluorescent antibody testing should be collected prior to application of fluorescein stain, which can cause a false positive test for several days after application of the stain.

Fluorescein may rarely cause hypersensitivity reactions. Temporary staining of fur and skin may result. Do not use during intraocular surgery.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sterile strips of paper impregnated with fluorescein sodium are the most commonly used form in veterinary medicine. Solutions (2%) of fluorescein are available, however they are not popular following one study indicating that *Pseudomonas* is readily grown in such solutions. Injectable products are also available (for ophthalmic angiography), but are not routinely used in veterinary medicine.

Fluorescein Sodium Strips: 0.6 mg, *Ful-Glo*® (Barnes Hind); 1 mg, *Fluor-I-Strip*®-A.T. (W-A); 9 mg, *Fluor-I-Strip*® (W-A); (all Rx); 1 mg *Bio-Glo*®, 100 ct or 300 ct (Wilson Ophthalmic,) *AK Flor 10% Injection* (Akorn) 5 mL ampules

Fluorescein Sodium:Benoxinate: *Fluress*® (Akorn) 0.25:0.4% Drops in 5 mL, *Fluorox*® (Hub) 0.25:0.4% Drops in 5 mL, *Flurate*® (Bausch and Lomb) 0.25:0.4% Drops in 5 mL.

LISSAMINE GREEN

(lis-ah-meen)

Indications/Pharmacology

Lissamine green is used for diagnosis of corneal damage and to quantify tear production. These strips work by staining the cornea blue upon instillation, resulting in a "speckling" of the cornea. This speckling marks any corneal ulcerations as well as dry patches from any muco-deficient or damaged corneal cells. A white or blue light may be used on the slit lamp during detection. Lissamine green possesses a therapeutic advantage in that it does not sting the eye like Rose Bengal; however, as interpretation of lissamine green results requires broader experience than that of Rose Bengal and fluorescein, fluorescein staining is considered to be a more reliable indicator of corneal damage.

Suggested Dosages/Precautions/Adverse Effects

Lissamine Green impregnated strips are placed in the conjunctival sac and staining is scored based on 6 areas of staining.

Dosage Forms/Regulatory Status

VETERINARY-APPROVED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lissamine Green Ophthalmic Strips (Imperial Chemical Industries—available through distributors such as Wilson Ophthalmic) 1.5 mg, 100 individually wrapped strips per box.

PHENOL RED THREAD

(fee-nol)

Indications/Pharmacology

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantitatively with either the Schirmer Tear Test or the Phenol Red Thread Test. The Phenol Red Thread (PRT) test is a new, fast and equally accurate method to test tear production as compared to the Schirmer Tear Test. The PRT test has a 75mm long yellow-colored thread that is impregnated with phenol red, a pH sensitive indicator.

Suggested Dosages/Precautions/Adverse Effects

The 3mm indentation at the end of the thread is inserted into the inferior conjunctival sac for 15 seconds. As tears travel up the thread, the alkaline pH of the tears turns the thread red. The PRT requires only 15 seconds for diagnostic results as opposed to 1 minute for the Schirmer Tear Test in dogs. Normal tear production via PRT in cats at 15 seconds is 18.4 to 27.7 mm/15 seconds and, in dogs, 29.7 to 38.6 mm/15 seconds.

Dosage Forms/Regulatory Status

VETERINARY-APPROVED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Phenol Red Thread Test: *Zone-QuickDiagnostic Threads*®, 100 per box, (Menicon—available through distributors such as Wilson Ophthalmic)

PROPARACAINE HCL

(proe-par-a-kane)

Indications/Pharmacology

Proparacaine is a rapid acting topical anesthetic useful for a variety of ophthalmic procedures including tonometry (intraocular pressure measurement), relief of corneal pain to facilitate examination, biopsy/sample collection, and to distinguish between corneal and uveal pain. Proparacaine primarily anesthetizes the cornea; with limited penetration into conjunctiva. Anesthesia is of short duration (5 – 10 minutes).

Suggested Doses/Precautions/Adverse Effects

Usual dose is 1–2 drops prior to examination or procedure. For prolonged procedures only requiring local anesthesia; may repeat 1 drop doses every 5–10 minutes for 5–7 doses.

Topical anesthetics should not be used to treat painful eye disease. Prolonged use may retard wound healing and cause corneal epithelial ulcers. Because the blink reflex may be suppressed, the eye should be protected from external injury during use. Repeated use may lead to rapid development of tolerance. Local allergic-type reactions have been rarely reported in humans.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Proparacaine HCl Solution: 0.5% in 15 mL bottles; *Ophthaine*® (Solvay); (Rx). Protect from light. Refrigerate.

HUMAN-LABELED PRODUCTS:

Proparacaine HCl Solution: 0.5% in 2 & 15 mL bottles; *Ophthetic*® (Allergan), *Alcaine*® (Alcon), *Ophthaine*® (Squibb), *AK-Taine*® (Akorn), Generic; (Rx). Protect from light. Some products should be refrigerated; check label.

ROSE BENGAL

(rose ben-gall)

Indications/Pharmacology

Rose bengal is a vital stain and stains dead epithelial cells and mucus. Full thickness loss of the corneal epithelium is not necessary (only dead cells need be present) to obtain rose bengal stain uptake. It does not stain epithelial defects and does not pass into intercellular spaces.

Rose bengal stain is most commonly employed in the detection of the presence of viral keratitis in the cat. Because feline herpes virus tends to infect one cell, moving then to an adjacent cell (causing the so called dendritic tracts in the cornea) without full thickness loss of corneal epithelium initially, rose bengal is an ideal diagnostic agent for this infection. Rose Bengal can also be used to detect damaged corneal epithelium on the dorsal cornea in early cases of keratoconjunctivitis sicca. Rose bengal stain is virucidal although no information is available relative to its use as a therapeutic agent.

Suggested Dosages/Precautions/Adverse Effects

Rose Bengal is applied as a solution (1–2 drops in conjunctival sac before examination) or from an impregnated strip (saturate tip of strip with sterile irrigating solution; touch bulbar conjunctiva or lower fornix with moistened strip; cause patient to blink several times to distribute the stain).

Rose bengal is apparently toxic to the cornea and conjunctiva and should be thoroughly flushed from the eye after use to prevent irritation. Hypersensitivity reactions are possible. May stain clothing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Rose Bengal Solution: 1% in 5 mL dropper bottles (Spectrum); (Rx)

Rose Bengal Strips: 1.3 mg per strip; *Rosets*® (Akorn), Generic (Barnes-Hind); (Rx)

SCHIRMER TEAR TEST

(shir-mer)

Indications/Dosages/Precautions

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantita-

tively by the Schirmer Tear Test or the Phenol Red Thread Test. The Schirmer Tear Test measures the aqueous aspect of tears and is the most commonly used test for measuring tear production.

Suggested Dosages/Precautions/Adverse Effects

Because of the risk of false readings, the following should be avoided prior to conducting a Schirmer Tear Test: excessive manipulation of the eyelids, topical anesthesia, and topical or systemic drugs (e.g., tranquilizers and atropine). The round end of the test paper is bent while still in the envelope and positioned to avoid contamination. The bent end should be positioned in the lacrimal lake at the junction of the lateral and middle thirds of the lower eyelid. Most animals will close the eye during the test but this does not affect results. The Schirmer Tear Test should be left in position for one minute as results are not linear and cannot be extrapolated from shorter test times. Schirmer tear test values are as follows for the following species: Dogs: 21.9 +/- 4.0 mm wetting per minute, Rabbits: 5.3 +/- 2.9 mm wetting per minute, Cats: 20.2 +/- 4.5 mm wetting per minute.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Schirmer Tear Test®: 300 individually wrapped strips, (Schering Plough Animal Health)

HUMAN-LABELED PRODUCTS:

Clemente Clarke® *Schirmer Tear Test Strips*: 50 pair/box, *Schirmer Tear Test Strips*® (Alcon)

TETRACAIN

(tet-ra-kane)

Indications/Pharmacology

Tetracaine is more irritating than proparacaine but is sometimes used in veterinary medicine. It is indicated to produce local anesthesia of short duration for ophthalmic procedures including measurement of intraocular pressure (tonometry), removal of foreign bodies and sutures, and conjunctival and corneal scraping in diagnosis and gonioscopy. Tetracaine is also indicated to produce local anesthesia prior to surgical procedures in humans such as cataract extraction and pterygium excision, usually as an adjunct to locally injected anesthetics. Ophthalmic solutions used for intraocular procedures should be preservative-free. Preservatives may cause damage to the corneal epithelium if a significant quantity of solution enters the eye through the incision.

Suggested Dosages/Precautions/Adverse Effects

Usual dose is 1–2 drops prior to examination or procedure. The onset of action is about 15 seconds. The duration of action usually extends with repeated applications.

Topical anesthetics should not be used to treat painful eye disease. Prolonged use may retard wound healing and cause corneal epithelial ulcers. Because the blink reflex may be suppressed, the eye should be protected from external injury during use. Repeated use may lead to rapid development of tolerance. Local allergic-type reactions have been rarely reported in humans.

Tetracaine Injection 10 mg/mL; 2 mL ampules; *Pontocaine*® (Hospira); (Rx)

Glaucoma, Topical Agents

Note: It is important to review the basic pathophysiology of glaucoma in order to understand drug therapy of this disease. Aqueous humor production results from ciliary body secretion and ultrafiltration of plasma. Carbonic anhydrase is a vital enzyme in the production of aqueous humor. Outflow of aqueous humor flows from the posterior chamber into the anterior chamber and exits at the iridocorneal angle, or exits through the iris, ciliary body, choroids, and sclera. The balance of generation and outflow of aqueous humor maintains the intraocular pressure at between 15 and 25 mmHg. By definition, glaucoma is an increase in intraocular pressure with resulting visual deficits. Delayed, inadequate or inappropriate therapy can result in severe pain and irreversible blindness as well as a cosmetically unappealing eye. Generally, once acute congestive primary glaucoma (generally breed-related and hereditary) is noted in one eye in the dog, it is treated as an emergency using a topical prostaglandin such as latanoprost. Surgery may be considered for lasting control of intraocular pressure. The following topical drugs are used “in general” as a preventative measure to prevent the occurrence of primary glaucoma in the unaffected eye in canine patients. Topical ocular antihypertensive medications are sometimes employed for pressure control with secondary glaucomas also. Because primary glaucoma in dogs is a progressive disorder, many patients are initially treated with single agents but combinations of drugs are often ultimately necessary to maintain pressure control.

Primary glaucoma in the feline species is increasingly being recognized in several forms. Although breed-related glaucoma in Siamese and Persian cat breeds has been noted, many veterinary ophthalmologists feel that domestic short-haired cats are most likely affected. One form involving misdirected flow of aqueous humor into the vitreous, secondarily resulting in a forward displacement of the lens-iris diaphragm, has been described in the literature. The forward displacement of the iris has resulted in an average intraocular pressure of 30 mm Hg in most patients. Topical medications have been successful in preventing progressive vision loss in most of these cats. Other forms of feline glaucomas which are presumably genetic are being noted sporadically in clinical practice and most of these cases, in complete contrast with primary glaucoma in the canine, are managed successfully with medications. Pharmacologic agents utilized for medical treatment of glaucoma are noted below categorized by therapeutic class but not by therapeutic priority.

Parasympathomimetics (Miotics)

PILOCARPINE HCL

(pye-loe-kar-peen)

Indications/Pharmacology

Pilocarpine is a miotic agent that is rarely used in the treatment of canine primary glaucoma. Pilocarpine causes the ciliary body muscle to constrict placing posteriorly directed tension on the base of the iris to mechanically pull open the iridocorneal angle structures. By causing miosis, it may prevent closure of the iridocorneal angle by preventing excess iris tissue from peripherally compromising the outflow of aqueous humor. Pilocarpine has also been used for diagnostic localization of parasympathetic denervation of the iris sphincter caused by lesions or trauma to Cranial Nerve III.

The popularity of treatment of KCS with ophthalmic cyclosporine and tacrolimus has been associated with a decline in the use of pilocarpine for this disease; however, pilocarpine is still used orally as the primary treatment of neurogenic keratoconjunctivitis sicca in dogs as this condition does not respond to cyclosporine or tacrolimus.

Suggested Dosages/Precautions/Adverse Effects

One drop in affected eye(s) 3 times daily. Usually 1% or 2% is most commonly used in veterinary medicine. Pilocarpine can cause local irritation initially. In humans, this irritation reportedly diminishes after 3 days of therapy. It may also cause inflammation of the uveal tract, especially with repeated applications and can cause hyphema. Pilocarpine should not be used in secondary glaucoma cases. With repeated use, pilocarpine may cause systemic effects (vomiting, diarrhea, and increased salivation). For diagnosis of parasympathetic denervation or other conditions caused by cranial nerve III lesions, a 0.2% solution of pilocarpine is applied topically. For neurogenic keratoconjunctivitis sicca, a 2% solution of pilocarpine is given orally (in food) at a dose of 2 drops per 20 lbs of body weight twice daily. The dose is increased weekly until signs of toxicity or until control of symptoms is achieved.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pilocarpine HCl Ophthalmic Solution: 0.25%, 0.5%, 1%, 2%, 3%, 4%, and 6% (in addition there are 8% and 10% solutions and a 4% gel is available from Alcon) in 15 mL and 30 mL containers; *Isopto Carpine*® (Alcon); *Ocu-Carpine*® (Iomed); *Piloptic*® (Optopics); *Pilostat*® (Bausch and Lomb), generic; (Rx)

See also the epinephrine monograph for information on epinephrine/pilocarpine fixed dose combination products.

DEMECARIUM BROMIDE

(deh-meh-kar-ee-um)

Indications/Pharmacology

Demecarium is a potent carbamate inhibitor that may reduce intraocular pressures for up to 48 hours in canines. Demecarium reversibly inhibits anticholinesterase thereby causing miosis. Demecarium is generally used in preventive management of the contralateral eye in canine patients after the diagnosis of an acute congestive crisis of primary glaucoma in the other eye. It is not used in secondary glaucoma. Demecarium has the advantage of once or twice daily dosing.

Suggested Dosages/Precautions/Adverse Effects

One drop once or twice daily. Demecarium is contraindicated during pregnancy. Because of additive effects, demecarium should be used with caution with other cholinesterase inhibitors (e.g., carbamate/organophosphate antiparasiticide), or succinylcholine. Demecarium may cause local inflammation (alleviated by addition of topical corticosteroids) and systemic adverse effects (vomiting, diarrhea, increased salivation, cardiac effects) are possible, particularly with high dosages or in very small dogs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Formerly available as: Demecarium 0.125% or 0.25% in 5 mL drop-per bottles; *Humorsol*® (Merck); (Rx). Do not freeze and protect from heat. Demecarium must be obtained from a compounding pharmacy.

ECHOTHIOPHATE IODIDE

(ek-oh-thye-oh-fate eye-oh-dide)

Indications/Pharmacology

Echothiophate iodide for ophthalmic solution is a long-acting cholinesterase inhibitor for topical use that enhances the effect of endogenously liberated acetylcholine in iris, ciliary muscle, and other parasympathetically innervated structures of the eye. It thereby causes miosis, increase in facility of outflow of aqueous humor, fall in intraocular pressure, and potentiation of accommodation. Echothiophate iodide for ophthalmic solution will depress both plasma and erythrocyte cholinesterase levels in most patients after a few weeks of eye drop therapy.

Suggested Doses/Precautions/Adverse Effects

One drop twice daily. Echothiophate is contraindicated in the presence of active uveal inflammation, and in most cases of angle-closure glaucoma, due to the possibility of increasing angle block. Temporary or permanent discontinuation of the drug may be required if cardiac irregularities, urinary incontinence, diarrhea, muscle weakness or respiratory difficulties occur. Echothiophate should be avoided in patients with asthma, gastric ulcers, bradycardia, hypotension, epilepsy or other disorders that may respond adversely to vagotonic effects. Carbamate and organophosphate pesticides should not be used on patients receiving echothiophate.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Echothiophate Iodide Solution: 0.125% in 5 mL; *Phospholine Iodide*® (Wyeth); (Rx). Stored under refrigeration. Once reconstituted, may be stored at room temperature for up to 4 weeks.

Sympathomimetics**APRACLONIDINE**

(a-pra-kloe-ni-deen)

Indications/Pharmacology

Apraclonidine is an alpha₂ adrenergic agonist used to reduce aqueous humor secretion. Apraclonidine is a relatively selective, alpha-adrenergic agonist and does not have significant membrane stabilizing (local anesthetic) activity. The onset of action is within 3–5 hours of a single dose. It apparently is less effective than brimonidine in dogs and is very potent, causing vomiting and diarrhea in cats and dogs. Apraclonidine will reduce aqueous production but must be combined with other agents for adequate control. Neither the beta-blockers nor alpha-agonists are as effective as the carbonic anhydrase inhibitors in decreasing aqueous production.

Suggested Dosage/Precautions/Adverse Effects

1% solution applied as 1 drop 2–3 times daily. Apraclonidine should be used with caution in the face of hepatic and renal function impairment (since a structurally related medication, clonidine, is partly metabolized in the liver and undergoes a significant increase in half life in humans with renal impairment). Ironically, in humans the 0.5% concentration is more likely to cause cardiovascular adverse effects than the 1% solution. In humans the following side effects have been noted: For 0.5% ophthalmic apraclonidine: Allergic reaction, abnormal coordination, arrhythmia, asthma, blepharitis, blepharoconjunctivitis, conjunctivitis, blurred vision or change in vision, chest pain, contact dermatitis, corneal erosion, corneal infiltrate, foreign body sensation, keratitis, keratopathy, depression, dizziness, dyspnea, edema of eye, eyelid, or conjunctiva, eye discharge, facial edema, lid retraction, paresthesia, or peripheral edema. For 1% ophthalmic apraclonidine: Allergic reaction, arrhythmia, or ocular inflammation or injection.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Apraclonidine 0.5% Solution: 5 mL & 10 mL; 1% *Iopidine*® (Alcon); (Rx). Supplied as follows: 0.1 mL in plastic ophthalmic dispensers, packaged two per pouch. These dispensers are enclosed in a foil overwrap as an added barrier to evaporation.

BRIMONIDINE

(bri-moe-ni-deen)

Indications/Pharmacology

Brimonidine is an alpha-adrenergic receptor agonist. It has a peak ocular hypotensive effect occurring at two hours post-dosing. Fluorophotometric studies in animals and humans suggest that

brimonidine tartrate has a dual mechanism of action by reducing aqueous humor production and by increasing uveoscleral outflow. After ocular administration of either a 0.1% or 0.2% solution, plasma concentrations peaked within 0.5 to 2.5 hours and declined with a systemic half-life of approximately 2 hours. In humans, systemic metabolism of brimonidine is extensive. It is metabolized primarily by the liver. Urinary excretion is the major route of elimination of the drug and its metabolites. Approximately 87% of an orally-administered radioactive dose was eliminated within 120 hours, with 74% found in the urine.

Suggested Dosages/Precautions/Adverse Effects

The usual dosage is 1 drop in the affected eye twice daily. Adverse events in humans include: allergic conjunctivitis, conjunctival hyperemia, and eye pruritus, burning sensation, conjunctival folliculosis, hypertension, oral dryness, and visual disturbance. Brimonidine appears to be better tolerated in animals than apraclonidine.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Brimonidine 0.15% solution: 5 mL, 10 mL, & 15 mL; *Alphagan P*® (Allergan); various generics as 0.1% and 0.2% solutions; (Rx)

Brimonidine 0.2%/Timolol maleate: 0.5% in 5 mL & 10 mL; *Combigan*® (Allergan); (Rx)

Beta-Adrenergic Antagonists**BETAXOLOL**

(be-tax-oh-lol)

Indications/Pharmacology

Betaxolol HCl is a specific Beta₁ adrenergic blocking agent which reduces aqueous humor production by decreasing cyclic-AMP synthesis in the ciliary body. This drug is a suitable substitute for timolol and because of its specific Beta₁ activity, might be a first choice Beta blocking agent for patients with concurrent respiratory disease. Either levobunolol HCl or betaxolol HCl would be the first choice Beta blocking agent in a feline patient with glaucoma and asthma, although a topical carbonic anhydrates inhibitor should be considered before a Beta blocking agent in this situation. Betaxolol and the other Beta blockers should be used with caution in patients with cardiac disease.

Suggested Dosages/Precautions/Adverse Effects

Like timolol maleate, betaxolol HCl is supplied in a 0.50% and 0.25% solution. Because in animal patients, minimal pressure reduction is noted with concentrations below 0.5% with timolol maleate, many veterinary ophthalmologists only consider use of the 0.5% betaxolol HCl product. One drop of the 0.5% betaxolol HCl solution is instilled twice daily alone or in combination with other glaucoma medications. While problems have rarely been noted in veterinary medicine, ophthalmic beta blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure, although the selective B₁ blocking properties of this particular drug would tend to minimize these risks for patients with pulmonary disease.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Betaxolol HCl 0.5% and 0.25% Solution: 2.5, 5, 10, & 15 mL bottles; *Betoptic®* & *Betoptic - S®* (Alcon); (Rx)**CARTEOLOL**

(kar-tee-oh-lole)

Indications/Pharmacology

Carteolol HCl is a nonspecific beta adrenergic blocking agent and it reduces aqueous humor production by decreasing cyclic-AMP synthesis in the ciliary body. Carteolol is a suitable substitute for timolol maleate or any of the other beta blocking agents although it is rarely used in veterinary medicine. In humans, similar IOP reducing effects have been shown for all members of this class. Substitutes are necessary when one particular product induces topical irritation upon application. As noted above, beta blocking agents seem to be particularly useful in the management of primary glaucoma in cats.

Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 1% solution. While problems have rarely been noted in veterinary medicine, ophthalmic beta blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Carteolol HCl 1% Solution: 5, 10 & 15 mL bottles; *Ocupress®* (Otsuka America); (Rx)**LEVOBUNOLOL HCL**

(lee-voe-byoo-noe-lole)

Indications/Pharmacology

Levobunolol HCl is a beta1- and beta2-blocking agent similar to timolol and metipranolol above but without the potential for myocardial depression or airway constriction noted rarely in veterinary medicine and occasionally in human patients. Levobunolol is used in humans with glaucoma responsive to beta adrenergic blocking agents but who suffer cardiac and respiratory side effects associated with timolol. Levobunolol HCl and then carteolol HCl would be suitable Beta blocking agents for feline patients with glaucoma and asthma, although carbonic anhydrase inhibitors should be used in such cases prior to adding a Beta blocking agent.

Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.5% concentration. Miosis may develop in veterinary patients after application of topical beta blocking antiglaucoma medications.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Levobunolol HCl 0.25% or 0.5% solution: 5, 10, & 15 mL. *Betagan®* (Allergan); (Rx)**METIPRANOLOL**

(meti-pran-oh-lol)

Indications/Pharmacology

Metipranolol HCl can be used as a substitute for timolol maleate (see above). Metipranolol is a nonselective beta blocking agent and reduces intraocular pressure minimally in animals by decreasing cyclic-AMP synthesis in the ciliary body. Pilot studies have suggested that metipranolol is as effective as timolol maleate, but is significantly less expensive than trade name timolol preparations, but not the generically labeled products. Metipranolol has been useful for the management of primary open angle glaucoma in cats.

Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.3% solution. While problems have rarely been noted in veterinary medicine, ophthalmic beta blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Metipranolol Solution 0.3%: 2, 5, & 10 mL; *OptiPranolol®* (Bausch & Lomb); (Rx)**TIMOLOL MALEATE**

(tye-moe-lole)

Indications/Pharmacology

Timolol maleate is used primarily to prevent the development of primary glaucoma in the contralateral eye of a dog which has developed primary glaucoma in one eye. It only reduces intraocular pressure 3–10 mmHg and, therefore is of minimal usefulness in patients requiring treatment of primary acute congestive glaucoma. Timolol's mechanism of action: decreases cyclic-AMP synthesis in non-pigmented ciliary epithelium resulting in decreased aqueous humor production. It may also cause slight miosis in dogs and cats. Timolol maleate is rarely used alone but is combined with dorzolamide solution (*Cosopt®*). Caution is advised with use of Beta blocking agents in cats with concurrent asthma. As timolol maleate is now available in generic form, it is the primary Beta blocker agent now used.

Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.5% solution. The 0.25% concentration has minimal efficacy in animals and is not worth using. While problems have rarely been noted in veterinary medicine, ophthalmic beta blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Timolol Maleate 0.25% (see dosage above) or 0.5% Solution: 2.5, 5, 10, & 15 mL *Ocumeter*® bottles; *Timoptic*® (MSD); *Istalol*® (ISTA Pharmaceuticals); generic; (Rx)Timolol Maleate 0.5% and Dorzolamide 2% Solution: 5 mL & 10 mL *Ocumeter*® bottles, *Cosopt*® (MSD); (Rx)**Carbonic Anhydrase Inhibitors****BRINZOLAMIDE HCL**

(brin-zoh-la-mide)

Indications/Pharmacology

Brinzolamide is chemically similar to dorzolamide and reduces aqueous humor production by altering H⁺/Na⁺ active transport mechanisms associated with aqueous humor production in the ciliary epithelial cells. It can be used as a substitute for dorzolamide and some patients that exhibit excessive topical irritation following application of dorzolamide drops, tolerate brinzolamide better or vice versa. Cats seem to be particularly sensitive to irritation from topical dorzolamide and often brinzolamide can be used in these patients. Comparative data is available suggesting that brinzolamide and dorzolamide are equally effective in animal patients.

Suggested Dosages/Precautions/Adverse Effects

One drop three times daily is the standard treatment frequency, adjusted based on clinical response. May also cause stinging upon application like dorzolamide.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Brinzolamide HCl 1% solution: 2.5, 5, 10 & 15 mL containers; *Azopt*® (Alcon); (Rx)**DORZOLAMIDE HCL**

(dor-zole-a-mide)

Indications/Pharmacology

Dorzolamide is often used in the contralateral eye of a dog with primary glaucoma to prevent development of bilateral disease. It is also an excellent agent to consider for most secondary glaucomas in dogs and cats because it has no effect on pupil size. Like the related oral carbonic anhydrase inhibitors (dichlorphenamide or *Daranide*®, methazolamide or *Neptazane*®), dorzolamide decreases aqueous humor production by the ciliary body epithelium by altering pH and affecting the H⁺/Na⁺ active transport exchange mechanism. Oral carbonic anhydrase inhibitors cause numerous systemic side effects such as metabolic acidosis and panting, diarrhea, vomiting, anorexia and others, all of which can be avoided with topical carbonic anhydrase inhibitors.

Suggested Dosages/Precautions/Adverse Effects

One drop three times daily is the standard treatment frequency, adjusted based on clinical response. Dorzolamide may cause stinging upon topical application, particularly in cats. Approximately 5–10% of humans will experience irritation with use of topical dorzolamide.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**Dorzolamide HCl 2% Solution: 5, 10 & 15 mL; *Trusopt*® (Merck); (Rx)Timolol Maleate 0.5% and Dorzolamide 2% Solution: 5 & 10 mL *Ocumeter*® bottles, *Cosopt*® (Merck); (Rx)**Prostaglandins (Ophthalmic)****LATANAPROST, BIMATOPROST, TRAVOPROST**

(la-ta-noe-prost), (bi-ma-toe-prost), (tra-voe-prost)

Indications/Pharmacology

Prostaglandin analog drugs reduce intraocular pressure by increasing outflow of aqueous humor via the uveoscleral pathway. The major outflow mechanism in animals and people is through the iridocorneal angle, termed the “conventional outflow mechanism”. A species variable alternative pathway directly across the surface of the iris into the iridal venous supply accounts for some outflow in people and animals. The horse apparently has the highest uveoscleral outflow of the domestic species studied. Latanoprost was the first drug marketed in this class. Prostaglandin analogues are an exciting class of topical medications for patients with glaucoma because they increase the alternative outflow of aqueous which logically would seem superior to reducing production or attempting to increase outflow through a failing conventional outflow system.

Latanoprost is marketed for once daily usage in people and clinical studies show reduced effectiveness when once daily treatment is exceeded. Despite this report in people, many canines are started on once daily treatment but with the progression of their glaucoma, further pressure management can be noted with twice daily administration. The canine uveal tract apparently metabolizes latanoprost at a rate higher than humans because the IOP reduction is profound, but only for 12–15 hours in most dogs. Latanoprost will provide the greatest amount of pressure reduction in canine primary glaucoma cases compared with any other single oral or topical agent. It is even more effective in combination with topical or oral carbonic anhydrase inhibitors. Latanoprost has been used in veterinary ophthalmology to treat primary and select secondary glaucomas in the dog although clinicians should assess the possibility of profound miosis associated with the use of this medication in their secondary glaucoma cases. Latanoprost has not been found to be useful in the management of glaucoma in cats.

0.003% bimatoprost (*Lumigan*®) and 0.004% travoprost (*Travatan*®) are similar to latanoprost both in mechanism of action and clinical indications. Since latanoprost does not seem to be effective for most forms of feline glaucoma, it is not likely bimatoprost or travoprost will prove effective in these cases either.

Suggested Dosages/Precautions/Adverse Effects

One drop of latanoprost is applied in the PM initially, but with progression of the glaucoma, twice daily treatment schedules will provide additional reduction in intraocular pressure. Latanoprost may cause topical irritation. Conjunctival hyperemia is commonly noted in patients using this medication. A direct stimulation of iris melanocytes results in excess melanin production in the iris of people using this medication, causing a dark brown color change to the iris. Profound miosis is noted with the use of latanoprost in dogs and cats.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Latanoprost 0.005% Solution: 2.5 mL; *Xalatan*® (Pharmacia & Upjohn); (Rx). Store under refrigeration until use; at room temp for 6 weeks after opened.

Bimatoprost 0.03% Solution; *Lumigan*® (Allergan); (Rx)

Travoprost 0.004% Solution; *Travatan*® (Alcon); (Rx)

Miscellaneous Agents For Treatment of Glaucoma**EPINEPHRINE, TOPICAL**

(OPHTHALMIC)

(ep-i-nef-rin)

Indications/Pharmacology

Epinephrine (usually in combination with pilocarpine due to epinephrine's mydriatic effects) is usually used as a preventative measure to prevent glaucoma in the unaffected eye. Epinephrine acts on both alpha and beta adrenergic receptors, thereby causing conjunctival decongestion, transient mydriasis (less so in cats) and decreased IOP (intraocular pressure). Decreased IOP is probably due primarily to increased aqueous humor outflow, but decreased aqueous humor production may occur secondary to vasoconstriction.

Suggested Dosages/Precautions/Adverse Effects

One drop 2–3 times daily in the unaffected eye. Epinephrine may cause ocular discomfort upon instillation.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Epinephrine (HCl) Solution: 0.25%, 0.5%, 1% & 2%: 10 or 15 mL btl; *Epifrin*® (Allergan), *Glaucan*® (Alcon); (Rx)

Epinephrine (Borate) Solution: 0.5%, 1% & 2%: 7.5 mL btl; *Eppy/N*® (Pilkington/Barnes-Hind), *Epinal*® (Alcon); (Rx)

Epinephrine Bitartrate 1% in combination with Pilocarpine HCl Solution: 1%, 2%, 3%, 4% or 6%; *E-Pilo-1*® -2, -3, -4, -6 (Iolab); *P1 E1*® (Alcon); (Rx)

Mydriatic-Cycloplegic-Vasoconstrictors**CYCLOPENTOLATE**

(sy-e-kloe-pen-toe-late)

Indications/Pharmacology

Cyclopentolate is an anticholinergic agent that induces relaxation of the sphincter of the iris and the ciliary muscles. When applied topically to the eyes, it causes a rapid, intense cycloplegic and mydriatic effect that is maximal in 15–60 minutes; recovery usually occurs within 24 hours. The cycloplegic and mydriatic effects are slower in onset and longer in duration in animal patients who have darkly pigmented irises. Cyclopentolate is used mainly to produce mydriasis and cycloplegia for diagnostic purposes.

Suggested Dosages/Precautions/Adverse Effects

1 drop instilled in the eye(s), followed by a second drop 5 minutes later, if necessary. Drops should be administered 40–50 minutes prior to diagnostic procedure. Cyclopentolate increases intraocular pressure and should not be used in animals with glaucoma. Slight stinging is noted with the higher (1%) concentration of the drug.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Cyclopentolate Solution 0.5, 1, & 2%: in 2, 5 & 15 mL bottles: *AK-Pentolate*® (Akorn); *Cyclogyl*® (Alcon); generic; (Rx)

PHENYLEPHRINE HCL

(OPHTHALMIC)

(fen-il-ef-rin)

Indications/Pharmacology

Phenylephrine is a vasoconstrictor used to differentiate conjunctival vascular injection (blanches with phenylephrine application) versus deep episcleral injection (blanches incompletely) associated with uveitis, glaucoma, or scleritis. It is also used prior to conjunctival surgery to reduce hemorrhage and in combination with atropine prior to cataract or other intraocular surgeries that require maximal pupillary dilation. Phenylephrine can be used to confirm the diagnosis of Horner's syndrome. Dilution of 2.5% phenylephrine solution with saline (1:10) produces a 0.25% solution. Normal eyes will not demonstrate mydriasis in response to this low concentration of phenylephrine. Third order Horner's syndrome of greater than two weeks duration is associated with receptor up regulation and therefore a response to 0.25% phenylephrine is noted. In this way, the diagnosis of Horner's is confirmed and a suggestion as to whether or not the condition is 2nd or 3rd order in nature.

In dogs, maximum mydriasis persists for about 2 hours and effects may last for up to 18 hours. Phenylephrine has significant alpha adrenergic effects (vasoconstriction and pupillary dilation) and minimal effects on beta receptors. When used alone, phenylephrine is reportedly not efficacious in the cat unless used with other mydriatics.

Suggested Dosages/Precautions/Adverse Effects

For diagnosis and characterization of Horner's syndrome: Apply 0.25% solution (see above) in both eyes. If there is a response in the miotic eye; 3rd order. If no response in 20–30 minutes, apply 2.5% solution; if there is a response in both eyes it confirms Horner's and probably is 2nd order.

For treatment of Horner's syndrome: Treatment is indicated only if patient experiences visual difficulty because third eyelid is elevated over pupil; then given on an as needed basis with an average duration of effect of 3–6 hours.

Prior to cataract or intraocular surgery: 2.5% or 10% given every 15 minutes for two hours. Smaller animals (e.g., cats and dogs weighing <5kg) are more susceptible to life-threatening systemic effects on blood pressure and cardiac rhythm and preoperative use of phenylephrine in these animals is generally not recommended. In larger animals, repeated dosing is also associated with cardiovascular adverse effects.

Local discomfort may occur after instillation and chronic use may lead to inflammation. In some species (cat, rabbit, humans) transient stromal clouding may occur if used when corneal epithelium is damaged.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Phenylephrine HCl 0.12% Solution: 15 mL or 20 mL bottles; generic; (OTC)

Phenylephrine HCl 2.5% Solution: 2, 5 or 15 mL bottles; generic; (Rx)

Phenylephrine HCl 10% Solution: 1, 2, 5 or 15 mL bottles; *Neo-Synephrine*® (Sanofi Winthrop), generic; (Rx)

ATROPINE SULFATE

(OPHTHALMIC)

(a-troe-peen)

Indications/Pharmacology

Atropine, when used topically on the eye, acts by blocking the cholinergic receptors of the sphincter muscle of the iris and the ciliary body to cause mydriasis (pupillary dilation) and accommodation paralysis (cycloplegia). Atropine controls pain secondary to corneal and uveal disease; to maximally dilate the pupil prior to intraocular surgery; to dilate the pupil and prevent pupillary block in glaucoma and uveitis. In the dog, atropine causes maximal mydriasis in about 1 hour and it may persist for up to 120 hours. Cats also show a delayed onset of action and mydriasis may persist for up to 144 hours (dose dependent). Atropine is particularly long acting in horses and may last days to weeks.

Atropine may be used in combination with 10% phenylephrine to achieve mydriasis and cycloplegia in cases of anterior uveitis. Atropine may also be used in uveitis to break up synechiae.

Suggested Dosages/Precautions/Adverse Effects

Ointments or drops are routinely used in dogs. One percent is commonly used, but 2% solutions may be required in severe cases of uveitis. Ointments are generally used in cats to prevent hypersalivation associated with the bitter taste of this medication. Dosage frequencies are variable depending on the condition and its severity. Commonly, atropine is given as one drop 2–3 times a day or every

other day until pupillary dilation is achieved and once daily thereafter to maintain this response.

Atropine may precipitate acute, congestive primary glaucoma in dogs predisposed to primary glaucoma; do not use in primary glaucoma. Repeated topical application prior to surgery can result in systemic atropine toxicosis (mania, hyperthermia, etc.). Salivation may result in dogs as well as cats (see above) secondary to the bitter taste. Atropine may also decrease tear production in small animals.

Reportedly, very frequent treatment with atropine may induce colic in horses secondary to systemic absorption and atropine's vagal parasympathetic effects. However, clinically this effect is only rarely noted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Atropine Sulfate Ophthalmic Ointment: 10 mg/gm (1%) in 3.5 gm tubes; *Atrophate*® (Schering-Plough); (Rx)

HUMAN-LABELED PRODUCTS:

Atropine Sulfate Ophthalmic Ointment: 5 mg/gm (0.5%), & 10 mg/gm (1%) in 3.5 gm tubes; various trade names & generic; (Rx)

Atropine Sulfate Ophthalmic Solution: 0.5%, 1%, and 2% in unit dose droppers, 2, 5, & 15 mL bottles; various trade names & generic; (Rx)

TROPICAMIDE

(troe-pik-a-mide)

Indications/Pharmacology

Tropicamide, like atropine, causes mydriasis and cycloplegia, but has more mydriatic than cycloplegic activity. Tropicamide has a more rapid onset (maximum mydriasis in 15–30 minutes) of action and a shorter duration of action (pupil returns to normal in 6–12 hours in most animals) than does atropine, thereby making it more useful for funduscopic examinations. In dogs, intraocular pressure is apparently not affected by tropicamide. Tropicamide is also indicated following cataract removal to prevent synechiae formation that is associated with post-cataract atropine administration. As the half-life of tropicamide is shorter than that of atropine, this allows iris contraction preventing synechial adhesions.

Suggested Dosages/Precautions/Adverse Effects

Once or twice application to eye, prior to exam. Following cataract surgery: apply 2–3 times daily to keep pupil constantly changing in size and reduce formation of synechiae associated with prolonged pupillary dilation (atropine).

Tropicamide is less effective in pain control (cycloplegia) than atropine.

Tropicamide may cause salivation, particularly in cats and may also sting when applied. Tropicamide may precipitate acute congestive glaucoma in predisposed patients.

Dosage Forms/Regulatory Status

VETERINARY APPROVED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Tropicamide Solution 0.5% and 1%: 2 mL & 15 mL bottles; *Mydrin*® (Alcon), *Opticyl*® (Optopics), *Tropicacyl*® (Akorn), generic; (Rx)

Anti-inflammatory/Analgesic Ophthalmic Agents

Mast Cell Stabilizers, Antihistamines, Decongestants

CROMOLYN SODIUM

(OPHTHALMIC)

(*kroe-moe-lin*)

Indications/Pharmacology

Cromolyn sodium is a mast cell stabilizing agent that blocks release of histamine and slow-reacting substance of anaphylaxis from mast cells following antigen recognition. Similar to lodoxamine tromethamine, cromolyn sodium has no intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition or other anti-inflammatory properties. Mast cell stabilizing agents are most useful in animal patients suffering from allergic conjunctivitis.

Suggested Dosages/Precautions/Adverse Effects

For relief of seasonal allergy, one drop 2–6 times daily. A stinging sensation is noted in a low percentage of people using this medication.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Cromolyn Sodium 4% Solution: 2.5, & 10 mL; *Crolom*® (Bausch & Lomb); (Rx)

LODOXAMINE TROMETHAMINE

(*loe-dox-a-mide*)

Indications/Pharmacology

Lodoxamine tromethamine is a mast cell stabilizer that inhibits Type I hypersensitivity responses by preventing antigen mediated histamine release. Lodoxamine stabilizes mast cells by blocking calcium influx into the cell upon antigen recognition, thereby blocking histamine release. Lodoxamine has no intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition or other anti-inflammatory properties. Lodoxamine is used in people for management of conjunctivitis associated with seasonal allergy and other histamine mediated disorders. In veterinary medicine, lodoxamine tromethamine has been used in horses and small animal patients with presumed allergic conjunctivitis.

Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 2–4 times daily. A stinging sensation is noted in a low percentage of people using this medication.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lodoxamine Tromethamine 0.1%: 10 mL; *Alomide*® (Alcon); (Rx)

OLOPATADINE HCL

(*oh-loe-pa-ta-deen*)

Indications/Pharmacology

Olopatadine HCl is a selective H₁ receptor antagonist and inhibitor of histamine release from mast cells. It is marketed for topical use to alleviate symptoms of allergic conjunctivitis in humans and is thought to be safe for use in children three years of age and older. Olopatadine, upon topical application in humans, was shown to have very limited systemic absorption. It was detectable in the milk of nursing rats, after topical application, and like most medications should be avoided in pregnant or nursing animals.

Suggested Doses/Precautions/Adverse Effects

Olopatadine eye drops are applied as needed in people for temporary relief of itchiness associated with seasonal allergy. They can be used in dogs two to three times daily for allergic conjunctivitis.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Olopatadine HCl ophthalmic solution 0.1%; *Patanol*® (Alcon); (Rx)

Non-Steroidal Antiinflammatory Agents

BROMFENAC

(*brome-fen-ak*)

Indications/Pharmacology

Bromfenac is a nonsteroidal anti-inflammatory drug (NSAID) by virtue of its ability to block prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Bromfenac is indicated for treatment of postoperative inflammation in patients who have undergone cataract extraction.

Suggested Doses/Precautions/Adverse Effects

One drop twice daily. Bromfenac is contraindicated in patients with known hypersensitivity to any ingredient in the formulation. Bromfenac ophthalmic solution contains sodium sulfite, a sulfite known to cause allergic reactions especially in asthmatic patients. Caution should be exercised when utilizing bromfenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity. There have been reports that ocularly applied NSAIDs may cause increased swelling of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or corneal perforation. Use of bromfenac should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown. Post marketing experience with topical NSAIDs suggests that use more than 24 hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Bromfenac should be used with caution in patients with known bleeding tendencies or who are receiving other medications, which may prolong bleeding time. The most commonly reported adverse experiences reported following use of bromfenac include:

abnormal sensations in the eye, conjunctival hyperemia, eye irritation (including burning/stinging), eye pain, eye pruritus, eye redness, headache, and iritis. These events were reported in 2–7% of human patients.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Bromfenac 0.09% solution: 7.5 mL, 10 mL; *Xibrom*® (ISTA Pharmaceuticals) (Rx). Store at room temperature.

DICLOFENAC SODIUM

(OPHTHALMIC)

(dye-*kloe*-fen-ak)

Indications/Pharmacology

Diclofenac sodium is a phenylacetic acid that inhibits cyclooxygenase, inhibiting prostaglandin synthesis. Diclofenac sodium topical solution reduces inflammation following cataract extraction in people and counteracts photophobia in humans having refractive corneal surgery. In veterinary medicine, diclofenac sodium is used for treatment of uveitis following surgery on the eye or other causes of uveitis especially when corneal infection is suspected or in diabetic patients whose insulin regulation could be altered by the systemic uptake of topical corticosteroids. Diclofenac can be combined with topical corticosteroids for better control of uveitis in animals when the condition is severe.

Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20 minute intervals. One drop four times daily following cataract surgery or for the treatment of uveitis. Caution should be used when applying any anti-inflammatory agent on the cornea in the face of corneal stromal infection because of the positive role inflammation plays in the immune response to microbial invasion of tissue. A stinging sensation is noted in 15% of people using this medication.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Diclofenac Sodium 0.1% Solution: 2.5 & 5 mL; *Voltaren*® (Novartis); (Rx)

FLURBIPROFEN SODIUM

(flure-*bi*-proe-fen)

Indications/Pharmacology

Flurbiprofen is a non-steroidal anti-inflammatory agent that probably acts by inhibiting the cyclo-oxygenase enzyme system, thereby reducing the biosynthesis of prostaglandins. Prostaglandins may mediate certain kinds of ocular inflammation. They may disrupt the blood-aqueous humor barrier, cause vasodilation, increase intraocular pressure and leukocytosis, and increase vascular permeability. Prostaglandins may also cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Flurbiprofen can inhibit this intraocular miosis and may also be useful in the management of uveal inflammation (usually in addition to topical steroids).

Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20 minute intervals.

Because flurbiprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with infected corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shunted into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of flurbiprofen prior to cataract surgery has resulted from these studies.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Flurbiprofen Sodium 0.03% Solution: 2.5, 5 & 10 mL btl; *Ocufen*® (Allergan); generic; (Rx)

KETOROLAC TROMETHAMINE

(OPHTHALMIC)

(kee-toe-*role*-ak)

Indications/Pharmacology

Ketorolac tromethamine is a pyrrolol-pyrrole nonsteroidal anti-inflammatory agent that inhibits prostaglandin formation. Prostaglandins mediate inflammation within the eye by disrupting the blood-aqueous barrier, inducing vasodilation and increasing intraocular pressure. Prostaglandins may also cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Ketorolac tromethamine is marketed for use before cataract extraction in human patients (to prevent miosis during surgery) and for control of post surgical inflammation, especially following cataract surgery. It is also approved for management of conjunctivitis associated with seasonal allergy in people. In veterinary medicine, ketorolac tromethamine is primarily used to control surgical or nonsurgical uveitis particularly in cases with concurrent corneal bacterial infection or ulceration when topical corticosteroids are contraindicated. It is also used in diabetic patients, especially smaller patients, adversely affected by systemic uptake of topically applied corticosteroids. Nonsteroidal agents like ketorolac tromethamine can be combined with topical steroids in patients with severe uveal inflammation.

Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20 minute intervals. One drop four times daily following cataract surgery or for the treatment of uveitis or management of allergic conjunctivitis.

The manufacturer indicates that ketorolac tromethamine does not enhance the spread of preexisting corneal fungal, viral or bacterial infections in animal models. Ketorolac tromethamine does not in and of itself induce postoperative pressure elevation other than that which frequently follows cataract extraction in people and animals.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ketorolac Tromethamine Solution 0.5%: 3, 5, & 10 mL; *Acular*® (Allergan); (Rx)

NEPAFENAC

(ne-pa-fen-ak)

Indications/Pharmacology

Nepafenac is a nonsteroidal anti-inflammatory and analgesic pro-drug. After topical ocular dosing, nepafenac penetrates the cornea and is converted by ocular tissue hydrolases to amfenac, a nonsteroidal anti-inflammatory drug. Amfenac is thought to inhibit the action of prostaglandin H synthase (cyclooxygenase), an enzyme required for prostaglandin production. Nepafenac is indicated for the treatment of pain and inflammation associated with cataract surgery.

Suggested Dosages/Precautions/Adverse Effects

One drop three times daily. Shake well before use.

Nepafenac is contraindicated in patients who have demonstrated hypersensitivity to any of the ingredients in the formulation or to other NSAIDs. Caution should be exercised when utilizing bromfenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity.

There have been reports that ocularly applied NSAIDs may cause increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or corneal perforation. Use of bromfenac should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown. Post marketing experience with topical NSAIDs suggests that use more than 24 hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Bromfenac should be used with caution in patients with known bleeding tendencies or who are receiving other medications, which may prolong bleeding time. In controlled clinical studies, the most frequently reported ocular adverse events following cataract surgery were capsular opacity, decreased visual acuity, foreign body sensation, increased intraocular pressure, and sticky sensation. These events occurred in approximately 5–10% of patients. Other ocular adverse events occurring at an incidence of approximately 1–5% included conjunctival edema, corneal edema, dry eye, lid margin crusting, ocular discomfort, ocular hyperemia, ocular pain, ocular pruritus, photophobia, tearing and vitreous detachment. Some of these events may be the consequence of the cataract surgical procedure. Non-ocular adverse events reported at an incidence of 1–4% included headache, hypertension, nausea/vomiting, and sinusitis. Nepafenac ophthalmic suspension may be administered in conjunction with other topical ophthalmic medications such as beta-blockers, carbonic anhydrase inhibitors, alpha-agonists, cycloplegics, and mydriatics.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Nepafenac Ophthalmic Suspension: 0.1% in 3 mL; *Nevanac*® (Alcon); (Rx). Shake well and store at room temperature.

SUPROFEN

(su-pro-phen)

Indications/Pharmacology

Suprofen is a non-steroidal anti-inflammatory agent similar to flurbiprofen. Suprofen and flurbiprofen are phenylalkanoic acids that inhibit the cyclo-oxygenase enzymes responsible for conversion of arachadonic acid from cell membranes into various prostaglandins. These prostaglandins mediate certain aspects of ocular inflammation including disruption of the blood-aqueous barrier, uveal vasodilation, increases in intraocular pressure, and leakage of white blood cells and protein from uveal vessels into the aqueous humor. Prostaglandins cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Suprofen can inhibit this intraocular miosis and may also be useful in the management of uveal inflammation (usually in addition to topical steroids).

Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20 minute intervals.

Because suprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with bacterial corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shunted into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of suprofen or flurbiprofen prior to cataract surgery has resulted from these studies.

Dosage Forms/Regulatory Status

Steroidal Anti-inflammatory Agents

CORTICOSTEROIDS, TOPICAL

(OPHTHALMIC)

PREDNISOLONE ACETATE

DEXAMETHASONE

LOTEPREDNOL ETABONATE

(see also Antibiotic & Corticosteroid Combinations)

Indications/Dosages/Precautions

Topical corticosteroids are used to treat diseases of the eye involving the conjunctiva, sclera, cornea, and anterior chamber. Penetration of topically applied corticosteroids into the eyelids is poor as is penetration to the posterior segment of the eye. Corticosteroid-responsive conditions affecting these areas are usually managed with systemically administered agents (with or without adjunctive topically applied medications).

Conjunctivitis in animals is often treated symptomatically, particularly during the first occurrence of the condition for any particular patient. Antibiotic agents with hydrocortisone or dexamethasone, or antibiotic agents alone initially, are used for conjunctivitis

in the dog and the horse. Allergic and eosinophilic conjunctivitis are rare diagnoses in the cat. Topically applied corticosteroids should not be used to treat conjunctivitis in cats. Herpes virus is the most common feline conjunctival pathogen and topically applied steroids can induce prolonged disease, steroid dependency and corneal complications including ulcerative keratitis and/or corneal sequestrum formation.

Inflammatory conditions of the canine sclera and episclera include episcleritis, scleritis, nodular granulomatous episclerokeratitis, Collie granuloma and others. Potency and penetration of corticosteroid agents is important in the management of these conditions. Dexamethasone sodium phosphate ointment is often employed and the relatively reduced penetration of the fibrous ocular tunics of this medication compared with that of 1% prednisolone acetate ophthalmic suspension is made up for by increased contact time of the ointment form of this drug and by the increased potency of dexamethasone (30X cortisone) relative to prednisolone (4–5X cortisone). Dexamethasone products alone (without antibiotics) are becoming increasingly scarce in the marketplace and because of this, dexamethasone is often used in combination with an antibiotic for availability reasons only. Four times daily treatment is often the initial frequency with tapering paralleled to clinical response. Topical treatment is often used following subconjunctival injection of corticosteroid agents into or adjacent to the lesion (if focal). Systemic steroid treatment is usually not necessary.

Non-ulcerative inflammatory conditions of the cornea of animals include chronic superficial keratitis (pannus) of the German Shepherd and other breeds, eosinophilic keratitis of the cat and certain, often poorly understood, keratopathies of the equine, including *Onchocerca* related keratitis. German Shepherd pannus may be better managed using cyclosporine ophthalmic solution or ointment with or without concurrent topical steroids initially followed by long term management with cyclosporine ophthalmic alone (see cyclosporine ophthalmic). Eosinophilic keratitis is often treated with subconjunctival corticosteroids in addition to topical 0.1% dexamethasone ophthalmic ointment or solution or 1% prednisolone acetate ophthalmic suspension 4 times daily, tapering the dosage frequency based on clinical response. Recent research reveals that eosinophilic keratitis may be an unusual immune response to latent feline herpes virus in the corneal stroma, calling into question the value of topical steroids in the management of a disease with an infectious etiology. Despite new information pertaining to possible causes of eosinophilic keratitis in the cat, the condition continues to be well managed in most cases with infrequent topical corticosteroid treatment. Non-ulcerative, immune mediated and/or parasitic equine keratopathies are treated with 0.1% dexamethasone ointment 4 times daily with tapering of the treatment frequency based on the clinical response.

Corticosteroids are also used to manage anterior uveal inflammatory disease of companion animals. In small animals, 1% prednisolone acetate ophthalmic suspension is generally used for this purpose because of superior penetration into the anterior segment of the eye in comparison with dexamethasone products. The frequency of treatment depends on the severity of the condition. Severe anterior uveitis can be treated with subconjunctival corticosteroids given in combination with hourly topical corticosteroids with reevaluation performed again 24 hours after beginning treatment. Moderate to mild uveitis and that found following surgery of the anterior segment is often treated initially at the QID level with tapering based on clinical response. Anterior uveitis in animals can often be associated with an underlying systemic infectious or neoplastic condition in animals. Clinicians are advised to evaluate the patient for generalized infectious or neoplastic conditions prior to or concurrent with a course of corticosteroid antiinflammatory

therapy, particularly if the condition dictates systemic treatment with these agents in combination with subconjunctival and topical treatment. Uveitis has also been successfully treated utilizing subconjunctival injections of triamcinolone acetonide. As commercially available triamcinolone injections are preserved with benzyl alcohol, veterinary ophthalmologists centrifuge triamcinolone injections and remove the alcohol-containing supernatant vehicle. An equal volume of non-preserved sodium chloride injection is then utilized to reconstitute the remaining triamcinolone to provide for an acceptable subconjunctival injection. Uveitis in the equine species is often treated with either 1% prednisolone acetate ophthalmic suspension or with 0.1% dexamethasone ointment. Many clinicians prefer to use the ointment because of increased contact time and potency and the logistics of frequent treatment of this species. 1% prednisolone acetate can be passed through a subpalpebral lavage catheter very frequently to treat equine patients with anterior uveitis when necessary.

Pred Forte®, *Econopred Plus®* or generic 1% prednisolone acetate ophthalmic suspension are the prednisolone products most used by veterinary ophthalmologists. There are few indications for *Econopred®* or *Pred Mild®* in veterinary ophthalmology.

Inflammatory conditions of the posterior segment require systemic treatment because of poor penetration of topically applied agents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Prednisolone Acetate Drops: 0.12% Suspension: *Pred Mild®* (Allergan); 0.125% Suspension: *Econopred®* (Alcon); 1% Suspension: *Econopred Plus®* (Alcon); *Pred Forte®* (Allergan), generic; (Rx)

Prednisolone Sodium Phosphate Drops: 0.125 & 1% Solution; (various); (Rx)

Prednisolone (0.25%) and Atropine (1%) Drops in 5 mL btl; *Mydraped®* (Alcon); (Rx)

Loteprednol Etabonate Ophthalmic Suspension: 0.2% in 5 mL, 10 mL; *Alrex®* (Bausch and Lomb); (Rx). Shake well and store at room temperature. Do not freeze.

Also available: Fluorometholone or Medrysone drops

Other routes of administration: Systemically administered corticosteroids (usually orally) may be indicated for non-infectious inflammatory ocular conditions and following intraocular surgery. Subconjunctival steroids are useful in anterior segment inflammatory disease and following cataract surgery and intraocular glaucoma surgery. Subconjunctival steroids may be absorbed systemically and should be used with caution in patients with endocrinopathies (e.g., diabetes mellitus) or infectious diseases. Even frequent topical steroid application in small animal patients under 20 kg can cause difficulties with diabetes mellitus regulation and after the peak inflammatory response has been suppressed, nonsteroidal antiinflammatory drugs should be considered for ongoing maintenance treatment.

Ophthalmic Analgesics (Topical)

MORPHINE SULFATE (TOPICAL)

(*mor-feen*)

Indications/Pharmacology

A recent study showed that topical use of 1% morphine sulfate solution in dogs with corneal ulcers provided analgesia and did not interfere with normal wound healing. Both mu and delta opioid receptors were identified in normal corneas of dogs, although the mu receptors were present only in small numbers. Dogs treated with morphine sulfate 1% topical solution had significantly less blepharospasm and lower esthesiometer readings than did control dogs. Morphine sulfate is a Schedule II controlled substance.

Suggested Dosages/Precautions/Adverse Effects

1 drop of 1% morphine sulfate solution in the affected eye(s) three times daily. Preserved solutions of morphine should not be used.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

A 1% morphine sulfate ophthalmic solution may be compounded by utilizing the preservative-free morphine 2.5% injectable solution diluted with sterile saline observing appropriate aseptic technique.

NALBUPHINE (TOPICAL)

(*nal-byoo-feen*)

Indications/Pharmacology

A review of the literature reveals that solutions of topical nalbuphine were used clinically to provide analgesia and reduce ophthalmic pain in humans as early as 1983. Nalbuphine hydrochloride is a potent analgesic. Its analgesic potency is essentially equivalent to that of morphine on a milligram basis. Receptor studies show that nalbuphine hydrochloride binds to mu, kappa, and delta receptors, but not to sigma receptors. Nalbuphine hydrochloride is primarily a kappa agonist/partial mu antagonist analgesic. Nalbuphine hydrochloride by itself has potent opioid antagonist activity at doses equal to or lower than its analgesic dose. When administered following or concurrent with mu agonist opioid analgesics (e.g., morphine, oxymorphone, fentanyl), nalbuphine hydrochloride may partially reverse or block opioid-induced activity from the mu agonist analgesic. Nalbuphine hydrochloride may precipitate withdrawal in patients dependent on opioid drugs. Nalbuphine hydrochloride should be used with caution in patients who have been receiving mu opioid analgesics on a regular basis. Nalbuphine is not commercially available for ophthalmic use, but may be prepared through compounding.

Suggested Dosages/Precautions/Adverse Effects

One drop two to six times daily as needed for corneal pain. Do not use in conjunction with topical morphine as nalbuphine will reverse the effects of morphine at the *mu* receptor.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

The 10 mg/mL (1%) nalbuphine injection may be applied as an ophthalmic solution. A 1% nalbuphine ophthalmic solution may also be compounded by utilizing nalbuphine 20 mg/mL injectable solution diluted with 1:1 with sterile saline observing appropriate aseptic technique.

Antimicrobial Ophthalmic Therapy

Antibiotics, Single & Combination Agents

Indications/Pharmacology; General Use Considerations

Topical antibiotic agents are commonly used to treat conjunctivitis and ulcerative keratitis complicated by bacterial infection of the corneal stroma. These agents are also used to prevent infection following surgery of the eyelids, conjunctiva, cornea, and the anterior segment. Conjunctivitis in animals is a common clinical entity. Because in most instances the condition does not threaten vision, it is often treated symptomatically with antibiotic agents or antibiotic agents in combination with topical steroids (see antibiotic/corticosteroid combination agents). Conjunctivitis is an exclusion diagnosis in animals, ruling out other causes for ocular discomfort and discharge, including anterior uveitis, glaucoma and inflammatory disease of the sclera, episclera and cornea. Triple antibiotic products (neomycin, bacitracin and polymyxin B) are often employed for this purpose, with or without hydrocortisone, because these drugs are not used systemically and because the combination of antibiotics is broad spectrum. Triple antibiotic or triple antibiotic HC is often used in dogs 4 times daily for 1 to 2 weeks for conjunctivitis. Chronic or recurrent cases of conjunctivitis would indicate further diagnostic evaluation to determine an underlying cause. Oxytetracycline ophthalmic ointment is often used QID in cats for nonspecific or undiagnosed conjunctivitis; however, anaphylaxis from Polymyxin B in the commercially available product (*Terramycin*®) has been reported. The rationale for topical treatment is the efficacy of tetracycline for *Chlamydia* spp. and *Mycoplasma* spp., two infectious agents reported to cause conjunctivitis in the cat. Research evidence suggests that cats will not be cleared of *Chlamydia* spp. organisms dormant in the nasal and GI passages unless treated systemically with doxycycline at 25 mg twice daily by mouth for three weeks. Research evidence also shows that solid dosage forms of doxycycline are likely to become lodged in the esophagus of cats and result in esophageal erosions and subsequent strictures. Consequently, liquid dosage forms of doxycycline should be used when treating cats. Because cats may carry the organism in a dormant fashion it is recommended to treat all cats in a household when chlamydial conjunctivitis is diagnosed in one or more cats. Antibiotic agents with corticosteroids should not be used for the treatment of conjunctivitis in the cat. The majority of cases are related to primary or recurring infection with feline herpes virus and recent evidence indicates that topical or systemic steroid therapy can potentially prolong the duration of the viral infection and result in corneal complications in cases which otherwise may have remained a conjunctival infection. Veterinary ophthalmologists are becoming increasingly concerned about sporadic reports of cats developing anaphylactic shock and death following application of triple antibiotic ointment to their eyes. Presumably this rare idiosyncratic reaction results from topical neomycin ir-

ritation and massive histamine release. Because of this often fatal anaphylactic reaction, many veterinary ophthalmologists do not use neomycin-containing products in cats. Triple antibiotic with or without hydrocortisone is often used to treat conjunctivitis in the equine species.

Antibiotic therapy for corneal disease varies from prophylactic therapy to prevent infection to treatment of established corneal infections. Following an acute superficial injury to the cornea in the dog or horse, treatment with triple antibiotic ointment or drops 4 times daily is usually sufficient to prevent bacterial infection of the corneal stroma. Because of the potential for anaphylactic reactions in cats, gentamicin has become the first choice antibiotic for preventing microbial infection following injury or surgery in the feline species. Reevaluation of the patient 24–48 hours after the injury is indicated. Progressive edema, pain, and white opacification of the cornea (cellular infiltrate) would suggest that the antibiotic protocol (agent and frequency) has failed to prevent bacterial infection.

Post surgical prophylactic medical treatment usually involves triple antibiotic agents (except in cats in which gentamicin is generally used) because of their broad spectrum and because they are not agents used systemically. Four times daily treatment is recommended. Ointments are commonly used after surgery of the eyelids, conjunctiva or cornea. Eye drops are usually used following surgery of the cornea or anterior segment. Bacterial infection of the anterior chamber alone is uncommon. Bacterial endophthalmitis carries a poor prognosis for saving vision or the globe in animals and is usually managed surgically in people. Gentamicin is sometimes used for prophylactic therapy of the equine species because of a greater number of gram negative organisms in the environment of this species. Tobramycin and the quinolones would not be considered for prophylactic treatment following surgery performed under sterile conditions.

CHLORAMPHENICOL

(OPHTHALMIC)

(klor-am-fen-i-kole)

Indications/Pharmacology

A broad spectrum antibiotic, chloramphenicol has the ability to cross the corneal barrier and enter the anterior chamber. However, there are very few infections that occur in the anterior chamber and if bacteria are actually present there, the blood ocular barrier is lost and systemically administered antibiotics can achieve therapeutic levels.

Because of the potential toxicity associated with chloramphenicol to humans, chloramphenicol's use in veterinary ophthalmology is becoming less widespread. It may be useful, however, in treating cats with suspected *Mycoplasma* or chlamydial conjunctivitis.

Suggested Dosages/Precautions/Adverse Effects

For prophylaxis following surgery or for cats with *Mycoplasma* or chlamydial conjunctivitis: One drop (or 1/4 inch strip if using ointment) four times daily. For established corneal infection: Application may be very frequent (up to hourly).

Chloramphenicol exposure in humans has resulted in fatal aplastic anemia. For this reason, this drug should be used with caution in veterinary patients and some ophthalmologists avoid its use entirely. Clients should be cautioned to use appropriate safeguards when applying the drug and avoiding contact with drops or solutions after application.

Labels state to not use longer than 7 days in cats, but *tid* application of ointment for 21 days to cats did not cause toxicity. Must not be used in any food producing animal.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Chloramphenicol 1% Ophthalmic Ointment in 3.5 gm tubes; *Chloromycetin*® (Parke Davis); *Chloroptic*® (Allergan); generic (Rx)

Chloramphenicol 0.5% Ophthalmic Drops in 7.5 mL; *Chloroptic*® (Allergan); generic (Rx). Refrigerate until dispensed. These products are sporadically available commercially and may need to be compounded by an appropriately trained compounding pharmacist.

CIPROFLOXACIN (OPHTHALMIC)

GATIFLOXACIN (OPHTHALMIC)

LEVOFLOXACIN (OPHTHALMIC)

MOXIFLOXACIN (OPHTHALMIC)

NORFLOXACIN (OPHTHALMIC)

OFLOXACIN (OPHTHALMIC)

Indications/Pharmacology

These fluoroquinolone ophthalmic antibiotics are primarily useful for established gram negative corneal infections. They are not recommended for prophylactic use prior to or after surgery. See the main enrofloxacin/ciprofloxacin monograph for additional pharmacologic information.

Clinicians are strongly cautioned regarding the development of retinal neurotoxicity at or above the formerly recommended systemic enrofloxacin dosage in cats. There are no reports at the time of writing of retinal toxicity in cats administered topical fluoroquinolone ophthalmic products.

Precautions/Adverse Effects

Ciprofloxacin may cause crusting or crystalline precipitates in the superficial portion of corneal defects. Other potential adverse effects with quinolones include: conjunctival hyperemia, bad taste in mouth, itching foreign body sensation, photophobia, lid edema, tearing keratitis and nausea. Allergic reactions have been reported with quinolone eye preps.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ciprofloxacin 3 mg/mL drops in 2.5 & 5 mL btl; *Ciloxan*® (Alcon); (Rx)

Ciprofloxacin:Dexamethasone 0.3%:0.1% drops in 7.5 mL btl; *Ciprodex*® (Alcon); (Rx)

Gatifloxacin 0.3% drops in 5 mL btl; *Zymar*® (Allergan); (Rx)

Levofloxacin 0.5% drops in 5 mL btl, *Quixin*® (JOM Pharmaceuticals); 1.5% drops, 5 mL btl; *Iquix*® (JOM Pharmaceuticals); (Rx)

Moxifloxacin 5 mg/mL drops: 3 mL & 6 mL btl; *Vigamox*® (Alcon); (Rx)

Norfloxacin 3 mg/mL drops in 5 mL btl; *Chibroxin*® (Merck); (Rx)

Ofloxacin 3 mg/mL drops in 5 mL btl; *Ocuflax*® (Allergan); (Rx)

GENTAMICIN (OPHTHALMIC)**TOBRAMYCIN (OPHTHALMIC)**

(jen-ta-mye-sin; toe-bra-mye-sin)

Indications/Pharmacology

The aminoglycosides are excellent drugs for gram negative or staphylococcal corneal infections. With frequent application, clinicians can establish corneal drug levels far in excess of MIC for most organisms without exceeding toxic systemic levels. Therefore, MIC reports may not be meaningful. Because of the high levels attainable, gentamicin usually exhibits similar efficacy to tobramycin, except in certain resistant gram-negative infections (e.g., *Pseudomonas aeruginosa*).

For serious gram negative or staphylococcal corneal ulcer infections, some ophthalmologists use cefazolin eye drops (compounded preparation 33 mg/mL – 50 mg/mL in artificial tears) in combination with gentamicin or tobramycin. Synergism may result.

Precautions/Adverse Effects

Hypersensitivity, and localized ocular toxicity (lid itching, swelling and conjunctival erythema) have been reported rarely. Mydriasis and conjunctival paresthesias may also occur.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Gentamicin Ophthalmic Ointment: 3 mg/g in 3.5 gm tubes; *Gentocin*® (Schering); (Rx). Approved for use in dogs and cats.

Gentamicin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Gentocin*® (Schering); (Rx). Approved for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

Gentamicin Ophthalmic Ointment: 3 mg/g in 3.5 gm tubes; *Garamycin*® (Schering); *Genoptic*® (Allergan); generic; (Rx)

Gentamicin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Garamycin*® (Schering); *Genoptic*® (Allergan); generic; (Rx)

Tobramycin Ophthalmic Ointment: 3 mg/g in 3.5 gm tubes; *Tobrex*® (Alcon); (Rx)

Tobramycin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Tobrex*® (Alcon); (Rx)

SULFACETAMIDE

(sul-fa-see-ta-mide)

Indications/Pharmacology

For the treatment of conjunctivitis and other superficial ocular infections due to susceptible microorganisms, and as an adjunctive in systemic sulfonamide therapy of trachoma, *Escherichia coli*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Streptococcus* (viridans group), *Haemophilus Muenzæ*, *Klebsiella* species and *Enterobacter* species. Topically applied sulfonamides do not provide adequate coverage against *Neisseria* species, *Serratia marcescens* and *Pseudomonas aeruginosa*. A significant percentage of staphylococcal isolates are completely resistant to sulfa drugs.

Precautions/Adverse Effects

For conjunctivitis and other superficial ocular infections: Instill one or two drops into the conjunctival sac(s) of the affected eye(s) every

two to three hours initially. Dosages may be tapered by increasing the time interval between doses as the patient responds. The usual duration of treatment is seven to ten days. Owners with sulfa allergies should be cautioned to avoid all contact with this medication.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Sulfacetamide Ophthalmic Solution 10%: 15 mL btl; *Sulf-10*®, *AK-10*® (Akorn); *Bleph-10*® (Allergan); (Rx)

Sulfacetamide Ophthalmic Ointment 10%: *Bleph-10*® (Allergan); (Rx)

**TETRACYCLINE/
OXYTETRACYCLINE**

(OPHTHALMIC)

(tet-ra-sye-kleen)/(ox-ee-tet-ra-sye-kleen)

Indications/Pharmacology

The tetracyclines are most useful in cats for the treatment of Chlamydial and Mycoplasma conjunctivitis as well as nonspecific or symptomatic therapy for undiagnosed (causative organism not determined) conjunctivitis in cats. While its use in dogs and horses is questionable, it may be useful in goats for Chlamydial/ Mycoplasma keratoconjunctivitis. At the time of publication, there are no commercially available ophthalmic dosage forms of tetracycline. There are, however, Veterinary-Labeled forms of oxytetracycline and Polymyxin B ophthalmic ointments (*Terramycin*®). It is again, important to note, that severe anaphylaxis, sometimes fatal, has been associated with topical Polymyxin and neomycin in cats and caution is recommended when using this product in cats.

Suggested Dosages/Precautions/Adverse Effects

For Chlamydial/Mycoplasma keratoconjunctivitis: Apply 4 times daily. Dramatic improvement should be noted in 3–4 days, but treatment should continue for 3–4 weeks for Chlamydia to break the reproductive cycle of this organism. Expect potential recurrence after discontinuation of topical treatment from organisms dormant in the nasal passage. As oral doxycycline has been documented to eliminate the carrier state of Chlamydia in cats; better treatment is oral doxycycline 25 mg PO twice daily for three weeks.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 U/gm: 3.5 gm tubes; *Terramycin*® Ophthalmic Ointment (Pfizer); (Rx)

HUMAN-LABELED PRODUCTS:

Tetracycline HCl Ointment: 10 mg/g in 3.75 g tubes; *Achromycin*® (Storz/Lederle); (Rx)

Tetracycline HCl Suspension: 10 mg/mL in 4 mL btl; *Achromycin*® (Storz/Lederle); (Rx)

Other available ophthalmic antibiotics: Chlortetracycline: *Aureomycin*® (Storz Lederle); Bacitracin (alone); Erythromycin Ointment; Polymyxin B powder for solution; Sodium Sulfacetamide.

ANTIBIOTIC COMBINATIONS

(OPHTHALMIC)

Indications/Pharmacology

These combination products exhibit a broad-spectrum of activity and are considered the first choice for symptomatic treatment of conjunctivitis in dogs and for prophylactic treatment of small animals prior to or after eye surgery. These agents are also used prophylactically for corneal injuries/wounds.

Suggested Dosages/Precautions/Adverse Effects

Usually applied 4 times daily to prevent infection and up to every 30 minutes in established corneal infections. See individual product label information and the information noted previously.

Neomycin has been reported to cause allergic reactions in dogs and cats, particularly after prolonged usage. As noted above, avoid neomycin treatment in cats unless absolutely necessary. Interestingly, anaphylactic reactions in cats have only been associated with neomycin products in ointment form in the absence of cortisone, but not with antibiotic-steroid combination preparations.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; *Mycitracin*® (Upjohn) (**Note:** contains 500 mg bacitracin/gm); *Neobacimyx*® (Schering); *Trioptic-P*® (Pfizer); *Vetropolycin*® (Pitman-Moore); generic; (Rx). Approved for dogs and cats.

Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 U/gm Ophthalmic Ointment: 3.5 gm tubes; *Terramycin*® Ophthalmic Ointment (Pfizer); (OTC). Approved for use in dogs, cats, sheep, cattle, and horses.

Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per mL Ophthalmic Solution: *Optiprime*® (Syntex); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

There are a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (e.g., gramicidin in place of bacitracin in topical solutions-*Neosporin*® Ophthalmic Solution). All these products require a prescription.

ANTIBIOTIC AND CORTICOSTEROID COMBINATIONS

(OPHTHALMIC)

Indications/Pharmacology

There are three basic categories of these products that are routinely used in veterinary medicine; antibiotic combinations with hydrocortisone, antibiotic combinations with dexamethasone, and individual antibiotics (e.g., gentamicin or chloramphenicol) with a steroid.

Antibiotic combinations with hydrocortisone (ointment or solution) are used in dogs and horses for conjunctivitis as nonspecific therapy after ruling out other causes for red painful eyes, including glaucoma and anterior uveitis. They generally are applied 4 times

daily and then on a tapering schedule based on the response to therapy. The hydrocortisone is relatively weak as an antiinflammatory agent and is not effective for intraocular inflammatory disease such as anterior uveitis. The relative penetration and potency of hydrocortisone in these preparations makes them relatively ineffective for immune mediated extraocular disease including scleritis, episcleritis and or nodular granulomatous episclerokeratitis. Anterior uveitis is statistically more common in horses than simple conjunctivitis and the steroid in these agents would not be helpful in improving the clinical signs of immune mediated uveitis.

Antibiotic combinations with dexamethasone are valuable for use in cases of more severe canine or equine conjunctivitis, nonulcerative keratitis and for immune-mediated scleral or corneal conditions such as chronic superficial keratitis (German shepherd pannus), feline eosinophilic keratitis, scleritis, episcleritis and nodular granulomatous episclerokeratitis. For these conditions the antibiotic agent is not necessary but dexamethasone-only products are not always available. These medications are also used in the equine species with equine uveitis because the ointment forms persist on the cornea longer than drops.

Single agent antibiotic (gentamicin) and potent steroid (betamethasone) combination products (e.g., *Gentocin Durafilm*®) are commonly used in veterinary medicine. However, there are few instances in veterinary ophthalmology in which a very potent corticosteroid agent and an aminoglycoside antibiotic are necessary in combination. Simple conjunctivitis in dogs and horses is adequately treated with antibiotic combinations with hydrocortisone. Avoid use of this agent in cats with conjunctivitis for the reasons noted below.

Suggested Dosages/Precautions/Adverse Effects

See individual product label information and the information noted above.

Avoid use of antibiotic/steroid combination agents in cats with conjunctivitis as the most common cause of conjunctivitis in the cat is primary or recurring infection with exposure to, or reactivation of, latent feline herpes virus. Recent research indicates that topical steroids increase the length of the typical course of feline herpes virus related conjunctivitis and/or keratitis and can induce corneal involvement in cases that might otherwise have remained confined to conjunctiva. Corneal sequestration has been noted to occur in cats with herpes virus conjunctivitis after treatment with topical steroids. Recommended treatment for feline herpes virus conjunctivitis is tetracycline ointment *QID* during active disease, as this drug is effective against *Mycoplasma* and *Chlamydia* (**Note:** concurrent systemic treatment with doxycycline will likely be necessary to clear *Chlamydia* organisms from the nasal and/or GI passages in cats as discussed above).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Triple Antibiotic Ointments with Hydrocortisone:

Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units & Hydrocortisone acetate 1% per gram in 3.5 gm tubes; *Neobacimyx H*® (Schering); *Trioptic-S*® (Pfizer); *Vetropolycin HC*® (Pitman-Moore); generic; (Rx). Approved for dogs and cats.

Other Antibiotic/Steroid Ointments:

Neomycin Sulfate 5 mg & Prednisolone 2 mg (0.2%) per gram in 3.5 gram tubes; *Optisone*® (Evsco); (Rx). Approved for use in dogs and cats.

Neomycin Sulfate 5 mg & Isoflupredone acetate 1 mg (0.1%) per gram in 3.5 & 5 gram tubes; *Neo-Predef*® Sterile Ointment (Upjohn); (Rx). Approved for use in horses, cattle, dogs and cats.

Chloramphenicol 1% and Prednisolone acetate 2.5 mg (0.25%) in 3.5 gm tubes; *Chlorasone*® (Evsco) (Rx). Approved for use dogs and cats.

Drops:

Gentamicin Ophthalmic Drops 3 mg/mL & Betamethasone acetate 1 mg/mL in 5 mL btl; *Gentocin Durafilm*® (Schering); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

There are a wide variety of human-labeled ophthalmic antibiotic/steroid combination products available. Some of the more commonly used combinations include:

Ointments:

Bacitracin/Neomycin/Polymyxin B and Hydrocortisone; *Cortisporin*® (BW); (Rx)

Neomycin/Polymyxin B & Dexamethasone; *Maxitrol*® (Alcon); (Rx)

Neomycin and Dexamethasone; *NeoDecadron*® (Merck); (Rx)

Drops:

Neomycin/Polymyxin B and Hydrocortisone; *Cortisporin*® (BW, etc.); (Rx)

Neomycin/Polymyxin B & Dexamethasone; *Maxitrol*® (Alcon); (Rx)

Neomycin and Dexamethasone; *NeoDecadron*® (Merck); (Rx)

Antifungals

Fungal keratitis is a serious corneal disease, most commonly reported in the horse. The species selectivity of this disease is related to the environment of this animal, which is often contaminated with fungal elements. An increased incidence of fungal keratitis in people was directly related to the development of multiple topical steroid agents for treatment of eye diseases. In the horse, many cases of fungal keratitis are noted in association with prior treatment of conjunctival and/or corneal diseases with topical steroid agents. Aspergillus is the most common cause of fungal keratitis in the horse, although there is a great deal of variation in fungal isolates from the cornea depending upon geographical location. Studies in people and anecdotal reports from veterinarians suggest that fungal keratitis due to fusarium organisms are more resistant to therapy than are those caused by aspergillus. Most studies in the equine suggest that about 50% of cases of fungal keratitis in the horse result in perforation of the corneal and enucleation of the eye. Medical and surgical therapy (keratectomy, corneal debridement, and conjunctival grafting) are used to treat such cases with the goals of therapy including arresting infection, mechanical removal of organisms from the cornea, and support of the cornea. All antifungal agents available for use in the equine suffer from poor penetration into the corneal stroma. Conjunctival grafting may further hinder drug penetration as a trade off to improving vascular availability to the cornea and mechanical support. Pathologic specimens from horses with fungal keratitis indicate that fungal organisms, unlike bacterial organisms, have a propensity to multiply deep in the stroma, directly adjacent to Descemet's membrane, making corneal penetration an important issue. Because the prognosis for return of vision and saving the globe in cases of fungal keratitis cases is guarded and because treatment is labor intensive, referral to teaching or other hospitals for 24 hour care and observation is recommended.

AMPHOTERICIN B

(OPHTHALMIC)

(am-foe-ter-i-sin B)

Indications/Pharmacology

Amphotericin B has been used topically and subconjunctivally to treat cases of equine fungal keratitis. Amphotericin B is fungistatic or fungicidal depending on the concentration obtained in body fluids and the susceptibility of the fungus. The drug acts by binding to sterols in the cell membrane of susceptible fungi with a resultant change in membrane permeability allowing leakage of intracellular components. Mammalian cell membranes also contain sterols and it has been suggested that the damage to human cells and fungal cells may share common mechanisms. Amphotericin B has been shown to be effective against the following fungi: *Histoplasma capsulatum*, *Coccidioides immitis*, *Candida* species, *Blastomyces dermatitidis*, *Rhodotorula*, *Cryptococcus neoformans*, *Sporothrix schenckii*, *Mucor mucedo*, and *Aspergillus fumigatus*. While *Candida albicans* is generally quite susceptible to amphotericin B, non-albicans species may be less susceptible. *Pseudallescheria boydii* and *Fusarium* spp. are often resistant to amphotericin B. The major action of amphotericin B is to bind ergosterol in the fungal plasma cell membrane, making the membrane more permeable and resulting in leakage of cell electrolytes and cell death. At high concentrations, amphotericin B is thought to cause oxidative damage to the fungal cell or disruption of fungal cell enzymes.

Suggested Dosages/Precautions/Adverse Effects

Instill 0.2 mL of a 0.15% solution in the eye or the palpebral lavage catheter every 2–6 hours, or 0.25 mL of a 0.5 mg/mL solution subconjunctivally every 48 hours. There are no commercially available amphotericin B ophthalmic products, but the non-liposomal injectable formulation can be reconstituted with sterile water to make sterile solutions suitable for topical or subconjunctival administration. Amphotericin B should not be reconstituted with sodium chloride containing solutions as this encourages degradation of the drug.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Sterile solutions for topical ophthalmic administration or subconjunctival injection may be prepared by reconstituting commercially available amphotericin B injection lyophilized powder and diluting to appropriate concentrations with sterile water for injection. Chemical stability is concentration dependent, but most resulting solutions may be stored for at least 7 days under refrigeration and protected from light.

POVIDONE IODINE

(OPHTHALMIC)

Indications/Pharmacology

Dilute solutions of povidone iodine (1%–5%) have been utilized for chemical debridement of loose epithelium in canine indolent ulcers. 5% povidone iodine has also been used as an antifungal for fungal keratitis, but must be lavaged from the eye within 5 minutes to prevent damage to corneal epithelium. Generally, povidone io-

dine is only used once daily and then rinsed off when used in the eye as an anti-fungal. There has also been a renewed interest in utilizing povidone iodine in treating feline herpes keratitis. Solutions of commercially available 10% povidone iodine are diluted in physiologic saline to concentrations of 0.5–1% and applied 1 drop twice to four times daily for treatment of chronic feline herpes keratitis and may also be used prophylactically for feline herpes-virus (FHV) cats with a history of recurring ulcer.

Suggested Dosages/Precautions/Adverse Effects

Solutions of 1% are applied twice to four times daily for treatment and prophylaxis of feline herpes-virus (FHV) keratitis and for chemical debridement of epithelium for canine indolent ulcers. Solutions of concentration greater than 1% should be lavaged from the eye after no more than 5 minutes to prevent corneal epithelial damage.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Products must be compounded and diluted from the commercially available povidone iodine 10% solutions and diluted to final concentrations of 0.5–1% for antiviral indications and no more than 5% for use as an ophthalmic irrigant.

NATAMYCIN

(na-ta-mye-sin)

Indications/Pharmacology

Natamycin is a semisynthetic polyene antibiotic. Natamycin is poorly water-soluble and will not penetrate the intact corneal epithelium. Natamycin is the only antifungal agent approved for use on the eye and the only commercially available eye drug for treatment of fungal keratitis.

Suggested Dosages/Precautions/Adverse Effects

The product comes as a thick white suspension that complicates the use of subpalpebral lavage apparatus for frequent treatment of the cornea of the horse. This drug will obstruct catheter systems used for medication. It will cause dramatic swelling and pain in the upper eyelid if it leaks out of the tubing into the subcutaneous tissues of the eyelid. Corneal penetration is poor and the medication is very expensive. Fungal keratitis cases are treated aggressively with hourly or bi-hourly treatment the first 1–3 days and gradual reduction in treatment frequency with signs of clinical improvement. Cytology and repeated cultures of the cornea are used to indicate treatment effectiveness. Worsening of the corneal edema and cellular infiltration can be a sign of treatment response. This is thought to be due to antigenic release associated with killing of fungal organisms (like the pulmonary response noted in dogs with institution of antifungal therapy for blastomycosis, etc.). Four to six weeks of treatment is not uncommon for fungal keratitis cases.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Natamycin Ophthalmic Suspension 5%: 15 mL btl; *Natacyn*® (Alcon); (Rx)

MICONAZOLE

(OPHTHALMIC)

(mi-kon-a-zole)

Indications/Pharmacology

Miconazole is a broad spectrum imidazole antifungal agent with some antibacterial activity. Miconazole will penetrate the intact corneal epithelium. Topical miconazole therapy has been a favorite first choice agent for treatment of fungal keratitis in the horse by veterinary ophthalmologists for several years. Miconazole may be delivered by subconjunctival route, but with some local irritation, and topical use is the most commonly employed treatment method.

Suggested Dosages/Precautions/Adverse Effects

Miconazole was formerly available as a 10 mg/mL injectable solution for IV use in humans. It can now only be obtained through s. It is a clear solution readily delivered through subpalpebral lavage apparatus systems. The medication is significantly less expensive compared with natamycin and its corneal penetration is more favorable, although still less than optimal. Treatment is generally delivered hourly or bi-hourly during the first several days of treatment. Once clinical improvement is noted and cytology specimens and repeated cultures indicate eradication of fungal organisms, the treatment frequency is gradually reduced. Most fungal keratitis cases are treated 4–6 weeks.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None suitable for the eye.

All commercially available miconazole topical preparations contain alcohols or other agents that cause corneal damage. It is imperative that a 1% miconazole solution be compounded without alcohols for use on the cornea.

SILVER SULFADIAZINE

(OPHTHALMIC)

(sil-ver sul-fa-dye-a-zeen)

Indications/Pharmacology

Silver sulfadiazine cream is a broad spectrum agent which covers bacteria (gram positive and negative) and fungal agents. It has been used extensively in people suffering from skin burns. It is nontoxic to the skin, conjunctiva and cornea and has been used in the last several years for cases of fungal keratitis. Particularly good results have been noted in cases of superficial keratitis prior to development of advanced disease. Clinical response is better when used early in the course of the disease. Treatment with silver sulfadiazine is considered non-conventional in people. It is gaining in popularity in the treatment of equine fungal keratitis by veterinary ophthalmologists. For medico-legal reasons, in very expensive horses in which litigation may be an issue, treatment with more conventional therapy (natamycin) may be indicated first, or consideration can be given to signed consent regarding treatment with silver sulfadiazine. The initial response to this drug has been promising, however.

Suggested Dosages/Precautions/Adverse Effects

The commercially available product is a cream, but can be delivered into the conjunctival sac using a tuberculin syringe, without the needle. A typical treatment dose is 0.2 mL drawn into a syringe. It will not pass through standard sized subpalpebral lavage catheters, although it may be administered through large medication administration systems using red rubber feeding tubes passed through the lid, with variable results getting the medication to pass through the tube. It is probably best applied manually. The cream sticks well to the cornea that probably improves effectiveness, similar to natamycin, as compared to miconazole. Treatment regimes are similar to the other antifungal agents with very frequent applications necessary during the early phases of the treatment and reduction in therapy based upon clinical response. Daily debridement of the necrotic corneal stroma and epithelium will improve penetration of the drug and the clinical response.

The medication is inexpensive and is available from any pharmacy, but it is not labeled for use in eyes. The label (package insert) specifically states “not to be used in eyes” so liability for use in eyes rests solely with the prescribing veterinarian and some pharmacists may be unwilling to dispense this medication for ophthalmic use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Silver Sulfadiazine Topical (**not an ophthalmic product**): 10 mg per gram in a water miscible cream base; 20, 50, 400, and 1000 g containers; *Silvadene*® (Marion); *Flint SSD*® (Flint); (Rx). Preferably dispensed aseptically in single use sterile tuberculin syringes for application to the conjunctival sac.

ITRACONAZOLE

(OPHTHALMIC)

(i-tra-koe-na-zole)

Indications/Pharmacology

Itraconazole is a broad spectrum synthetic antifungal agent effective against a wide range of filamentous fungi, dimorphic fungi, and yeasts. It is the most popular systemic antifungal agent for treatment of blastomycosis related and other systemic fungal infections in dogs and people. Itraconazole specifically targets oxidative enzymes of fungal organisms thereby increasing efficacy while lowering toxicity. Itraconazole prepared as a 1% ointment in 30% dimethylsulfoxide (DMSO) is well tolerated in horses with keratomycosis with reported good results. Itraconazole is relatively insoluble in water and must be diluted in DMSO to achieve solution. Itraconazole 1% suspensions in a vehicle of 30% DMSO and 70% artificial tears have also been used successfully to treat fungal keratitis in horses. It is important to note that the DMSO may be topically irritating to many horses. The fungal species most commonly isolated from cases of equine keratomycosis and their particular sensitivity to specific antifungal agents varies greatly by geography in the United States. In vitro sensitivity testing can be done at select laboratories on fungal isolates from the equine eye but this information generally takes several weeks to become available. Because of these considerations, the selection of a particular antifungal drug for an individual case is largely based on local clinical experience and impressions.

Suggested Doses/Precautions/Adverse Effects

Compounded itraconazole/DMSO preparation is applied to the cornea frequently in horses with confirmed keratomycosis. Treatment every 2–3 hours would not be uncommon initially with tapering of the treatment based on clinical response. Individuals treating horses need to use routine precautions (gloves) while handling this medication to minimize any skin uptake enhanced by the DMSO solvent.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Compounded product. Must be obtained from a compounding pharmacy as a 1% suspension or ointment.

VORICONAZOLE

(vor-i-kon-a-zole)

Indications/Pharmacology

Voriconazole has been used clinically for the treatment of equine fungal keratitis. Voriconazole is a triazole antifungal agent. The primary mode of action of voriconazole is the inhibition of fungal cytochrome P-450-mediated 14 alpha-lanosterol demethylation, an essential step in fungal ergosterol biosynthesis. The accumulation of 14 alpha-methyl sterols correlates with the subsequent loss of ergosterol in the fungal cell wall and may be responsible for the antifungal activity of voriconazole. Voriconazole has been shown to be more selective for fungal cytochrome P-450 enzymes than for various mammalian cytochrome P-450 enzyme systems. Voriconazole has demonstrated *in vitro* activity against *Aspergillus* (*A. fumigatus*, *A. flavus*, *A. niger* and *A. terreus*), *Candida* (*C. albicans*, *C. glabrata*, *C. krusei*, *C. parapsilosis* and *C. tropicalis*), *Scedosporium apiospermum* and *Fusarium* spp., including *Fusarium solani*. Voriconazole drug resistance development has not been adequately studied *in vitro* against *Candida*, *Aspergillus*, *Scedosporium* and *Fusarium* species. The frequency of drug resistance development for the various fungi for which this drug is indicated is not known. Fungal isolates exhibiting reduced susceptibility to fluconazole or itraconazole may also show reduced susceptibility to voriconazole, suggesting cross-resistance can occur among these azoles. The relevance of cross-resistance and clinical outcome has not been fully characterized. Clinical cases where azole cross-resistance is demonstrated may require alternative antifungal therapy. There are no approved ophthalmic formulations of voriconazole, however, a suitable solution for ophthalmic administration can be prepared by utilizing the approved voriconazole injectable product.

Suggested Dosages/Precautions/Adverse Effects

0.2 mL in the eye or palpebral lavage catheter every 2–4 hours. Voriconazole is contraindicated in patients with known hypersensitivity to voriconazole or its excipients. There is no information regarding cross-sensitivity between voriconazole and other azole antifungal agents. Caution should be used when prescribing voriconazole to patients with hypersensitivity to other azoles. Voriconazole treatment-related visual disturbances are common in humans. In therapeutic trials, approximately 21% of patients experienced abnormal vision, color vision change and/or photophobia. The visual disturbances were generally mild and rarely resulted in discontinuation. Visual disturbances may be associated with higher plasma concentrations and/or doses. Since topical administration of voriconazole has not been evaluated in humans, it is

not known if this adverse event occurs with topical administration. The mechanism of action of the visual disturbance is unknown, although the site of action is most likely to be within the retina. In a study in healthy volunteers investigating the effect of 28-day treatment with voriconazole on retinal function, voriconazole caused a decrease in the electroretinogram (ERG) waveform amplitude, a decrease in the visual field, and an alteration in color perception. The ERG measures electrical currents in the retina. The effects were noted early in administration of voriconazole and continued through the course of study drug dosing. Fourteen days after end of dosing, ERG, visual fields and color perception returned to normal. Dermatological reactions are also common in human patients treated with voriconazole. The mechanism underlying these dermatologic adverse events remains unknown. In clinical trials, rashes considered related to therapy were reported by 7% (110/1655) of voriconazole-treated patients. The majority of rashes were of mild to moderate severity. Cases of photosensitivity reactions appear to be more likely to occur with long-term treatment. Human patients have rarely developed serious cutaneous reactions, including Stevens-Johnson syndrome, toxic epidermal necrolysis and erythema multiforme during treatment with VFEND. If patients develop a rash, they should be monitored closely and consideration given to discontinuation of VFEND. It is recommended that patients avoid strong, direct sunlight during VFEND therapy. The extent of these adverse drug reactions in animals is unknown at this time.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

There are no commercially available ophthalmic dosage forms of voriconazole. A suitable solution for ophthalmic administration may be prepared by aseptically adding 19 mL of sterile water for injection to a 200 mg vial of VFend® injection to result in a sterile 1% solution. Resulting solution should be stored under refrigeration and discarded 28 days after reconstitution.

Antivirals (Ophthalmic)

Antiviral drugs are used most commonly in clinical practice for the treatment of feline ocular herpes virus infections. Simple acute conjunctivitis is best managed with symptomatic antibiotic therapy alone (*i.e.*, tetracycline treatment or systemic doxycycline treatment). The development of concurrent corneal disease, however, indicates that consideration should be given to the use of antiviral drugs. Persistent cases of conjunctivitis in the cat due to feline herpes virus infection may also benefit from treatment with topical antiviral drugs. Although *in vitro* studies indicate that trifluridine is the most effective agent against feline herpes virus, idoxuridine is a less irritating, more economical alternative. In general, all antivirals are virustatic (not cidal) and require application every 2 hours for the first 24 hours followed by 5–6 times daily treatment thereafter. While this appendix focuses mostly on topical ophthalmic therapies, it is important to note that studies support use of L-lysine at 500 mg orally twice daily in cats to prevent or reduce the severity of feline herpes virus ocular infections through disruption of viral replication.

TRIFLURIDINE (TRIFLUOROTHYIMIDINE)

(trye-flure-i-deen)

Indications/Pharmacology

Trifluridine (trifluorothymidine; *Viroptic*®) is a pyrimidine nucleoside analog. It is structurally related to 2-deoxythymidine, the natural precursor of DNA synthesis. Trifluridine is poorly absorbed by the cornea and is virostatic. *Viroptic*® interrupts viral replication by substituting “nonsense” pyrimidine analogues. For this reason, a competent surface immunity is necessary to resolve ocular disease, with or without antiviral therapy. A recent *in vitro* study in which several strains of feline herpes virus were collected from the United States and were used to infect kidney epithelial cells showed that trifluridine was more effective at lower concentrations compared with several other agents. For this reason, trifluridine was the first choice drug employed in the treatment of feline herpes virus ocular disease for many years. Because of the topical toxicity associated with use of trifluridine in cats, its popularity has diminished greatly. In many milder cases, the irritation associated with topical trifluridine is more intense than the inflammation induced by viral infection. Antiviral agents have also been used in the treatment of superficial punctate keratitis in the horse, thought to be associated with equine herpes virus-2 (EHV-2) infection of the cornea.

Suggested Dosages/Precautions/Adverse Effects

Trifluridine must be applied very frequently. Many veterinary ophthalmologists recommend treatment every 2 hours (waking hours) during the first 2 days of therapy to establish effective corneal drug levels. After this time, treatment 4–6 times daily is indicated. Because trifluridine is virostatic and not viricidal, treatment 1 week beyond the resolution of clinical signs is recommended, to prevent a rebound effect associated with poor surface immunity in combination with residual active viral agents. However, a maximum supply of 3 weeks medication should initially be dispensed as trifluridine is a corneal toxin and can retard corneal epithelial healing. Additionally, if cats do not respond favorably to trifluridine therapy within three weeks, they are not likely to respond with longer durations of therapy. If no improvement is noted in three weeks, trifluridine (or any antiviral) should be discontinued for a rest period and then a different antiviral initiated.

Anecdotally, improvement with antiviral agents is noted in about 50% of cats in which the treatment is employed. In some cats the ocular disease persists despite treatment with antiviral agents. It is not certain if these are truly cases of feline herpes virus infection or other disease as the confirmation of feline herpes virus infection is exceedingly difficult in practice, (except in the acute disease with respiratory and ocular involvement, because of the logistics of viral isolation tests for doctors in clinical practice (usually only available at major institutions or referral centers) and because of the high degree of false negatives with herpes virus FA tests and with available polymerase chain reaction (DNA amplification) technology). Chronic conjunctivitis in the cat seems to be the most resistant to treatment with antiviral agents. Conjunctival and lid margin irritation are commonly reported with trifluridine use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Trifluridine Ophthalmic Solution: 1% in 7.5 mL btl; *Viroptic*® (Monarch); (Rx)

IDOXURIDINE

(eye-dox-yoor-i-deen)

Indications/Pharmacology

Idoxuridine (IDU) is chemically similar to thymidine and its substitution into viral DNA causes misreading of the viral genetic code thereby inhibiting viral replication. Like trifluridine, IDU is considered virostatic rather than viricidal. IDU was found to be second to trifluridine in efficacy *in vitro* against common strains of feline herpes virus growing in kidney epithelial cells. IDU is extremely well tolerated in cats and this feature alone makes it the most popular antiviral currently available for use in cats with presumed or established feline herpes virus infection. Although trifluridine was shown to be more effective *in vitro*, the topical irritation it induces in cats frequently negates any beneficial effect that might be noted clinically. Stinging upon application is a rare feature with IDU/artificial tear preparations.

Suggested Doses/Precautions/Adverse Effects

IDU, like trifluridine, penetrates poorly into the cornea (except in instances of ulceration) and conjunctiva and therefore must initially be applied frequently. Most treatment protocols involve application every two to three hours during waking hours the first two days of acute infection, followed by four to five times daily treatment continued a week beyond resolution of clinical signs. IDU has been particularly useful in the management of cats with chronic feline herpes virus conjunctivitis. These cats maintain low-grade viral activity in the cornea, occasionally showing accelerated viral growth with secondary corneal involvement (ulceration/sequestrum). With chronic treatment, the conjunctivitis component is rarely suppressed in total, but usually the corneal disease, which is the most problematic from a vision and comfort standpoint, can be controlled.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Formerly approved as *Stoxil*[®] and *Herplex*[®]; must be obtained from compounding pharmacies as a 0.1% ophthalmic solution or a 0.5% ophthalmic ointment.

INTERFERON ALPHA

(TOPICAL)

(in-ter-feer-on al-fa)

Indications/Pharmacology

Interferon alpha-2B is thought to stimulate local immunity against viral infection and has been advocated as an adjunct therapy for treatment of feline herpes keratitis. A German study has also recently reported that topical interferon alpha may speed the resolution of corneal sequestrum without surgery.

Suggested Dosages/Precautions/Adverse Effects

It has been used both systemically (30 IU PO q24h) and/or topically (30 – 50 IU/mL in artificial tears in both eyes 3–5 times daily) for refractory cases of feline herpes keratitis.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

The human interferon alpha-2B injection (*Intron-A*[®]—Schering) is diluted to a final concentration of 30 – 50 IU/mL in saline or artificial tears and administered orally or topically respectively.

ACYCLOVIR VALACYCLOVIR FAMCICLOVIR GANCICLOVIR CIDOFOVIR PENCICLOVIR

Indications/Pharmacology

Ophthalmic acyclovir is not yet available in the US, but is available in other countries. It is being compounded for use in the US. Systemic anti-retroviral agents have been tried in cats with persistent herpes keratitis, but myelosuppression and nephrotoxicity following systemic use is a serious risk with acyclovir and valacyclovir. Acyclovir should only be used systemically as a last resort and CBC should be monitored weekly in cats receiving this drug. Valacyclovir apparently has no effect on feline herpes replication and should be avoided completely due to fatal myeloid dysplasia. Anecdotal response to famciclovir (metabolized to penciclovir in cats) has been discussed, but no scientific evidence is available to substantiate its effectiveness against FHV or its safety in cats. As other agents in this drug class are myelosuppressive, extreme caution is recommended regarding famciclovir therapy in cats. Topically administered cidofovir 0.5% solutions have recently been shown to reduce the severity and duration of FHV-1 infections. The *in vitro* efficacy of commonly available antiviral agents for FHV-1 has been studied and is as follows: trifluridine > ganciclovir = idoxuridine = cidofovir = penciclovir = vidarabine > acyclovir >> foscarnet.

Suggested Doses/Precautions/Adverse Effects

Cidofovir 0.5% topical solution, 1 drop in each eye twice daily. Until further data is available, systemic use of these agents is not recommended in cats. Myelosuppression, often fatal, and nephrotoxicity are likely when using these agents systemically in cats. Doses of acyclovir at 100 – 200 mg per cat orally BID-TID have been used with anecdotal reports of success but weekly monitoring of CBC is imperative with use of these agents systemically. Topical acyclovir ophthalmic ointment should be used with caution in cats as they are likely to groom off medication and experience systemic adverse effects.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Sterile solutions of cidofovir suitable for ophthalmic administration may be prepared by diluting the commercially available injection to a final concentration of 5 mg/mL using 1% carboxymethylcellulose solutions. Acyclovir 3% ophthalmic ointment may be obtained from compounding pharmacies.

Keratoconjunctivitis Sicca

Keratoconjunctivitis sicca (KCS) is a common ocular disorder in dogs. Recent research efforts indicate that KCS in dogs is an immune mediated disease. It is similar to Sjogren's Syndrome in humans except we do not recognize a connective tissue disorder in the dog compared to this disease in people (man-dry eye, dry mouth, and connective tissue disorder like rheumatoid arthritis; dogs just dry eye). Immune mediated lacrimal adenitis can result in complete destruction of tear producing glands in dogs. Glandular fibrosis produces absolute sicca and these cases may be better managed with a parotid duct transposition surgery because there may be little remaining gland tissue to treat.

CYCLOSPORINE

(OPHTHALMIC)

(syé-kloe-spor-éen)

Indications/Pharmacology

Cyclosporine is a polypeptide agent first isolated from a fungus. The agent interferes with interleukin synthesis by T lymphocytes and in so doing has been employed extensively in people following major organ transplantation to prevent immune rejection. Cyclosporine is extremely hydrophobic and was originally compounded by pharmacists in virgin olive oil or purified corn oil for the topical application to dogs with keratoconjunctivitis sicca. Topical cyclosporine is now commercially available as a 0.2% ointment (*Optimmune*®-Schering). The mechanism of action of cyclosporine in the treatment of keratoconjunctivitis sicca is still not fully understood, although it has been employed in the treatment of KCS in dogs for several years. It stimulates increased tear production in normal dogs and for this reason it is thought to have a direct stimulatory effect on the tear gland. It may do this acting as a prolactin analog, fitting onto lacrimal prolactin receptors. Its interleukin blocking effects likely are the major mechanism of action. Halting local inflammatory mediator production appears to arrest self perpetuating lacrimal adenitis resulting in resumption of normal or improved tear production after several weeks of therapy, however, cessation of therapy results in return of symptoms in a matter of days. Cyclosporine in the cornea appears to have the ability to lessen granulation and pigment development. This property appears to be unrelated to its tear producing ability.

The reported success rate of alleviating the signs of KCS in dogs with treatment with cyclosporine is 75–85%. Some studies indicate that the higher the Schirmer value prior to starting therapy, the more likely that the dog will be well managed with cyclosporine alone. Absolute sicca may be associated with extensive fibrosis of the tear glands, leaving little tissue for stimulation or repair.

Cyclosporine is effective in the management of German Shepherd Pannus or chronic superficial keratitis in the dog. This condition is an immune disease of the cornea and likely is interleukin mediated. Cyclosporine may be preferred for the treatment of pannus because of the lack of systemic side effects noted in dogs with chronic topical administration of cyclosporine. Chronic topical corticosteroid treatment is associated with biochemical changes in the blood of large and small dogs.

Cyclosporine has been tried in the management of the rare case of keratoconjunctivitis sicca in the cat. Dry eye in cats is usually associated with herpes virus destruction of lacrimal epithelial cells and or stenosis of the ductules or openings of the ductules due

to chronic viral conjunctivitis. Preliminary results have not been promising. Topical cyclosporine often aggravates ophthalmic herpes virus infections in people. Cyclosporine has not shown promising effects in the management of feline eosinophilic keratitis, a condition now thought to be related to chronic stromal herpes virus infection in cats.

Suggested Dosages/Precautions/Adverse Effects

Cyclosporine is initiated generally as the first course of therapy for confirmed dry eye cases in the dog. The topical half-life of cyclosporine is about 8 hours and most canine cases of KCS are managed with twice daily therapy with 0.2% ointment (*Optimmune*®). Three times a day therapy has been employed during the initial phases of treatment in more difficult or slow responding cases. For unknown reasons (reversal of lacrimal adenitis > reorganization of lacrimal epithelial cell function > formation of secretory granules > tear production) 3–8 weeks of therapy are necessary before a dramatic increase in the Schirmer tear test becomes evident. Patients are generally maintained for life on cyclosporine ophthalmic once or twice daily depending on the response. Discontinuation of therapy is usually associated with the return of clinical signs of KCS within a few days. Reinstitution of therapy, at this time, is usually associated with an almost immediate return of tear production (versus the initial lag phase noted). This likely is related to the degree of inflammatory disease noted with short discontinuation of therapy versus that present initially, prior to the diagnosis of KCS.

If tear production is very low, cyclosporine is often used in combination with artificial tears during the initial phases of therapy. Once tear production is improved, artificial tears can generally be removed completely or their frequency reduced in the treatment plan. After treatment is initiated, reevaluation of tear production in one month is recommended. If ulcerative keratitis complicates keratoconjunctivitis sicca in the dog, more frequent evaluation is necessary. Cyclosporine, although an immunomodulating agent, is considered safe in the face of ulcerative keratitis, with concurrent antibiotic therapy. Caution is advised, however.

When cyclosporine is delivered topically, no systemic toxicity has been noted in dogs given this drug chronically. This is probably associated with the poor absorption of this drug across the GI tract and because it is delivered to the eye at very low concentrations which even if 100% absorbed, when divided over the body weight of the dog is well below even the therapeutic dose. Advanced detection methods have made it possible to measure trace levels of cyclosporine in the blood of dogs being topically treated for dry eye. The clinical implication of this finding is uncertain at this time.

Dosage Forms/Regulatory Status

Optimmune® ointment is the approved formulation of topical cyclosporine for the management of dry eye in dogs. Compounding of topical cyclosporine drops was popular before the introduction, approval, and marketing of *Optimmune*® ointment. Clinicians persistently using compounded formulations of cyclosporine eye drops may be outside of expected ethical and legal standards of practice except under very specific situations. The use of commercially available ophthalmic products instead of compounded medications is highly recommended. *Optimmune*® is first applied 2 or 3 times daily and frequency of daily application is adjusted based on clinical response.

VETERINARY-LABELED PRODUCTS:

Cyclosporine Ophthalmic Ointment 0.2%; *Optimmune*® (Schering-Plough); (Rx)

HUMAN-LABELED PRODUCTS:

Cyclosporine 0.05% Ophthalmic Emulsion; *Restasis*® (Allergan). **Note:** the concentration of this product has not been shown to in-

crease tear production in dogs. Patients failing to respond to the veterinary approved ophthalmic ointment may respond to compounded cyclosporine 1% ophthalmic solution or tacrolimus 0.03% ophthalmic solution.

TACROLIMUS

(OPHTHALMIC)

(ta-kroe-li-mus)

Indications/Pharmacology

Tacrolimus has recently been studied at the University of Tennessee College of Veterinary Medicine where investigators found it equally effective as cyclosporine and effective for cyclosporine-resistant cases of KCS. It exerts its effects through a mechanism similar to that of cyclosporine, however exact mechanisms of action in causing tear production are still being determined.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None appropriate for the eye. At the time of publication, Fujisawa, Inc. has granted exclusive rights to Sucampo, Inc. to study, develop, and market an ophthalmic tacrolimus formulation for use in KCS. **Note:** *Protopik*[®] topical ointment is a topical tacrolimus formulated with propylene carbonate that is known to deplete cholinesterase and to be an ophthalmic irritant and should not be used in the eye. Tacrolimus 0.01–0.03% solutions and ointments should be prescribed through a compounding pharmacy until a suitable commercially available product are available.

Artificial Tear Products/ Ocular Lubricants

ARTIFICIAL TEARS/ OCULAR LUBRICANTS

Indications/Pharmacology

Artificial tear solutions are aqueous isotonic, pH buffered viscous solutions that serve as a lubricant for dry eyes and associated eye irritation due to dry eye syndromes. They are often useful adjuncts in keratoconjunctivitis sicca in dogs early in cyclosporine therapy.

Ocular lubricants are white petrolatum-based products that serve to lubricate and protect eyes. They are particularly useful during anesthetic procedures where animals' eyes may remain open and during which time tear production is dramatically reduced.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

There are a plethora of products available with a variety of formulations and trade names. All are OTC. Some commonly known products include:

Artificial Tear Products (Methylcellulose-based): *Adsorbotear*[®] (Alcon); *Comfort Tears*[®] (Pilkington Barnes Hind); *GenTeal*[®] (Ciba Vision); *Isopto-Tears*[®] (Alcon); *Tears Naturale*[®] (Alcon); *Lacril*[®] (Allergan)

Artificial Tear Products (Polyvinyl Alcohol-based): *Hypotears*[®] (Iolab); *Liquifilm Tears*[®] (Allergan); *Tears Plus*[®] (Allergan)

Artificial Tear Products (Glycerin-based): *Dry Eye Therapy*[®] (Bausch & Lomb); *Eye Lube A*[®] (Optopics)

Ocular Lubricants (Petrolatum-based): *Lacri-Lube*[®] S.O.P. (Allergan); *Akwa Tears*[®] (Akorn)

OPHTHALMIC IRRIGANTS

Indications/Pharmacology

Sterile isotonic solutions are used for flushing the nasolacrimal system and for removing debris from the eye. They are also used to remove excess stain after diagnostic staining of the cornea. Sterile lactated Ringer's solution (LRS) is well tolerated by the surface of the eye as is a balanced salt solution (BSS). Extraocular irrigating solutions may contain preservatives. Intraocular irrigating solutions (used during surgical procedures) do not contain preservatives and also contain electrolytes that are required for normal cell function.

Suggested Dosages/Precautions/Adverse Effects

Extraocular: Use to flush eye as necessary; control rate of flow by exerting pressure on bottle. Intraocular: Refer to both established practices for each surgical procedure as well as the specific manufacturers' recommendations.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Eye Rinse[®] (Butler); (OTC): Contains: water, boric acid, zinc sulfate, glycerin, camphor. **Note:** This product is not labeled for use as an irrigant per se, but as an aid in cleaning the eye and removing eye stains.

HUMAN-LABELED PRODUCTS:

Common trade name products for extraocular irrigation: *AK-Rinse*[®] (Akorn), *Blinx*[®] (Pilkington Barnes Hind), *Collyrium for Fresh Eyes Eye Wash*[®] (Wyeth-Ayerst), *Dacriose*[®] (Iolab), *Eye Irrigating Solution*[®] (Rugby), *Eye-Stream*[®] (Alcon), *Eye Wash*[®] (several manufacturers), *Eye Irrigating Wash*[®] (Roberts Hauck), *Irrigate Eye Wash*[®] (Optopics), *Optigene*[®] (Pfeiffer), *Star-Optic Eye Wash*[®] (Stellar), *Visual-Eyes*[®] (Optopics). All are OTC.

Common trade name products for intraocular irrigation: **Note:** Most of these products contain Balanced Salt Solution (BSS) = NaCl 0.64%, KCl 0.075%, CaCl₂•2H₂O 0.048%, MgCl₂•6H₂O 0.03%, Na acetate trihydrate 0.39%, sodium citrate dihydrate 0.17%, sodium hydroxide and/or hydrochloric acid to adjust pH, and water: Balanced Salt Solution (various manufacturers), *BSS*[®] (Alcon), *Iocare Balanced Salt Solution*[®] (Iolab); All are Rx.

BSS + solutions that also contain dextrose, glutathione, bicarbonate, phosphate are also available as: *BSS Plus*® (Alcon) and *AMO Endosol Extra*® (Allergan); All are Rx.

Topical Hyperosmotic Agents

POLYSULFONATED GLYCOSAMINOGLYCAN (OPHTHALMIC)

Indications/Pharmacology

Polysulfated glycosaminoglycan (PSGAG) *Adequan*® (Luitpold) inhibits a number of enzymes (lysozyme, hyaluronidase, and serine proteases), decreases prostaglandin E₂ synthesis, reduces production of toxic superoxide radicals, and increases synthesis of collagen proteoglycans and hyaluronic acid. Thus polysulfated glycosaminoglycan, originally developed for use in degenerative osteoarthritis cases, has intriguing properties suggesting usefulness in corneal ulcer management. It has anecdotally been effective in promoting healing of indolent corneal ulcers in dogs but no studies in dogs have been published to date. A Brazilian study reported that when using a 5% PSGAG formulation was applied to indolent ulcers of horses, that 86% of eyes treated were considered healed within 3 weeks of initiation of therapy.

Fibronectin and epidermal growth factors have also been applied in treating indolent ulcers but scientific studies remain to be published regarding efficacy. At the time of publication, surgical keratectomy remains the most reliable treatment for indolent ulcers.

Suggested Dosages/Precautions/Adverse Effects

1 drop of a 5% PSGAG solution in artificial tears applied to the affected eye(s) three times daily.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None, however the veterinary approved *Adequan*® injection may be diluted 1:1 with sterile artificial tears to produce a 5% PSGAG solution.

HUMAN-LABELED PRODUCTS: None.

HYPERTONIC SODIUM CHLORIDE (OPHTHALMIC)

Indications/Pharmacology

The stroma of the cornea is the middle layer located between the outer epithelial layer on the surface of the eye and the inner single epithelial layer lining the cornea, called the corneal endothelium. The stroma consists of highly organized collagen bundles and a few keratocytes (fibroblasts). The spacing of the collagen bundles is critical to absolute clarity of the cornea. The spacing of these bundles is disturbed when fluid enters the stroma. Surrounded by water to the exterior (tears) and on the interior (aqueous humor) the relative dehydration of the stroma is maintained by an active ATP-dependent pump mechanism in the corneal endothelial cells. Degeneration of the corneal endothelium is a relatively common eye problem in older dogs and is a known genetic condition in Boston Terrier and Chihuahua dogs. Fluid continuously seeps into the corneal stroma via the tear film and through aqueous humor

passing between corneal endothelial cells. When the endothelial pumping capacity deteriorates, fluid retention in the stroma causes two problems. Visual impairment can eventually develop. The other common complication is the development of corneal ulcers. Edema fluid retained in the cornea pools into pockets called bullae which progressively migrate to the surface of the cornea, eventually draining through and disrupting the surface epithelium. This results in very slow healing and painful corneal erosions in dogs (type II refractory ulcers). Hyperosmotic agents applied 2–3 times daily help to prevent recurrence of bullae and subsequent corneal ulcers *after* the erosions have healed. Because osmotic agents require an intact epithelial barrier in which to induce a pressure gradient (5% NaCl commercial preparation versus 0.9% NaCl body fluids), they are not effective with respect to healing of stubborn corneal ulcers when present. They simply help to prevent re-ulceration once an intact epithelial barrier has been established. It may be said that these agents simply aggravate irritation already present when used in the face of ulcerative keratitis.

Suggested Dosages/Precautions/Adverse Effects

Muro 128 (5% NaCl) eye drops or ointment are applied two to three times daily on an indefinite basis to the surface of eyes with corneal endothelial degeneration to prevent corneal ulceration. In the event of corneal ulceration, treatment is discontinued and substituted for antibiotic and mydriatic treatment in addition to procedures to promote healing of refractory type corneal ulcers. Muro 128 eye drops are available at a 2% and 5% concentration. The Muro 128 ointment is available at a 5% concentration. Because of limited contact time with eye drops, the 2% solution would not be considered for use in animals. Because of prolonged contact time associated with ointments, the 5% Muro 128 ointment is probably the best of the available products for use in animals.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sodium Chloride 5% Ophthalmic Solution in 15 mL btl; *Adisorb-nac*® (Alcon), *Muro 128*® (Bausch & Lomb), *AK-NaCl*® (Akorn), *Muroptic-5*® (Optopics); (OTC)

Sodium Chloride 5% Ophthalmic Ointment in 15 mL btl; *Muro 128*® (Bausch & Lomb), *AK-NaCl*® (Akorn); (OTC)

Viscoelastic Substances

Viscoelastic substances are vital to ocular surgery, minimizing loss of fluid from the anterior chamber while maintaining intraocular space during surgical procedures. The purity and integrity of viscoelastics ensure tissue protection during and after surgery. Viscoelastics generally fall into two categories — cohesives, that tend to stick together, and dispersives, which are more likely to diffuse out into the anterior chamber. Cohesives, in general, create and maintain space very well in the anterior chamber and help stabilize tissue. Such viscoelastics are easily washed away at the end of the case, but are also, unfortunately, all too easily removed during phacoemulsification. Dispersives, that have lower viscosity, remain in the eye more readily, making them well-suited for difficult cases. They are also excellent for various maneuvers, such as retrieving a lost lens fragment, attempting to viscoelevate cortex, or partitioning away a small piece that continues to get caught on the phacoemulsifier tip. Ophthalmic surgeons should be familiar with the advantages and disadvantages of several viscoelastics and real-

ize the limitations encountered if the surgeon chooses to rely on a single viscoelastic. Veterinary ophthalmologist loyalty to brands of viscoelastics is well-earned as newcomer products to this field have frequently resulted in surgical disasters.

Viscoelastics are also vital to tear replacement.

HYALURONIC ACID

(hye-a-loo-ron-ik as-id)

Indications/Pharmacology

Hyaluronic acid is a natural complex sugar of the glycosaminoglycan family and is a long-chain polymer containing repeating disaccharide units of Na-glucuronate-N-acetylglucosamine. Hyaluronic acid is indicated for use as a surgical aid in cataract extraction (intra- and extracapsular), IOL implantation, corneal transplant, glaucoma filtration and retinal attachment surgery. In surgical procedures in the anterior segment of the eye, instillation of hyaluronic acid serves to maintain a deep anterior chamber within corneal endothelium and other surrounding tissues. Furthermore, its viscoelasticity helps to push back the vitreous face and prevent formation of a postoperative flat chamber. In posterior segment surgery hyaluronic acid serves as a surgical aid to gently separate, maneuver and hold tissues. Hyaluronic acid creates a clear field of vision thereby facilitating intra- and post-operative inspection of the retina and photocoagulation.

Suggested Dosages/Precautions/Adverse Effects

A sufficient amount of hyaluronic acid (generally 10% concentration) is slowly and carefully introduced (using a cannula or needle into the anterior chamber. Injection of hyaluronic acid can be performed either before or after delivery of the lens. Injection prior to lens delivery will, however, have the additional advantage of protecting the corneal endothelium from possible damage arising from the removal of the cataractous lens. Hyaluronic acid may also be used to coat surgical instruments and the IOL prior to insertion. Additional hyaluronic acid can be injected during surgery to replace any hyaluronic acid lost during surgical manipulation. Topical solutions of hyaluronic acid are also used to provide a viscoelastic shield to the cornea and provide prolonged relief from ocular surface discomfort.

Cytotoxic Ophthalmic Agents

CISPLATIN BEADS

(sis-pla-tin)

Indications/Pharmacology

Cisplatin 1.6 mg biodegradable beads are used for intralesional chemotherapy in various cutaneous neoplasia including squamous cell

carcinoma and sarcoids in equine patients. A recent retrospective case series study demonstrated that implantation of cisplatin beads into cutaneous neoplasia was an effective method of treatment for these tumors. Implantation of commercially available beads is less time consuming and safer than intralesional injection of cytotoxic agents suspended in fixed oils.

Dosage Forms/Regulatory Status

VETERINARY APPROVED PRODUCTS:

Matrix III Cisplatin Beads: 1.6 mg per 3 mm bead; 3 beads per packet; (Royer Biomedical, Inc.), (Rx)

HUMAN APPROVED PRODUCTS: None

5-FLUOROURACIL

(flure-oh-yoor-a-sil)

Indications/Pharmacology/Suggested Dosage

5-fluorouracil is a potent cytotoxic chemotherapeutic agent used for the topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

1% solution applied to the affected eye three times daily.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Must be compounded from the injectable product by an appropriately trained compounding pharmacist in a biological safety cabinet approved for preparation of cytotoxic agents

MITOMYCIN-C

(mye-toe-mye-sin)

Indications/Pharmacology

Mitomycin C is a potent cytotoxic chemotherapeutic agent used for topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

Suggested Doses/Precautions

0.4% solution applied initially followed by 0.04% solution applied topically three times daily for 21 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded from the injectable product by an appropriately trained compounding pharmacist in a biological safety cabinet approved for preparation of cytotoxic agents.

Sympathomimetics

HYDROXYAMPHETAMINE

(hye-drox-ee-am-fe-ta-meen)

Indications/Pharmacology

Hydroxyamphetamine is an indirectly acting sympathomimetic which is used to diagnose Cranial Nerve III denervation syndromes such as Horner's Syndrome. Hydroxyamphetamine stimulates release of norepinephrine from postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denervated neurons.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately trained compounding pharmacist.

COCAINE

(OPHTHALMIC)

(koe-kane)

Indications/Pharmacology

Cocaine is an indirectly acting sympathomimetic which is used to diagnose Cranial Nerve III denervation syndromes such as Horner's Syndrome. Cocaine prevents reuptake of norepinephrine into postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denervated neurons.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately trained compounding pharmacist.

Anticollagenase Agents

ACETYL CYSTEINE

(a-se-teel-sis-teen)

Indications/Pharmacology

Acetylcysteine is a mucolytic agent which is also used to stop the melting effect of collagenases and proteases on the cornea. Acetylcysteine is useful in halting melting through inhibition of metalloproteinases, but is not felt to be useful for melting caused by infectious agents.

Suggested Dosages/Precautions/Adverse Effects

Acetylcysteine 5% solution is dosed 1 drop in the affected eye every 1–2 hours for the first 24 hours and then 3–4 times daily for the next 7–10 days. Acetylcysteine solutions are diluted with artificial tears to a final concentration of 5% prior to administration as commercially available solutions of 10% and 20% are topically irritating. Acetylcysteine possesses a foul, sulfur-like smell and owners should be informed that this foul odor does not indicate drug deterioration. Acetylcysteine is unstable at room temperature and solutions should be refrigerated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None; *Mucomyst*® 10% and 20% solution for inhalation may be used to compound a 5% solution in artificial tears.

EDETATE DISODIUM

(ed-a-tayt)

Indications/Pharmacology

Edetate Disodium (Sodium EDTA) is a chelating agent that is also used to stop the melting effect of collagenases and proteases on the cornea. EDTA is useful in halting melting through inhibition of matrix metalloproteinases, but is not felt to be useful for melting caused by infectious agents. As the effect of EDTA on metalloproteinases is reversible, it must be administered several times daily to be effective.

Suggested Dosages/Precautions/Adverse Effects

0.05%–1% Solution applied as 1 drop in the affected eye several times daily.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

EDTA solutions must be compounded by an appropriately trained compounding pharmacist.

Principles of Compounding Ophthalmic Products

GIGI DAVIDSON, DICVP

Physiochemical Considerations for Compounding Ophthalmic Preparations

The availability of suitable commercially available products for every veterinary ophthalmic indication is highly unlikely. Many agents used in veterinary ophthalmology are no longer or never were commercially available. Examples of agents that are commonly used by veterinarians but are no longer commercially available currently include oxytetracycline ophthalmic ointment, idoxuridine ophthalmic solution and ointment, miconazole solution, vidarabine ophthalmic solution, trifluridine ophthalmic solution, tetracycline ophthalmic solution, rose bengal solution, and chloramphenicol ophthalmic ointment. Even if commercially available, products may be of inappropriate concentration to achieve a therapeutic effect in a given patient (e.g., cyclosporine A) or may have agents and excipients that have adverse effects in animal patients (e.g., neomycin sulfate in cats). In other cases, no product is commercially available and must be compounded from other non-ophthalmic drugs or from bulk chemicals (e.g., acetylcysteine ophthalmic solution and disodium edetate ophthalmic solution). For these reasons, pharmacists are frequently called upon to compound products to be used in the animal eye. These products may be administered topically in the form of solutions, suspensions or ointments, by periocular or intraocular injection, by drug-implanted collagen shields, or by drug-impregnated disposable contact lens delivery systems. The quality and sterility of these products is critical. To ensure adequate stability, uniformity, and sterility, both the American Society of Health-Systems Pharmacists and the United States Pharmacopoeial (USP) Convention have published guidelines for pharmacy-prepared ophthalmic products (See Appendix 1). These guidelines address the following areas of concern.

Validation of Formulation

Before compounding any product for ophthalmic use, the pharmacist should obtain documentation that substantiates the stability, safety and benefit of the requested formulation. Pharmacists may call the manufacturer of the drug, refer to primary literature, call regional eye centers, or call professional compounding organizations to obtain such information. If no such documentation is available, the pharmacist must employ professional judgment in determining a suitable formulation for ophthalmic administration. Factors to consider when making this judgment include: sterility, tonicity, pH and buffering, toxicity of the drug, need for preservatives, solubility, stability in the chosen vehicle, viscosity, packaging, and any precautions necessary to keep drug residues from occurring in any food-producing animals.

Documentation

A written procedure for each ophthalmic product compounded should be recorded and kept in a readily retrievable place. This master formulation sheet should indicate the name of the product, the dosage form, the specifications and source of each ingredient used, the weights and measures of each ingredient used, the equipment required, a complete description of each step in the compounding process with special notation of aseptic techniques utilized and which method of terminal sterilization is appropriate, beyond-use

dating, storage requirements, specific packaging requirements, sample label and auxiliary labeling, quality control testing performed, and references for formula. Production records for each batch should include the date of compounding, lot or batch number assigned, the manufacturer and lot number and expiration date of each ingredient used, a sign-off provision for compounder and checker, the amount compounded, and the projected beyond-use date for the batch compounded.

Sterility

Ophthalmic dosage forms must be compounded in aseptic conditions. Sterility is the most important consideration for ophthalmic products. Contaminated ophthalmic products can result in eye infections leading to blindness or even loss of the eye, especially if pathogens such as *Pseudomonas* are present. Eye infections from contamination can also lead to systemic infections requiring hospitalization and may even result in death. All ophthalmics should be compounded in a laminar flow hood that has undergone annual checkups and certification of acceptable performance. It is also important to note that the laminar flow hood does not guarantee sterility. The compounding pharmacist must also use impeccable aseptic technique when handling products intended for use in the eye. (See Appendix 2 for standard operating procedures in a laminar airflow hood.) All products must be rendered sterile after formulation in the laminar flow hood. Sterilization of the final product is most easily achieved through filtration through 0.2 μ filters, which also remove particulate matter. This method is obviously only suitable for ophthalmic solutions. Ophthalmic suspensions and ointments must be sterilized by other means to avoid filtering out active drug. Other methods of sterilization available to the pharmacist include dry heat, autoclaving, and ethylene oxide gas sterilization. Gamma radiation is also commercially available for bulk sterilization, but is very expensive. Preservatives may also be added to prevent bacterial growth, especially if the container is intended for multiple use. The preservative selected must be compatible with the active drug and excipients as well as non-toxic to the eye or to the patient. A description of commonly used ophthalmic preservatives and maximal concentrations is provided in Table 1.

Table 1. Agents used for preserving ophthalmic products.

Agent	Maximum concentration (%)*
Benzalkonium chloride	0.01
Benzethonium chloride	0.01
Phenylmercuric acetate	0.004
Phenylmercuric nitrate	0.004
Methylparaben	0.2
Propylparaben	0.04
Thiomersol	0.01
Chlorobutanol	0.5

*As recommended by FDA Advisory Review Panel on OTC Ophthalmic Drug Products

Clarity

Drugs prepared as ophthalmic solutions should be free from foreign particles. This can be accomplished through filtration with a 0.45 μ filter needle attached to a sterile syringe, or through the use of clarifying agents such as polysorbate 20 (maximum of 1%) and polysorbate 80 (maximum of 1%). Drugs prepared as ophthalmic suspensions, obviously cannot be filtered, but must be of a particle size that does not irritate or scratch the cornea. A micronized form

of the drug is required. The use of an ointment mill is highly recommended to decrease particle size for ophthalmic ointments.

Tonicity

Ophthalmic products do not need to be isotonic if the contact time with the cornea is only for a few minutes. The eye can tolerate a range of 200 – 600mOsm/L for short periods of time. For ointments, irrigations and products that will remain in contact with the eye longer than a few minutes, isotonic products should be used. Hypotonic agents may cause corneal edema and hypertonic agents may dehydrate the cornea and cause pain. Tear fluid and normal saline have identical osmotic pressures making 0.9% sodium chloride an excellent vehicle for ophthalmic products. For products that are hypotonic, sodium chloride equivalencies can be used to determine how much sodium chloride to render the product isotonic. (Fig. 1)

Buffering and pH

Ophthalmic preparations are generally buffered in a range from 4.5 – 11.5. Buffering is necessary to provide maximal stability of the drug or for comfort and safety of the patient. Alkaloids such as atropine and pilocarpine are usually buffered. If the activity and stability of the drug are not pH dependent, and the pH of the product is not irritating, then buffers may be omitted from the formulation. Commonly used buffers for ophthalmic preparations include Palitzsch buffer, boric acid buffer, boric acid/sodium borate buffer, sodium acetate/boric acid buffer, Sorensen's modified phosphate buffer, Atkins and Pantin buffer solution, Feldman buffer, and Gilford ophthalmic buffer. Formulations for these solutions and ratios required to achieve a desired pH are referenced in the International Journal of Pharmaceutical Compounding, Vol. 2, No. 3 May/June 1998.

Viscosity Enhancers

Because tears and blinking reflexes reduce the total amount of drug available for penetration, an increase in residence time in the eye will increase drug absorption. Increasing the viscosity of the drug is the most common way to prolong contact time. Methylcellulose is the most commonly used agent and is generally formulated at a concentration of 0.25%. Hydroxypropylmethylcellulose is used in concentrations of 0.5 – 1%. Polyvinyl alcohol has also been used in concentrations of 0.5 – 1% w/v. Agents used to increase the viscosity of ophthalmic products are shown in Table 2.

Table 2. Agents used to increase viscosity of ophthalmic solutions and suspensions.

Agent	Maximum Concentration (%)
Hydroxyethylcellulose	0.8
Hydroxypropylmethylcellulose	1.0
Methylcellulose	2.0
Polyvinyl alcohol	1.5
Polyvinylpyrrolidone	1.7

Quality Control

Finished products should be thoroughly inspected visually for clarity and uniformity of suspension. The pH of the final product should always be checked and the value recorded on the master formula record for that batch. Most compounded products should have a pH of 5–7 unless otherwise indicated for stability or penetration of ocular tissue. Practitioners compounding large volumes of ophthalmic products should periodically perform testing to ensure

sterility. Various agencies provide this service. The nearest college of pharmacy can be consulted for a list of providers of this service.

Packaging

Ophthalmic preparations should be packaged in sterile dropper bottles (glass or plastic), or individual doses can be placed in sterile syringes with sterile tip caps. Ointments should be packaged in sterile ointment tubes and heat-sealed.

Beyond Use Dating

The USP/NF standards for preparation of ophthalmic medications indicate that, unless otherwise documented, the beyond-use date for water containing formulations is 14 days. For non-aqueous liquids, the recommendation is not more than 25% of the time remaining until the expiration date of the starting product or six months, whichever is earlier. For all other products, the expiration dating should be the duration of therapy or 30 days whichever is shorter. These beyond-use recommendations can be extended in the face of supporting, valid, scientifically conducted stability information.

Considerations for use of ophthalmics in veterinary patients

Veterinary patients experience many of the same ophthalmic diseases and conditions as humans, and treatments are often based on human therapy. Animals, however, have a variety of species-related characteristics that might cause human-designed therapies to fail or be toxic. Behavioral characteristics such as grooming may significantly reduce the contact time of ophthalmic agents with the eye, and increase systemic exposure through ingestion. Anatomical differences such as size must be considered. Horses and other large animals may simply elevate their eyes out of a caregiver's reach if ophthalmic treatments are objectionable. Specialized delivery devices have been created to treat these patients. Subcutaneous palpebral lavage systems are tunneled under the skin over the animal's brow and allow for passage of medication through long catheters that are easily reachable by caregivers. Food-producing animals require special consideration. Systemic absorption of ophthalmic agents in food-producing animals could result in violative drug residues in food intended for human consumption.

General Principles of Ocular Penetration

Corneal penetration

Drugs must generally be administered topically to treat corneal and intraocular conditions. While the eye would appear to be an easy target for topical administration, the eye has several anatomical barriers to prevent penetration by foreign substances. Instantaneous tear production, strong blinking reflexes, and alternating layers of lipophilic and hydrophilic tissue all work in conjunction to prevent entry of foreign substances. The clear tissue known as the cornea covers the visible outer surface of the eye between the lids. The cornea must be clear in order to allow for vision, and nature has accomplished this by omitting blood vessels in the cornea. Because of this lack of vascular tissue, systemically administered drugs do not penetrate into the cornea. The cornea is composed of several layers of lipophilic (outer layers) and hydrophilic (inner layer) tissue. For a topically administered drug to fully penetrate the cornea, the drug must be able to exist in ready equilibrium between both ionized and non-ionized forms (e.g., chloramphenicol, atropine, and pilocarpine). Most antibiotics are water-soluble and will not penetrate the lipophilic outer layer of the cornea unless ulcers are present. Small molecular weight (<350) and high local concentra-

tion of drugs will also increase penetration even if the drugs are ionized and hydrophilic. Topical administration is ideal as it allows for very high local concentrations of drug on the cornea. For a topically administered drug to reach the anterior chamber and bind to intraocular structures (*e.g.*, ciliary body, iris, aqueous humor), the drug must pass through the cornea. Drugs may also reach the anterior chamber to some extent by passive absorption through the conjunctiva.

Key points for corneal penetration of drugs:

- lipophilic
- equilibrium between ionized and non-ionized forms
- small molecular weight (<350)
- high local concentrations

Intravitreal Penetration:

Topically administered drugs reach the vitreous only in very small concentrations. To treat severe conditions of the anterior chamber (uveitis) as well as intravitreal conditions, drugs must be administered by periocular or intraocular injection. The periocular routes include subconjunctival injection and sub-Tenon's membrane injection while the intraocular routes are intracameral injection (directly into the aqueous humor) or intravitreal injection (directly into the vitreous humor). Periocular injections can be administered under sedation and topical anesthesia. Intraocular injections are usually only performed in the operating room while the patient is completely anesthetized. These routes bypass the outermost chemical and physical ocular defenses and allow for better concentration of drug in the vitreous. The volume of administration for these routes is relatively small. Periocular injections should not exceed 0.5 – 1.0 mL in small animals and 2 mL in large animals. Intraocular injections should not exceed 0.1 mL in small animals and 0.25 mL in large animals due to the risk in increasing intraocular pressure. Drugs injected into the eye should be free of preservatives and buffers.

Route of Therapy for Given Ocular Target:

Tissue	Routes of Administration
Eyelids	Topical, systemic
Corneal surface	Topical
Anterior segment	Topical if good penetration or mild disease Systemic if poor penetration or severe disease
Posterior segment	Systemic or intraocular injection (rarely)
Any site where multiple dosing is impractical	Subconjunctival depot injection

Questions to Ponder Prior to Compounding Ophthalmic Products

- Where is the target of therapy? (eyelids, corneal surface, cornea, anterior segment, posterior segment)
- What is the character of the drug?
 - Lipophilic? Hydrophilic?
 - What is the molecular weight?
 - What is the inherent toxicity of the drug to the eye (gentamicin)? To the caregiver (chloramphenicol); to the patient (neomycin sulfate in cats)?
 - Is there data to support what concentration is necessary for corneal penetration?
 - Is the drug soluble in a vehicle that is not toxic to the eye?
 - If not soluble, will the particle size of the suspension or the ointment scratch the corneal or conjunctiva?
 - What is the pH of the final product? Is this in an acceptable range to avoid irritation (4.5–11.5)?
 - What is the tonicity of the final product? Hypertonic? Hypotonic? How long will the product be in contact with the cornea if not isotonic?
 - Will the viscosity need to be enhanced in order to prolong contact with the eye? Which agent is compatible?
 - What is the duration of therapy? Will the product require preservation if long term multiple use? Which preservative is compatible?

Dermatological Agents, Topical

The following section lists many of the active ingredients and corresponding preparations used topically for their local action in veterinary medicine. It includes both veterinary-labeled dermatological products and some potentially useful human-labeled products. Active ingredients are listed by therapeutic class. Products that are applied topically, but are absorbed systemically and used primarily for their systemic effects are found in the general monograph section. For veterinary products, refer to the complete label for additional information.

Non-Corticosteroid Antipruritics, Topical

ALUMINUM ACETATE SOLUTION (BUROW'S SOLUTION OR MODIFIED BUROW'S SOLUTION)

(ah-*loo*-mi-num ass-ih-tate)

For otic use, refer to the Otic appendix

Indications/Actions

An astringent antipruritic agent, Burow's solution can be useful for adjunctive treatment of moist dermatitis conditions. Burow's solution also has acidifying qualities and is mildly antiseptic.

Suggested Dosages/Precautions/Adverse Effects

Topical use of Burow's solution (alone) is usually as a wet compress or dressing. Application for 15–30 minutes is generally recommended and the affected area is air-dried between applications. Use can be as often as necessary, but every 4–6 hours is often employed. The veterinary-labeled products containing hydrocortisone may be directly applied. As Burow's solution products come in various dosage forms (powder or tablets for dissolving, liquid); refer to package directions for proper dilutions. Dilutions of 1:40, 1:20, or 1:10 are commonly used.

Do not use plastic or any occlusive dressing material to prevent evaporation. Use room temperature water for dissolving and application. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

May cause skin irritation on some patients.

Veterinary-Labeled Aluminum Acetate Solution Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Cort/Astrin Solution® (Vedco)	Solution: all products contain: Hydrocortisone 1%; Burow's Solution 2%	OTC (Vet)	1 oz. dropper btl, 16 oz.
Corti-Derm Solution®	Solution	OTC (Vet)	1 oz.
Hydro-Plus® (Phoenix)	Solution	OTC (Vet)	1, 2, 16 oz.
Bur-O-Cort 2:1® (Q.A. Labs)	Solution	OTC (Vet)	1, 16 oz.
Hydro-B 1020® (Butler)	Solution	OTC (Vet)	1, 2, 16 oz.

Human-Labeled Aluminum Acetate Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Bluboro Powder® (Allergan Herbert)	Powder Packets: Aluminum sulfate and Calcium acetate 1.8 g	OTC (Human)	Packets of 12 or 100/box. One packet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Burow's sol.
Domeboro Powder® (Miles)	Powder Packets: Aluminum sulfate and Calcium acetate	OTC (Human)	Packets of 12 or 100/box. One packet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Burow's sol.
Pedi-Boro Soak Paks® (Pedinol)	Powder Packets: Aluminum sulfate and Calcium acetate 2.7 g	OTC (Human)	Packets of 12 or 100/box. One packet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Burow's sol.
Buro-Sol® (Doak)	Powder Packets: Aluminum acetate 0.23%	OTC (Human)	12 packets/box

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Domeboro Tablets® (Miles)	Effervescent Tablets: Aluminum sulfate and Calcium acetate	OTC (Human)	Tablets of 12 or 100/box. One tablet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Burow's sol
Burow's Solution (various)	Solution: Aluminum acetate (Burow's)	OTC (Human)	480 mL bottles

DIPHENHYDRAMINE HCL, TOPICAL

(dye-fen-hye-dra-meen) Benadryl®

For systemic use, see the monograph found in the main section

Indications/Actions

A first generation antihistamine, diphenhydramine has some local anesthetic activity that probably is its main antipruritic mechanism of action. Diphenhydramine may be absorbed in small amounts transdermally, but should not cause systemic side effects.

Precautions/Adverse Effects

Avoid contact with eyes or mucous membranes. Do not apply to blistered or oozing areas of skin. Clients should wash hands after application or wear gloves when applying.

Prolonged use could potentially cause local irritation and/or hypersensitization.

Veterinary-Labeled Diphenhydramine HCl Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Hista-Calm® Spray (Virbac)	Spray: 2%	Rx (Vet)	In an aqueous vehicle. Also contains Omega-3 & 6 essential fatty acids. 59 mL. Shake well before use; labeled for use on dogs or cats 2–3 times a day
Resihist® Leave-On Conditioner (Virbac)	Conditioner: 2%	Rx (Vet)	Water, cetyl alcohol base. 8, 16 oz. Labeled for use on dogs and cats
Histacalm® Shampoo (Virbac)	Shampoo: 2%	Rx (Vet)	Colloidal oatmeal base; also contains Omega-6 fatty Acids. 8, 16 oz; 1 gal. Labeled for use on dogs and cats

Human-Labeled Diphenhydramine HCl Topical Products

Product (Company)	Forms: Concentration	Label Status	Other Ingredients; Size(s); Comments
Products include: Benadryl® , Dermamycin® , Ziradryl® , Caladryl® (various manufacturers and additional trade name modifiers such as Maximum Strength, etc may be found)	Spray: 2% Lotion: 1% Gel: 1%, 2% Cream: 1%, 2%	OTC (Human)	These products may also contain astringents (calamine, zinc acetate), other antihistamines (pyrilamine), and /or counterirritants (menthol, camphor)

PRAMOXINE HCL, TOPICAL

(pra-moks-eeen)

Indications/Actions

A surface and local anesthetic to peripheral nerves not related structurally to procaine-type anesthetics, pramoxine is often added to other topicals to reduce pain and/or itching.

Suggested Dosages/Precautions/Adverse Effects

Depending on the product labeling, pramoxine 1% may be applied every 3–4 hours. Peak local anesthetic effects occur within 3–5 minutes of application. It provides only temporary effects.

Avoid contact with eyes; pramoxine is too irritating for ophthalmic use. Depending on product labeling, clients should wash hands after application or wear gloves when applying.

Adverse effects are unlikely, but localized dermatitis is possible.

Veterinary-Labeled Pramoxine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Micro-Pearls Advantage Dermal-Soothe® Anti-Itch Spray (Evsco)	Spray: 1%	OTC (Vet)	Lactamide monoethanolamine and Novasome® microvesicles. 12 oz. Shake well and repeat as necessary.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Relief® Spray (DVM)	Spray: 1%	OTC (Vet)	Colloidal oatmeal. 8 oz. For dogs or cats. Labeled for daily use or as directed by DVM
Pramoxine Anti-Itch® Spray (Davis)	Spray: 1%	OTC (Vet)	8 oz. For dogs or cats. Labeled for daily use or as directed by DVM
Resiprox® Leave-On Lotion (Virbac)	Lotion: 1.5%	Rx (Vet)	Water, cetyl alcohol, stearyl alcohol base. 8 oz. Shake well. Use daily or as directed by DVM
Micro-Pearls Advantage Dermal-Soothe® Anti-Itch Shampoo (Evsco)	Shampoo: 1%	OTC (Vet)	Colloidal Oatmeal, <i>Novasome®</i> microvesicles, Skin respiratory factor. 12 oz, 1 gal. Labeled for dogs, cats, horses.
Pramoxine Anti-Itch® Shampoo (Davis)	Shampoo: 1%	OTC (Vet)	Colloidal oatmeal, emollients. 12 oz, 1 gal. Labeled for dogs, cats, puppies, kittens
Relief® Shampoo (DVM)	Shampoo: 1%	OTC (Vet)	Colloidal oatmeal, Omega-6 FA's. 8, 12 oz, 1 gal.
Micro-Pearls Advantage Dermal-Soothe® Anti-Itch Cream Rinse (Evsco)	Rinse: 1%	OTC (Vet)	Colloidal Oatmeal, <i>Novasome®</i> microvesicles, Skin respiratory factor. 12 oz, 1 gal. Labeled for dogs, cats, horses.
Pramoxine Anti-Itch® Creme Rinse (Davis)	Rinse: 1%	OTC (Vet)	Colloidal oatmeal, emollients, Omega-6 FA's. 12 oz, 1 gal. Labeled for dogs, cats, puppies, kittens
Relief® Creme Rinse (DVM)	Rinse: 1%	OTC (Vet)	Colloidal oatmeal, emollients, Omega-6 FA's. 8, 12 oz, 1 gal.

Human-Labeled Pramoxine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
AmLactin® AP (UpsherSmith)	Cream: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
Prax® (Ferndale)	Lotion: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
Tronothane® (Abbott)	Lotion: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
Itch-X® (Ascher)	Spray: 1%	OTC (Human)	Benzyl alcohol 10%, aloe vera gel. 60 mL.
Itch-X® (Ascher)	Gel: 1%	OTC (Human)	Benzyl alcohol 10%, aloe vera gel. 35.4 g.
PrameGel® (GenDerm)	Gel: 1%	OTC (Human)	0.5% menthol, emollient base, benzyl alcohol. 118 g.

COLLOIDAL OATMEAL

(ko-loyd-al ote-meel)

Indications/Actions

Colloidal oatmeal is used topically as an antiinflammatory and antipruritic, but an exact mechanism for this effect is not known. It is thought that as the concentration of oatmeal increases, both its drying and antipruritic effects increase; it has been suggested that it may inhibit prostaglandin synthesis.

Precautions/Adverse Effects

Other than the potential for increased drying of already dry skin, colloidal oatmeal is very safe. In humans, there are some reports of contact dermatitis associated with its use.

Veterinary-Labeled Colloidal Oatmeal Products

Note: Products listed are those containing only colloidal oatmeal as the principle active ingredient. For other products that contain colloidal oatmeal, see Diphenhydramine, Pramoxine, Hydrocortisone, Permethrin, or Pyrethrins listings.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Dermapet Dermallay® Conditioner (DermaPet)	Conditioner: 0.75%	OTC (Vet)	8 oz; 1 gal
Epi-Soothe® Cream Rinse and Conditioner (Virbac)	Conditioner: % not listed		8, 16 oz; 1 gal
Resisoothe® Leave-On Conditioner (Virbac)	Conditioner: % not listed		8, 16 oz; 1 gal. Shake well.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Aloe & Oatmeal Skin and Coat Conditioner® (Vet Solutions, RXV, Vedco)	Conditioner: % not listed	OTC (Vet)	Aloe vera gel, vitamins A, D & E, chamomile. 16 oz; 1 gal.
Dermapet Dermallay® Shampoo (DermaPet)	Shampoo: 2%	OTC (Vet)	8 oz; 1 gal
Epi-Soothe® Shampoo (Virbac)	Shampoo: 2%	OTC (Vet)	Chitosanide, glycerin. Ingredients in free form and in <i>Spherulites</i> ®. 8, 16 oz; 1 gal
Cortisoothe Shampoo® (Virbac)	Shampoo: Colloidal Oatmeal % not listed; Hydrocortisone 1%	Rx (Vet)	8, 16 oz. Labeled for dogs and cats.
Pearlyt® Shampoo (DVM)	Shampoo: % not listed	OTC (Vet)	12 oz; 1 gal.
Hartz Living Groomer's Best Oatmeal Shampoo® (Hartz Mountain)	Shampoo: % not listed	Rx (Vet)	18 oz
Aloe & Oatmeal Shampoo® (Vet Solutions, RXV, Vedco)	Shampoo: % not listed	Rx (Vet)	Aloe vera. 16 oz; 1 gal.
Foaming Silk Bath® (AAH)	Shampoo: % not listed	Rx (Vet)	Aloe vera, vitamins A & E. 16 oz.

Human-Labeled Colloidal Oatmeal Products

Note: There are several human products available containing colloidal oatmeal, including creams, lotions and products to be added to the bath. Common trade names include: *Aveeno*®, *Geri SS*®, and *Actibath*®.

PHENOL/MENTHOL/CAMPHOR

(fee-nol; men-thol; kam-for)

Indications/Actions

When used in low concentrations, these agents can be used as counterirritants and may be added to proprietary or compounded products primarily as antipruritics. Camphor and phenol may also have some antiseptic properties.

Precautions/Adverse Effects

These compounds may cause local irritation and should not be used around or in eyes. Products containing phenol should not be used on cats.

Veterinary-Labeled Phenol, Menthol, or Camphor Products

Note: There are also several over the counter products not listed containing menthol, phenol or camphor used primarily on equine patients for overexertion, soreness, or stiffness. These include a variety of liniments (e.g., white liniment, Choate's liniment) or gels (e.g., *Cool Gel*®, *Ice-O-Gel*®, *Shin-O-Gel*®, etc.).

Product (Company)	Form: Active Ingredients/Concentrations	Label Status	Other Ingredients; Size(s)
Scarlet Oil Pump Spray (Dominion)	Spray: Menthol, Phenol, Oil of Camphor, Oil of Eucalyptus & Oil of Pine each at 7.5mg/mL; Oil of Thyme 2.8mg/mL; Peru Balsam 1.5mg/mL; Biebrich Scarlet Red 100 ppm.	OTC (Vet)	500 mL. Labeled for superficial cuts, wounds, burns, etc for horses and mules. Shake well.

LIDOCAINE, TOPICAL LIDOCAINE/PRILOCAINE (EMLA CREAM)

(lye-doe-kane; pry-loe-kane)

For systemic use of lidocaine, see the monograph found in the main section

Indications/Actions

Lidocaine is used topically as a dermal anesthetic or antipruritic and is included in several "hot spot" (acute moist dermatitis, pruritic lesions) products. When combined with prilocaine (commonly called EMLA cream), it may be useful for dermal anesthesia prior to invasive procedures (e.g., catheter placement, etc).

Lidocaine exerts its anesthetic properties via alteration of cell membrane ion permeability, thereby inhibiting conduction from sensory nerves.

Precautions/Adverse Effects

Topical lidocaine may be absorbed systemically, but systemic toxicity is unlikely to occur unless used on a significant percentage of body area, for prolonged times or at high concentrations. Be extra vigilant in patients also receiving Class I antiarrhythmics (lidocaine, mexiletine, or tocainide). Avoid contact with eyes and do not use in ears, unless specifically labeled for such. Clients should wash hands after application or wear gloves when applying.

Hypersensitivity or skin irritation (burning, tenderness, etc) are possible, but apparently occur uncommonly. Products containing prilocaine (EMLA), may be more prone to causing (rarely) methemoglobinemia or systemic toxicity.

Veterinary-Labeled Lidocaine Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Allercaine ® (Tomlyn)	Spray: 2.4%	OTC (Vet)	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%. 4, 12 oz. Do not apply to entire body or to large areas of broken skin.
Allerspray ® (Evsco)	Spray: 2.4%	OTC (Vet)	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%, aloe vera gel, allantoin, PEG-75 lanolin. 4 oz.
Dermacool w/ Lidocaine Spray ® (Virbac)	Spray: Concentration not listed	OTC (Vet)	Hamamelis extract, menthol. 4 oz
Hexa-Caine ® (PRN Pharmacal)	Spray: 2.4%	OTC (Vet)	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%, aloe vera gel, allantoin, lanolin. 4, 8, 16 oz.
Biocain ® (Tomlyn)	Lotion: 2%	OTC (Vet)	Bittran® II (bittering agent), Benzalkonium Chloride 0.1%. 2, 4 oz.

Human-Labeled Lidocaine Topical Products

There are also several topical OTC products listed for human use, including sprays (2–2.5%), liquids (2–4%), creams (0.5–2%), gels (0.5–2.5%) and topical patches.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
EMLA ® (Astra) Lidocaine/Prilocaine Cream (Generic various)	Cream: Lidocaine 2.5%; Prilocaine 2.5%	Rx (Human)	Depending on manufacturer: 5, 15, 30 g.

Antiinflammatory Agents, Topical

Corticosteroids, Topical

Note: There are at least 20 chemical entities (plus a variety of salts) used in humans for topical corticosteroid therapy. The following section includes many veterinary topical products and some human products that may be of use in veterinary medicine. Also, see the *Otic* section for more products.

HYDROCORTISONE

(TOPICAL)

(hye-droe-kor-ti-zone)

Indications/Actions

Considered a low potency topical corticosteroid, hydrocortisone may be useful for adjunctive treatment of pruritic conditions. Because risks associated with hydrocortisone are significantly less when compared to higher potency corticosteroids, hydrocortisone is a reasonable first choice, particularly when treating large areas, or when used on smaller patients. Some products also contain the astringent Burow's solution, which may have additional antipruritic effects.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Dosages/Precautions/Adverse Effects

Initially, topical corticosteroids are usually used sparingly 2–4 times per day. Refer to individual product labeling for actual dosing recommendations for veterinary products.

Several veterinary topical products list tuberculosis of the skin or pregnancy as contraindications. Clients should wash hands after application or wear gloves when applying.

Local skin reactions are possible, but unlikely to occur. Atrophy associated with skin fragility and comedones may be seen with long term, frequent use. Although systemic absorption is rare with hydrocortisone, long term use may lead to HPA axis suppression.

Veterinary-Labeled Hydrocortisone Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Corticalm Lotion® (DVM)	Lotion: 1%	Rx (Vet)	3, 6 oz.
Sulfodene HC Anti-Itch Lotion® (Farnam)	Lotion: 0.5%	OTC (Vet)	1.5 oz.
Cortispray® (DVM)	Spray: 1%	Rx (Vet)	60 mL. Labeled for use on dogs, cats, horses.
Dermacool HC Spray® (Virbac)	Spray: 1%	Rx (Vet)	Hamamelis extract, lactic acid, menthol, propylene glycol. 2, 4 oz.
Hartz Advanced Care Hydrocortisone Spray w/Aloe® (Hartz Mountain)	Spray: 0.5%	OTC (Vet)	Aloe. 5 oz.
Hartz Advanced Care Extra Strength Hydrocortisone Spray w/Bitrex® (Hartz Mountain)	Spray: 0.75%	OTC (Vet)	Bitrex (bittering agent), aloe. 5 oz.
Cort/Astrin Solution® (Vedco)	Solution: all products contain: Hydrocortisone 1% Burow's Solution 2%	OTC (Vet)	1 oz dropper btl, 16 oz.
Corti-Derm Solution® (First Priority)		OTC (Vet)	1 oz.
Hydro-Plus® (Phoenix)		OTC (Vet)	1, 2, 16 oz.
Bur-O-Cort 2:1® (Q.A. Labs)		OTC (Vet)	1, 16 oz.
Hydro-B 1020® (Butler)		OTC (Vet)	1, 2, 16 oz.
Cortisoothe Shampoo® (Virbac)	Shampoo: 1%	Rx (Vet)	Colloidal oatmeal base. 8, 16 oz. Labeled for use on dogs and cats.
Hartz Advanced Care Hydrocortisone Shampoo w/Aloe® (Hartz Mountain)	Shampoo: 0.5%	OTC (Vet)	Aloe. 8 oz.
Resicort Leave-On Conditioner® (Virbac)	Conditioner: 1%	Rx (Vet)	8, 16 oz.
Hartz Advanced Care Hydrocortisone Spot®	Liquid Spot: 0.5%	OTC (Vet)	3 x 3 mL tubes. For dogs and cats

Human-Labeled Hydrocortisone Topical Products

Note: Partial listing. There are many branded products available with hydrocortisone; these will be listed only when they have relatively unique formulations and concentrations. For more information on human-labeled hydrocortisone products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s)
Hydrocortisone Ointment	Ointment: 0.5, 1%	OTC/Rx (Human). Status determined by labeling	15, 20, 28.4, 30, 60, 120, 454 g.
Hydrocortisone Ointment	Ointment: 2.5%	Rx (Human)	20, 30 g
Hydrocortisone Cream	Cream: 0.5, 1%	OTC/Rx (Human). Status determined by labeling	1 g pkts, 15, 20, 28.4, 30, 60, 120, 454 g.
Hydrocortisone Cream	Cream: 2.5%	Rx (Human)	15, 20, 30, 60, 240, 454 g
Hydrocortisone Lotion	Lotion: 0.5, 1%	OTC/Rx (Human). Status determined by labeling	30, 60, 120 mL.
Hydrocortisone Lotion	Lotion: 2.5%	Rx (Human)	60, 120mL
Extra-Strength CortaGel® (Norstar)	Gel: 1%	OTC (Human)	15, 30 g
Alcortin® (Primus)	Gel: 2%	Rx (Human)	2 g
Texacort® (GenDerm)	Solution: 1%, 2.5%	Rx (Human)	30 mL
Penecort® (Allergan)	Solution: 1%	Rx (Human)	30, 60 mL
Scalpicin® (Combe)	Liquid: 1%	OTC (Human)	Menthol. 45, 75, 120 mL
T/Scalp® (Neutrogena)	Liquid: 1%	OTC (Human)	60, 600 mL.
Procert® (Roberts)	Spray: 1%	OTC (Human)	45 mL.

Product (Company)	Form: Concentration	Label Status	Size(s)
Cortizone-10 Quickshot® (Pfizer)	Spray: 1%	OTC (Human)	44 mL.
Maximum Strength Cortaid® (Pharmacia Upjohn)	Pump Spray: 1%	OTC (Human)	45 mL.

TRIAMCINOLONE ACETONIDE

(TOPICAL)

(trye-am-sin-ohe-lone ass-si-toe-nide)

For systemic use, see the monograph found in the main section.

Indications/Actions

Considered a medium potency topical corticosteroid when used at concentrations less than 0.5% (high potency), triamcinolone acetate may be useful for adjunctive treatment of pruritic conditions. Because risks associated with triamcinolone (HPA axis suppression, skin atrophy) are greater than with hydrocortisone, triamcinolone acetate products are generally reserved for more serious pruritic conditions or when hydrocortisone is not effective. Triamcinolone can be found in a veterinary-labeled sole agent cream (*Medalone®*) or spray (*Genesis®*). It is also an ingredient in combination with antibiotics and anti-yeast ingredients in several veterinary products (e.g., *Panalog®*).

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Dosages/Precautions/Adverse Effects

Initially, topical corticosteroids are usually used sparingly 2–4 times per day. Refer to individual product labeling for actual dosing recommendations for veterinary products.

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy (skin fragility, due to atrophy, alopecia, localized pyoderma and comedones are other possible complications) occur as product concentration and duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

Veterinary-Labeled Triamcinolone Acetonide Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Medalone Cream® (Med-Pharmex)	Cream: 0.1%	Rx (Vet)	7.5, 15 g. Approved for dogs. Indications include allergic dermatitis and summer eczema.
Genesis Topical Spray® (Virbac)	Spray: 0.015%	Rx (Vet)	16 oz spray bottle. Approved for dogs. Indication is for control of pruritus associated with allergic dermatitis. Bacterial skin infection needs to be resolved prior to use. Strongly recommend referring to the package insert information for maximum allowable dosages, treatment durations, etc.
Panalog Cream® (Fort Dodge) Cortalone Cream® (Vedco) Derma-Vet Cream® (Med-Pharmex)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx (Vet)	Aqueous vanishing cream. 7.5, 15 g. Panalog and Derma-Vet labeled for use in dogs or cats. Cortalone labeled for dogs only.
Panalog Ointment® (Fort Dodge) Animax Ointment® (Pharmaderm) Quadratop Ointment® (Butler) Derma-Vet Ointment® (Med-Pharmex) Dermalog Ointment® (RXV) Dermalone Ointment® (Vedco)	Ointment: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx (Vet)	7.5, 15, 30, 240 mL. Labeled for use in dogs or cats.

Human-Labeled Triamcinolone Acetonide Topical Products:

Note: Partial listing. There are several topical branded products (two common trade names are *Aristocort*® and *Kenalog*®) available with triamcinolone. For more information on human-labeled triamcinolone products, refer to a comprehensive human drug reference (*e.g.*, *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s); Comments
Triamcinolone Acetonide Ointment	Ointment: 0.025, 0.1, 0.5%	Rx (Human)	15, 20, 28.4, 30, 60, 120, 454 g.
Triamcinolone Acetonide Cream	Cream: 0.025, 0.1, 0.5%	Rx (Human)	15, 20, 30, 60, 120, 240 454 g.
Triamcinolone Acetonide Lotion	Lotion: 0.025, 0.1%	Rx (Human)	15, 60 mL.
Kenalog ® (Westwood Squibb)	Aerosol Spray: 0.1%	Rx (Human)	23, 63 g. 10.3% alcohol
Nystatin-Triamcinolone Acetonide (various) Mycogen II ® (Goldline) Mycolog-II ® (Bristol Meyers Squibb) Myco-Triacet II ® (Lemmon) Myconel ® (Marnel)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 0.1%	Rx (Human)	Depending on product: 1.5 g. pkts, 15, 30, 60, 120 g.
Myco-Biotic II ® (Moore)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 0.1% Neomycin Sulf. 0.5%	Rx (Human)	Aqueous vanishing cream w/ white petrolatum. 15, 30, 60, 454 g.

BETAMETHASONE**(TOPICAL)****(bet-ah-meth-ah-zone)**

For systemic use, see the monograph found in the main section

Indications/Actions

Considered a high potency topical corticosteroid, betamethasone may useful for adjunctive treatment of localized pruritic or inflammatory conditions. Because risks associated with betamethasone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, betamethasone products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products are in combination with gentamicin and labeled indications are for treatment of infected superficial lesions caused by bacteria sensitive to gentamicin. Sole ingredient betamethasone topical forms are available with human labeling.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (*e.g.*, histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Dosages/Precautions/Adverse Effects

Initially, topical corticosteroids are usually used sparingly 2–4 times per day. Refer to individual product labeling for actual dosing recommendations for veterinary products.

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy occur as product concentration and duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur. Betamethasone may delay wound healing particularly if used longer than 7 days in duration.

Veterinary-Labeled Betamethasone Topical Products

Note: At time of writing there are no veterinary-labeled sole active ingredient betamethasone products in the USA.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Gentocin Topical Spray® (Schering)	Spray (all products listed): Gentamicin 0.57 mg/mL; Betamethasone (as valerate) 0.284 mg/mL	Rx (Vet)	72 mL.
Gentaspray® (Butler)		Rx (Vet)	60 mL.
Betagen Topical Spray® (Med-Pharmex)		Rx (Vet)	60, 120, 240 mL.
Gentamicin Topical Spray® (RXV)		Rx (Vet)	60, 120 mL.
Gentaved Topical Spray® (Vedco)		Rx (Vet) Rx (Vet)	60, 120, 240 mL. 15 g, 30 g. Extra label use on localized lesions on the skin, e.g., bacterial
Otomax® Ointment (Schering)	Ointment (otic): Gentamicin 3 mg/g; Betamethasone (as valerate) 1 mg/g; Clotrimazole 10 mg/g	Rx (Vet)	Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; 7.5 & 15 g tubes
DVMAX® Ointment (IVX)	Ointment (otic): Gentamicin 3 mg/g; Betamethasone (as valerate) 1 mg/g; Clotrimazole 10 mg/g	Rx (Vet)	Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; 10, 20 & 215 g bottles

Human-Labeled Betamethasone Topical Products

Note: Partial listing. There are also topical branded products (two common trade names are *Diprosone®* and *Maxivate®*) available with betamethasone dipropionate. Do not confuse products containing augmented betamethasone dipropionate (*Diprolene®*, etc) with betamethasone dipropionate. Augmented betamethasone dipropionate is not equivalent with betamethasone dipropionate as it is more potent. For more information on human-labeled betamethasone products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s); Comments
Betamethasone Dipropionate Ointment	Ointment: 0.05%	Rx (Human)	15, 45 g.
Betamethasone Dipropionate Cream	Cream: 0.05%	Rx (Human)	15, 45 g.
Betamethasone Dipropionate Lotion	Lotion: 0.05%	Rx (Human)	20, 30, 60 mL.
Diprosone® (Westwood Squibb)	Aerosol Spray: 0.1%	Rx (Human)	85 g. 10% isopropyl alcohol, mineral oil
Clotrimazole & Betamethasone Diprop. (Fougera)	Lotion: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	30 mL.
Lotrisone® (Schering)			
Clotrimazole & Betamethasone Diprop. (Fougera)	Cream: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	15, 45 g.
Lotrisone® (Schering)			

ISOFLUPREDONE ACETATE**(TOPICAL)**

(eye-soe-flue-pre-done ass-i-tate)

Indications/Actions

Considered a high potency topical corticosteroid, isoflupredone in combination with neomycin and tetracaine may be useful for adjunctive treatment of otic or topical localized pruritic or inflammatory conditions. Because risks associated with isoflupredone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, these products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products (*Tritop® Ointment* and *Neo-Predef w/Tetracaine Powder®*) have labeled indications for conditions associated with neomycin-susceptible organisms and/or allergy, or as a superficial dressing applied to minor cuts, wounds, lacerations, abrasions and for post-surgical pain application where reduction in pain and inflammatory response is deemed desirable.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Dosages/Precautions/Adverse Effects

Labeled dose for *Tritop*® when used on skin or mucous membranes is: cleanse area, apply a small amount and spread and rub in gently. Involved area may be treated 1–3 times daily and continued in accordance with clinical response.

Labeled dose for *Neo-Predef w/Tetracaine Powder*® is: cleanse area, apply by compressing bottle with short, sharp squeezes; once daily application usually sufficient, but may use 1–3 times as required.

Several veterinary topical products containing corticosteroids list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur. Hypersensitivity reactions to neomycin and/or Tetracaine are possible.

Veterinary-Labeled Isoflupredone Topical Products

Note: At time of writing there are no veterinary-labeled sole active ingredient betamethasone products in the USA.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Tritop ® (Pharmacia & Upjohn)	Ointment: Isoflupredone acetate 0.1%; Neomycin sulfate 0.5%; Tetracaine HCl 0.5%	Rx (Vet)	10 g. tube. Labeled for dogs, cats, horses.
Neo-Predef w/ Tetracaine Powder ® (Pharmacia & Upjohn)	Powder: Isoflupredone acetate 1mg/g; Neomycin Sulf. 5 mg/g; Tetracaine HCl 5 mg/g	Rx (Vet)	Myristyl-gamma-picolinium Cl (germicidal surfactant) 0.2 mg/g. 15 g. insufflator btl. Store in dry place, do not allow tip of bottle to contact moisture.

Human-Labeled Isoflupredone Topical Products: None

Antiinfectives, Topical

Antibacterial Agents

See also the *Sulfur* listing the keratolytic section

GENTAMICIN SULFATE

(TOPICAL)

(jen-ta-mye-sin sul-fate) Gentocin®

For systemic use, see the monograph found in the main section.

Indications/Actions

A bactericidal antibiotic, gentamicin can be useful for treating both primary and secondary superficial bacterial skin infections. It can also be used prophylactically after lacerations/abrasions or after minor surgery. In small animal medicine, topical gentamicin is usually used in combination with the corticosteroid betamethasone to treat superficial lesions, including “hot spots” (acute moist dermatitis, pruritic lesions).

Gentamicin has activity against susceptible bacteria, including many Streptococci, Staphylococci (coagulase negative/positive and some penicillinase-producing strains) and gram-negative bacteria including many Klebsiella, *E. coli*, Pseudomonas (often resistant), etc)

Suggested Dosages/Precautions/Adverse Effects

Topical gentamicin/betamethasone sprays are labeled for use 2–4 times day for up to 7 days. Topical gentamicin creams and ointments are generally applied to affected areas up to four times daily. Creams are generally used for secondary or greasy infections and ointments on dry skin infections.

Topical gentamicin may be absorbed systemically if used on ulcers, burned or denuded skin. Creams are more likely to be absorbed than are ointments. Systemic toxicity is unlikely to occur unless used on a significant percentage of body area or for prolonged times.

Prolonged use, or use over large areas with products containing corticosteroids (betamethasone) may cause adrenal suppression; atrophic skin and comedone formation. Iatrogenic Cushing's syndrome is possible. Vomiting and diarrhea have been reported in small animals with use of the products containing betamethasone.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Veterinary-Labeled Gentamicin Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Gentocin Topical Spray ® (Schering)	Spray (all products listed): Gentamicin 0.57 mg/mL; Betamethasone (as valerate) 0.284 mg/mL	Rx (Vet)	72 mL.
Gentaspray ® (Butler)		Rx (Vet)	60 mL.
Betagen Topical Spray ® (Med-Pharmex))		Rx (Vet)	60, 120, 240 mL.
Gentamicin Topical Spray ® (RXV)		Rx (Vet)	60, 120 mL.
Gentaved Topical Spray ® (Vedco)		Rx (Vet)	60, 120, 240 mL.
Otomax ® Ointment (Schering)	Ointment (otic): Gentamicin 3 mg/g; Betamethasone (as valerate) 1 mg/g; Clotrimazole 10 mg/g	Rx (Vet)	Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; 7.5 & 15 g tubes
DVMAX ® Ointment (IVX)	Ointment (otic): Gentamicin 3 mg/g; Betamethasone (as valerate) 1 mg/g; Clotrimazole 10 mg/g	Rx (Vet)	Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; 10, 20 & 215 g bottles

Human-Labeled Gentamicin Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Gentamicin (various generic)	Cream: 0.1% (as base) Ointment: 0.1% (as base)	Rx (Human) Rx (Human)	Cream may contain propylene glycol and parabens. 15 g tubes Ointment may contain white petrolatum and parabens. 15 g. tubes

BACITRACIN AND BACITRACIN COMBINATIONS**(TOPICAL)**

(bass-ih-trase-in)

Indications/Actions

Bacitracin is used topically to prevent infection after dermal lacerations, scrapes or minor burns. Bacitracin acts by inhibiting cell wall synthesis of susceptible bacteria and is either bactericidal or bacteriostatic depending on drug concentration and bacterial susceptibility. Primarily active against gram-positive bacteria; Staphylococci becoming increasingly resistant. Bacitracin activity is not impaired by blood, pus, necrotic tissue or large inocula. Bacitracin is not recommended in the treatment of ulcerated and chronic canine dermatoses (sensitization may occur).

Suggested Dosages/Precautions/Adverse Effects

May be applied up to 3 times daily and be covered by a suitable dressing. Use is usually not recommended to continue more than one week.

Bacitracin topical ointment should not be used in or around eyes, or in patients known to be hypersensitive to it. There have been anecdotal reports of cats developing fatal anaphylactic reactions after administered ophthalmic “triple” antibiotic ointment. Deep puncture wounds, animal bites or deep cutaneous infections may require systemic antibiotic therapy. While topical administration generally results in negligible systemic levels, if used over large areas of the body or on serious burns or puncture wounds, measurable absorption and potential toxicity may occur. Clients should wash hands after application or wear gloves when applying.

Veterinary-Labeled Bacitracin Topical Products

Product (Company)	Form: Active Ingredients; Concentration	Label Status	Other Ingredients; Size(s); Comments
Vetro-Biotic Ointment ® (Pharmaderm)	Ointment: Bacitracin 400 Units/g; Neomycin 3.5 mg/g; Polymyxin B 5,000 Units/g	Rx (Vet)	White petrolatum. 30 g. Labeled for dogs and cats.

Bacitracin Topical Human-Labeled Products

Bacitracin ointment is available either alone as 500 Units/g in various tube sizes. There are many OTC human products available with formulas equivalent to the veterinary-labeled *Vetro-Biotic*® (Neomycin, polymyxin B, bacitracin). A well-known trade name is *Neosporin*® or it is available generically as Triple Antibiotic Ointment. When combined with only polymyxin B, a common trade name is *Polysporin*®.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Bacitracin (various generic)	Ointment: 500 Units/gram	OTC (Human)	Depending of manufacturer: white petrolatum, mineral oil. 14, 28, 120 g. tubes, 1 lb. jars

BENZOYL PEROXIDE

(ben-zoyl per-oks-ide)

Indications/Actions

Benzoyl peroxide products are used topically either as gels or in shampoos. Shampoos are generally used for seborrheas, greasy skin (seborrhea oleosa), or crusty pyodermas (such as seborrheic dermatitis/pyoderma commonly seen in Cocker Spaniels). Gels may be useful for treating recurrent localized skin infections (e.g., chin acne), localized Demodex lesions, superficial and deep pyodermas (adjunctive therapy), seborrhea oleosa, and Schnauzer comedo syndrome.

Benzoyl peroxide possesses antimicrobial (especially antibacterial), keratolytic and antiseborrheic actions. It also has some mild antipruritic activity and wound healing effects, and is thought to increase follicular flushing. Benzoyl peroxide's antimicrobial activity is due to the oxidative benzoyl peroxy radicals formed that disrupt cell membranes.

Suggested Dosages/Precautions/Adverse Effects

Gels are usually recommended for use once to twice daily and shampoos up to once daily.

Avoid contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Benzoyl peroxide will bleach colored fabrics, jewelry, clothing or carpets and may bleach the patient's fur. Clients should be advised to keep treated animals away from fabrics during treatment.

Benzoyl peroxide can be drying or irritating (erythema, pruritus, pain) in some patients particularly at higher (>5%) concentrations. Use of emollients after treating or using shampoos with moisturizing microvesicles may alleviate or prevent this problem. Benzoyl peroxide shampoos do not lather well.

Veterinary-Labeled Benzoyl Peroxide Topical Products

Product (Company)	Form: Active Ingredients; Concentration	Label Status	Other Ingredients; Size(s); Comments
Pyoben Gel® (Virbac)	Gel: 5%	Rx (Vet)	30 g. Labeled for dogs and cats and for use once or twice daily after cleaning.
Oxydex Gel® (DVM)	Gel: 5%	Rx (Vet)	30 g. Labeled for dogs and cats and for use once or twice daily after cleaning. Rub in well so that no residue remains. Prevent pet from licking area until dries (1–2 minutes).
Micro-Pearls Advantage Benzoyl-Plus® (EvSCO)	Shampoo: 2.5%	Rx (Vet)	<i>Novasome®</i> microvesicles. 12 oz, 1 gal. Labeled for dogs, & cats. Shake well; wear gloves. May be used up to once daily as directed.
Pyoben Shampoo® (Virbac)	Shampoo: 3%	Rx (Vet)	<i>Spherulites®</i> , glycerin, chitosanide. 8 oz. Labeled for dogs or cats. Use initially 2–3 times/week, then once a week or as directed by DVM.
Benzoyl Peroxide Shampoo® (Davis)	Shampoo: 2.5%	OTC (Vet)	12 oz, 1 gal. Labeled for OTC use.
OxyDex Shampoo® (DVM)	Shampoo: 2.5%	OTC (Vet)	8, 12 oz, 1 gal. Labeled for OTC use.
Sulf OxyDex Shampoo® (DVM)	Shampoo: 2.5% Benzoyl Peroxide; 2% Sulfur (micronized).	Rx (Vet)	8, 12 oz, 1 gal. Shake well. May be used prn or as directed by DVM.
Dermapet Dermabens® Shampoo® (DermaPet)	Shampoo: 2.5%	OTC (Vet)	Moisturizing factors, Vitamin E. 8 oz, 1 gal. Labeled for OTC use.

Human-Labeled Benzoyl Peroxide Topical Products

There are many human products available containing benzoyl peroxide, but with the possible exception of the 5% gel products, the veterinary formulations would be more suitable for use on dogs or cats. Benzoyl peroxide 5% gel can be labeled as either Rx or OTC depending on product and are available as generics or with the following trade names: *Benzac®*, *Desquam-X®*, or *PanOxyl®*.

CLINDAMYCIN

(TOPICAL)

(klin-da-mye-sin) Cleocin®

For systemic use, see the monograph found in the main section

Indications/Actions

Topical clindamycin is an optional topical treatment for feline acne.

Clindamycin inhibits bacterial protein synthesis by binding to the 50S ribosome; primary activity is against anaerobic and gram-positive aerobic bacteria. For more information on the pharmacology of clindamycin, refer to the monograph for systemic use found in the main section.

Suggested Dosages/Precautions/Adverse Effects

When used for feline acne, topical clindamycin is generally applied in a thin film once daily.

Topical clindamycin should not be used in patients with a history of hypersensitivity to clindamycin or lincomycin. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Contact reactions (pain, burning erythema, itching, drying, peeling) are possible. Clindamycin lotions and gels may cause less burning than the topical solutions or foams. As clindamycin can be absorbed through the skin, systemic adverse effects are possible. Antibiotic associated diarrheas are potentially possible, but severe, life-threatening diarrheas (so-called Pseudomembranous colitis) are thought to occur very rarely in animal patients when clindamycin is used systemically.

Veterinary-Labeled Clindamycin Topical Products: None

Human-Labeled Clindamycin Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Clindamycin Phosphate (various generic)	Lotion: 1%	Rx (Human)	30, 60 g.
Cleocin T® (Pharmacia Upjohn)	Lotion: 1%	Rx (Human)	Cystostearyl alcohol, glycerin, methylparaben. 60 mL.
Clindamax® (PharmaDerm)	Lotion: 1%	Rx (Human)	Cystostearyl alcohol, glycerin, methylparaben. 60 mL.
Clindamycin Phosphate (various generic)	Gel: 1%	Rx (Human)	30, 60 g.
Cleocin T® (Pharmacia Upjohn)	Gel: 1%	Rx (Human)	Methylparaben. 30, 60 g.
Clindagel® (Galderma)	Gel: 1%	Rx (Human)	Methylparaben. 7.5, 42 & 77 g.
Clindamax® (PharmaDerm)	Gel: 1%	Rx (Human)	Methylparaben. 30, 60 g.
Clindamycin Phosphate (various generic)	Solution: 1%	Rx (Human)	30, 60 mL.
Cleocin T® (Pharmacia Upjohn)	Solution: 1%	Rx (Human)	Isopropyl alcohol 50%. 30 & 60 mL; single-use pledgets
Clindets® (Stiefel)	Solution: 1%	Rx (Human)	Isopropyl alcohol 52%. 1 mL pledgets
Evoclin® (Connetics)	Aerosol Foam: 1%	Rx (Human)	Cetyl alcohol, ethanol 58%, stearyl alcohol. 50 g.

MUPIROCIN (PSEUDOMONIC ACID A)

(myoo-pye-roe-sin) Bactroban®, Bactoderm®

Indications/Actions

Mupirocin is approved for treating topical infections in dogs caused by susceptible strains of *Staphylococcal aureus* or *Staphylococcal intermedius*. It may also be of use in other species and conditions (e.g., feline acne, equine pyoderma, superficial pyoderma, interdigital abscesses, pressure point pyodermas, etc). It also shows activity against other gram-positive pathogens: *Corynebacterium* sp, *Clostridium* sp and *Actinomyces* spp.

Mupirocin is not related structurally to other commercially available antibiotics and acts by inhibiting bacterial protein synthesis by binding to bacterial isoleucyl transfer-RNA synthetase. Its principle activity is against Gram-positive cocci (*Staphylococcal* spp. and *Streptococcal* spp.), including beta-lactamase producing and methicillin-resistant strains. While bacterial resistance is rare, resistant strains of *Staphylococcal aureus* have been identified and resistance transference is thought to be plasmid-mediated. Cross-resistance with other antimicrobials has not been identified. Mupirocin also has activity against some Gram-negative bacteria, but is not used clinically for infections caused by those bacteria.

Mupirocin is not significantly absorbed through the skin into the systemic circulation, but does penetrate well into granulomatous deep pyoderma lesions and is not suitable for application to burns.

Suggested Dosages/Precautions/Adverse Effects

Mupirocin is labeled for twice daily application on dogs. After a course of once to twice daily mupirocin, some cats with feline acne have been maintained (after control is attained) with 1–2 applications per week. In dogs, it requires 10 minutes of contact time to be active.

Mupirocin is contraindicated in patients with a history of hypersensitive reactions to it. Because the ointment has a polyethylene glycol base, the manufacturer warns that nephrotoxicity may potentially develop if used on extensive deep lesions, yet no reports of this occurring were located.

Mupirocin appears to be very well tolerated; contact reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use. Anecdotally, very rare renal toxicity has been reported.

Veterinary-Labeled Mupirocin Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Muricin ® (Pharmaderm)	Ointment: 2%	Rx (Vet)	Labeled for use on dogs; Polyethylene glycol base. 15 g.

Topical Human-Labeled Mupirocin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Mupirocin (various generic)	Ointment: 2%	Rx (Human)	Polyethylene glycol base. Unit dose, 15, 22, 30 g.
Bactroban ® Ointment (GlaxoSmithKline)	Ointment: 2%	Rx (Human)	Polyethylene glycol base. 22 g.
Centany ® (OrthoNeutrogena)	Ointment: 2%	Rx (Human)	Castor oil, hard fat base. 15 & 30 g.
Bactroban ® Cream (GlaxoSmithKline)	Cream: 2%	Rx (Human)	Oil/water base. 15 & 30 g

NITROFURAZONE, TOPICAL

(nye-troe-fur-ah-zone) Furazone®

Indications/Actions

Nitrofurazone can be used topically as an antibacterial for treating or preventing superficial infections. It is a nitrofurant antibacterial that is bactericidal for many bacteria, including *E. Coli*, *Staph aureus*, etc. Nitrofurazone's mechanism of action is thought to be associated with inhibiting bacterial enzymes that primarily degrade glucose and pyruvate.

Precautions/Adverse Effects

Clinical efficacy demonstrating efficacy for the treatment of minor burns or surface bacterial infections is apparently unavailable.

As nitrofurazone has been shown to cause mammary tumors when fed in high doses to rats and ovarian tumors in mice, **U.S.A. federal law prohibits the use of nitrofurazone products in (or on) food animals, including horses to be used for food.**

The soluble dressing contains polyethylene glycols and if used on large areas of denuded skin significant amounts of polyethylene glycol could be absorbed and cause nephrotoxicity.

Avoid contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Avoid exposure to sunlight, strong fluorescent lighting, excessive heat, or alkaline materials.

Topical nitrofurazone appears to be well tolerated; hypersensitivity or skin reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use.

Veterinary-Labeled Nitrofurazone Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Nitrofurazone Soluble Dressing (Generic; Med-Pharmex, AgriLabs, Vedco, etc.) Also available under a variety of trade names.	Ointment (soluble): 0.2%	OTC (Vet)	Water-soluble base. 1 lb. jars.
NFZ ® Puffer (AgriLabs, Durvet, Aspen, etc)	Soluble Powder: 0.2%	OTC (Vet)	45 g. Labeled for eye and ear infections, surface wounds, cuts and abrasions in dogs and cats. Shake or rotate to loosen powder. Restricted drug in California.

Human-Labeled Nitrofurazone Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Nitrofurazone (various)	Topical Solution: 0.2%	Rx (Human)	1 pt. & 1 gal.
Furacin ® (Roberts)	Topical Solution: 0.2%	Rx (Human)	1 pt.
Nitrofurazone (various)	Ointment (soluble): 0.2%	Rx (Human)	1 lb.
Furacin ® (Roberts)	Ointment (soluble): 0.2%	Rx (Human)	Polyethylene glycol base. 28, 56 & 454 g.
Furacin ® (Roberts)	Cream: 0.2%	Rx (Human)	Water-miscible base: Cetyl alcohol, mineral oil. 28 g.

SILVER SULFADIAZINE (SSD)**(TOPICAL)****(sil-ver sul-fa-dye-ah-zeen)** Silvadene®**Indications/Actions**

Topical silver sulfadiazine (SSD) is used topically for prophylaxis and treatment of 2nd and 3rd degree burns. It is also useful in treating localized pyodermas caused by *Pseudomonas* spp.

SSD has extensive antimicrobial activity and is bactericidal for yeasts and many gram-negative and gram-positive bacteria. SSD acts via disrupting microbial cell membranes and cell walls; this differs from the antibacterial actions of silver nitrate or sodium sulfadiazine.

Suggested Dosages/Precautions/Adverse Effects

When used for burns SSD is applied once to twice daily at a thickness of approx. 1/16th of an inch. Dressings may be applied over the cream. When used for localized pyodermas once to twice daily treatment with the cream rubbed in is suggested.

Patients hypersensitive to sulfonamides may also react to SSD. Risks of continued treatment must be weighed against the risks of not treating with SSD. Patients with significant hepatic or renal dysfunction may accumulate drug, particularly when used over large areas.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Adverse effects associated with sulfonamides (e.g., KCS in dogs, blood dyscrasias in dogs/cats, etc) are possible particularly when used over large areas or for extended periods. Refer to the Sulfadiazine/Trimethoprim monograph in the main section of the reference for more information.

Veterinary-Labeled Silver Sulfadiazine Products

There are no topical products labeled for veterinary patients. An otic preparation (*Baytril Otic*®) contains SSD. See the otic section for more information.

Human-Labeled Silver Sulfadiazine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Silvadene ® (Hoechst MR)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 20, 50, 85, 400 & 1000 g.
SSD AF Cream ® (Boots)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 50, 400 & 1000 g.
Thermazene ® (Sherwood)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 50, 400 & 1000 g.
SSD Cream ® (Boots)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing cetyl alcohol, white petrolatum, stearyl alcohol, methylparaben. 25, 50, 85, 400 & 1000 g.

Antiseptics**CHLORHEXIDINE****(klor-heks-ih-deen)** Nolvasan®**Indications/Actions**

A topical antiseptic, chlorhexidine has activity against many bacteria, but apparently not predictably active against *Pseudomonas* or *Serratia* spp. It is available with veterinary labels in many different forms (solutions, shampoos, scrubs, ointments, sprays, etc).

Because it causes less drying and is usually less irritating than benzoyl peroxide, it is sometimes used in patients that cannot tolerate benzoyl peroxide. It does not have the keratolytic, degreasing or follicular flushing effects of benzoyl peroxide however. Chlorhexidine possesses some residual effects and can remain active on skin after rinsing.

At usual concentrations, chlorhexidine acts by damaging bacterial cytoplasmic membranes. Antifungal activity can be obtained with 2% or higher concentrations. For wound irrigation, 0.05–0.1% dilution in water is recommended.

Precautions/Adverse Effects

Keep away from eyes as chlorhexidine products can damage eyes. Clients should wash hands after application or wear gloves when applying. Safe in cats, although irritation and corneal ulcers have been reported.

Hypersensitivity and local irritant reactions are possible. Likelihood of irritation increases with increased concentrations. Chlorhexidine may retard wound healing; not recommended for long-term use particularly on granulating lesions.

Veterinary-Labeled Chlorhexidine Topical Products

There are also a several teat dip and udder wash products, a lubricant, and oral rinses are available. There are several trade names used for chlorhexidine products, including *Nolvasan*®, *Chlorhexiderm*®, *Dermachlor*®, *Chlorasan*®, *Chloradine*®, *Privasan*®, and *Chlorhex*®.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Chlorhexidine Spray (various manufacturers and trade names)	Spray: 4%	OTC (Vet)	Aloe. 8 oz. Shake well. Labeled for dogs, cats, & horses
Malaseb® Spray (DVM)	Spray: Miconazole nitrate 2% Chlorhexidine 2%	Rx (Vet)	Alcohol 30%. 8 oz. Labeled for use in dogs, cats, & horses.
Chlorhexidine Solution (various manufacturers and trade names)	Solution: 2%	OTC (Vet)	As the gluconate. 16 oz, 1 gal. May be labeled for use on dogs, horses, cattle and swine.
Chlorhexidine Concentrate (Davis)	Solution for dilution: 20%	OTC (Vet)	For 1%: Dilute 6 oz into 1 gal water or shampoo; for 2%: 12 oz into one gal.
Malaseb Pledgets® (DVM)	Pledget (medicated pad): 20 mg Chlorhexidine, 17.4 Miconazole	Rx (Vet)	Alcohol 30%. 60 per container. Labeled for use in dogs, cats, & horses.
Malaseb Towelettes® (DVM)	Towelette (medicated pad 6X6 inches): 72 mg Chlorhexidine, 63 mg Miconazole	Rx (Vet)	Polypropylene 60%, Alcohol 30%. 60 per container. Labeled for use in dogs, cats, & horses.
Chlorhexidine Flush (various manufacturers and trade names)	Flush: Depending on product concentration may not be not listed	OTC (Vet)	4, 12 oz
Malaseb® Flush (DVM)	Flush: Miconazole nitrate 2% Chlorhexidine 2%	OTC (Vet)	4, 12 oz.
Dermachlor Flush with Lidocaine® (Butler); Chlor-A-Cleans L® (Vedco)	Flush: Lidocaine 0.5% Chlorhexidine 0.2%	OTC (Vet)	Propylene glycol, malic acid, benzoic acid, salicylic acid, glycerin. 4 oz.
Chlorhexidine Ointment (various manufacturers and trade names)	Ointment: 1%	OTC (Vet)	1 & 7 oz, 1 lb.
DOUXO® Chlorhexidine PS (Sogeval)	Shampoo: Chlorhexidine 3% Phytosphingosine 0.05%	OTC (Vet)	Lipicid® C8G; 6.8 oz
Micro Pearls Advantage Seba-Hex Shampoo® (Evsco)	Shampoo: Chlorhexidine 2% Salicylic Acid 2% Sulfur 2%	Rx (Vet)	<i>Novasome</i> ® microvesicles. 12 oz, 1 gal. Labeled for dogs, cats and horses. Shake well; wear gloves.
Nolvasan Shampoo® (Fort Dodge)	Shampoo: 0.5%	OTC (DVM)	8 oz, 1 gal.
Chlorhexidine Shampoo 2% (various manufacturers and trade names)	Shampoo: 2%	OTC (Vet)	8, 16 oz, 1 gal
Hexadene® Shampoo (Virbac)	Shampoo: 3%	OTC (Vet)	With <i>Spherulites</i> ®. 8, 16 oz., 1 gal
Chlorhexidine Shampoo 4% (various manufacturers and trade names)	Shampoo: 4%	OTC (Vet)	12 oz.
Malaseb Shampoo® (DVM)	Shampoo: Miconazole nitrate 2% Chlorhexidine 2%	OTC (Vet)	8, 12 oz, 1 gal.
Ketochlor Shampoo (Virbac)	Shampoo: Ketoconazole 1% Chlorhexidine 2%	Rx (Vet)	8 oz. Approved for dogs and cats.
Malaseb® Concentrate Rinse (DVM)	Rinse: Miconazole nitrate 5.2% Chlorhexidine 5.9%	Rx (Vet)	8, 32 oz. Labeled for use on dogs, cats, horses. Must be diluted before use. Do not allow animal to lick the treated areas until dry.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Resichlor Leave-On Conditioner [®] (Virbac)	Conditioner: 2%	Rx (Vet)	8, 16 oz, 1 gal. Approved for dogs and cats.
Chlorhexidine Scrub (various)	Scrub: 2%, 4%	OTC (Vet)	1 gal.

Human-Labeled Chlorhexidine Topical Products

There are several topical skin cleansers available in the 2–4% range. Trade names include: *Hibiclens*[®], *Hibistar*[®], *Betasept*[®], *Exidine*[®], *Dyna-Hex*[®] and *BactoShield*[®].

ETHYL LACTATE

(*eth-il lak-tate*) Etiderm[®]

Indications/Actions

Ethyl lactate shampoo can be used when an antibacterial shampoo (bacteriostatic and bactericidal) is needed particularly in animals with surface and superficial pyoderma that cannot tolerate benzoyl peroxide. It also has keratoplastic effect, which provides anti-seborrheic activity.

A lipid soluble compound, ethyl lactate penetrates hair follicles and sebaceous glands where bacterial lipases convert it into lactic acid and ethanol, which are responsible for its antibacterial action. It is not as active as benzoyl peroxide against staphylococcal organisms, but is less irritating and drying.

Dosages/Precautions/Adverse Effects

Ethyl lactate shampoos are often used in conjunction with oral antibiotics and are usually used 2–3 times per week initially; frequency of use may be reduced when pyoderma is under control.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Adverse effects are unlikely, but local effects (erythema, pain, itching) are possible.

Veterinary-Labeled Ethyl Lactate Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Etiderm Shampoo [®] (Virbac)	Shampoo: 10% (in <i>Spherulite</i> [®] and free form)	OTC (Vet)	Chitosanide (in <i>Spherulite</i> [®] and free form), benzalkonium chloride (in encapsulated form), lactic acid, propylene glycol in a shampoo base. 8, 16 oz, 1 gal. Labeled for dogs and cats. Shake well.

Ethyl Lactate Topical Human-Labeled Products: None

POVIDONE IODINE

(*poe-vi-done eye-oh-dine*) Betadine[®]

Indications/Actions

An iodophore antiseptic, povidone iodine is rapidly bactericidal (against gram-positive and –negative bacteria) at low concentration. Also fungicidal and sporicidal (as a 1% aqueous solution). It is commonly used as a topical pre-surgical skin cleaner/antiseptic, but is infrequently used in small animal dermatology due to its drying, irritating and staining effects.

Povidone acts by slowly releasing iodine to tissues. Indicated for superficial pyoderma and *Malassezia* dermatitis.

Precautions/Adverse Effects

Povidone may be drying, irritating and staining to skin, hair and fabrics. Use with emollients may alleviate the drying effects. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Systemic absorption can result in renal and thyroid dysfunction.

Veterinary-Labeled Povidone Iodine Topical Products

There are several trade names used for povidone iodine products, including *Poviderm*[®], *Prodine*[®], *Vetadine*[®], *Betadine*[®], *Lanodine*[®], *Viodine*[®] and *Povidine*[®]. There are also (not listed) hoof dressings, teat dips, and udder washes available that contain povidone iodine.

Note: 10% povidone iodine yields 1% titratable iodine and so forth. Labels may be confusing.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Povidone Medicated Shampoo ® (Butler)	Shampoo: 5%	OTC (Vet)	8 oz, 1 gal.
Viodine Medicated Shampoo ® (Farnam)	Shampoo: 5%	OTC (Vet)	1 pt.
Iodine Shampoo (Evsco)	Shampoo: 2%	Rx (Vet)	12 oz. Not for use on cats or kittens.
Povidone Iodine Solution (various manufacturers and trade names)	Solution: 10%	OTC (Vet)	1 qt, 1 gal
Povidone Iodine Ointment (various manufacturers and trade names)	Ointment: 10%	OTC (Vet)	1 lb.
Povidone Iodine Surgical Scrub (various manufacturers and trade names)	Scrub: 7.5%	OTC (Vet)	1 gal

Human-Labeled Povidone Iodine Topical Products

There are several trade names used for povidone iodine products, including *Betadine*®, *Betagen*®, *Biodine*®, *Etodine*®, *Mallisol*®, *Minidyne*®, *Polydine*® and *Povidine*®. There are also (not listed) vaginal gels, swabs, and foaming skin cleansers available.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Povidone Iodine Solution (various manufacturers and trade names)	Solution: 10%	OTC (Human)	15, 30, 120 mL, 1 pt, 1 qt, 1 gal
Povidone Iodine Spray (various manufacturers and trade names)	Spray: 10% Aerosol: 5%	OTC (Human) OTC (Human)	30, 60 mL, 1 pt, 1 gal 89 mL
Povidone Iodine Surgical Scrub (various manufacturers and trade names)	Scrub: 5.5 – 7.5%	OTC (Human)	15 mL, 1 pt, 1 gal
Povidone Iodine Ointment (various manufacturers and trade names)	Ointment: 10%	OTC (Human)	1 g pkts, 30, 120 g, 1 lb.

TRICLOSAN (IRGASAN)

(trye-*k*lose-san)

Indications/Actions

Found in several products, often with other active ingredients, triclosan's antibacterial effects may be useful in treating superficial pyodermas.

Triclosan is a bis-phenol disinfectant/antiseptic. It has a activity against a wide range of organisms, including both gram-positive and gram-negative bacteria and acts via inhibiting bacterial fatty acid synthesis leading to disruption of cell membrane integrity. Triclosan reportedly is not effective against *Pseudomonas* spp. and may be less effective against staphylococci than either chlorhexidine or ethyl lactate.

Precautions/Adverse Effects

Triclosan should not be used on burned or denuded skin, or mucous membranes. Avoid contact with eyes.

Triclosan is not recommended as a surgical scrub. Clients should wash hands after application or wear gloves when applying. Allergic contact reactions may occur.

Veterinary-Labeled Triclosan Products

There are also triclosan products labeled for use as teat sealants (*Uddergold Dry*®) in cattle.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Sebalyt Shampoo ® (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC (Vet)	8, 12 oz, 1 gal.
Seborex Shampoo ® (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 3%	OTC (Vet)	8, 12 oz, 1 gal.
Triclosan Shampoo (Davis)	Shampoo: % not listed	OTC (Vet)	12 oz, 1 gal.

Human-Labeled Triclosan Topical Products

There are triclosan products labeled as hand, face or body washes for humans. Trade names include *Septi-Soft*®, *Septisol*®, *Clearasil Daily Face Wash*®, *Stridex Face Wash*®, *no more germs*®, *Oxy RESiDon't*®, and *ASC Lotionized*®.

Antifungal Agents

CLOTRIMAZOLE, TOPICAL

(kloe-trye-ma-zole) Lotrimin®

Indications/Actions

Topical clotrimazole has activity against dermatophytes and yeasts; it may be useful for localized lesions associated with *Malassezia*. It is not very effective in treating dermatophytosis in cats.

Clotrimazole inhibits the biosynthesis of ergosterol, a component of fungal cell membranes leading to increased membrane permeability and probable disruption of membrane enzyme systems.

Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible, but unlikely to occur.

Clotrimazole Topical Veterinary-Labeled Products

Note: There are several products containing clotrimazole for otic use; refer to that section for more information.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Clotrimazole Solution (Vet Solutions, Butler, Vedco)	Solution: 1%	Rx (Vet)	30 mL.

Clotrimazole Topical Human-Labeled Products

In addition to the products listed below, there vaginal creams and suppositories, and oral 10 mg troches.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Clotrimazole (various); Cruex ® (Novartis); Lotrimin AF ® (Schering-P); Desenex ® (Novartis)	Solution: 1%	OTC/Rx (Human). Status determined by labeling	Depending on product: 105 – 113 mL.
Lotrimin AF ® (Schering-P);	Lotion: 1%	OTC (Human)	20 mL.
Clotrimazole & Betamethasone Diprop. (Fougera) Lotrisone ® (Schering)	Lotion: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	30 mL.
Clotrimazole (various); Lotrimin AF ® (Schering-P);	Cream: 1%	OTC/Rx (Human). Status determined by labeling	Depending on product: 10, 30 mL.
Clotrimazole & Betamethasone Diprop. (Fougera) Lotrisone ® (Schering)	Cream: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	15, 45 g.

ENILCONAZOLE

(ee-nil-kon-a-zole)

Indications/Actions

Although no dosage forms are currently commercially available for topical use in the USA, Enilconazole is used topically for treating dermatophytosis in small animals and horses using compounded products. A commercially available topical rinse *Imaverol*® (Janssen) 10% is available with canine, bovine and equine use labeling in many countries. Intranasal instillation of enilconazole after plaque debridement has also been shown useful in treating nasal aspergillosis in small animals.

Use of topical enilconazole on cats with dermatophytosis is somewhat controversial as there are apparently no products with feline labeling available in Europe or Canada. There are preliminary reports of safely and successfully using enilconazole on dermatophytic cats in combination with oral itraconazole.

A topical product and a poultry environmental disinfectant product (*Clinafarm EC*®) is available in the USA. It is technically illegal to use this product other than it is labeled; it is an EPA licensed product in the USA.

Precautions/Adverse Effects

Avoid contact with eyes. Clients should wear gloves when applying and use eye protection.

When used topically in cats, hypersalivation, vomiting, anorexia/weight loss, muscle weakness, and a slight increase in serum ALT levels have been reported.

Enilconazole Topical Veterinary-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Imaverol ® (Janssen)	Concentrate: 10%	Not available in USA	100 mL. Concentrate is diluted to 0.2% (1 part concentrate to 50 parts water). For Dogs: Dilute as directed and wash 4 times, at 3–day intervals; may also use as dip.
Clinafarm EC ® (Schering Plough)	Emulsifiable Concentrate: 13.8%	OTC (Vet) EPA Pesticide	750 mL. Labeled for the control of <i>Aspergillus fumigatus</i> contamination in poultry hatchery equipment. It is a violation of US Federal Law to use this product in a manner inconsistent with its labeling. Corrosive; may cause irreversible eye damage. Labeling includes several warnings on ingestion or exposure.

Enilconazole Topical Human-Labeled Products: None

KETOCONAZOLE, TOPICAL

(kee-toe-kah-na-zole) Nizoral®, Ketochlor®

For systemic use, see the monograph found in the main section

For otic use, see the otic appendix

Indications/Actions

Topical ketoconazole has activity against dermatophytes and yeasts and ketoconazole shampoos can be effective treatment for *Malassezia* dermatitis. Patients with severe, generalized infections may require additional systemic therapy. Topical ketoconazole shampoos are generally ineffective (or minimally effective) when used alone for dermatophytosis.

Suggested Dosages/Precautions/Adverse Effects

Labeled directions for the veterinary shampoo (*Ketochlor*®) are: may initially be used 2–3 times a week for 4 weeks and then reduced to once a week, or as directed by the veterinarian.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible.

Ketoconazole Topical Veterinary-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Ketochlor Shampoo ® (Virbac)	Shampoo: Ketoconazole 1% Chlorhexidine 2%	Rx (Vet)	8 oz. Approved for dogs and cats.

Ketoconazole Topical Human-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Nizoral A-D ® (McNeil)	Shampoo: 1%	OTC (Human)	207 mL.
Nizoral ® (McNeil)	Shampoo: 2%	Rx (Human)	Aqueous suspension. 120 mL.
Ketoconazole (Clay-Park)	Shampoo: 2%	Rx (Human)	118 mL.
Ketoconazole (Teva)	Cream: 2%	Rx (Human)	Aqueous vehicle containing cetyl alcohol, stearyl alcohol, sodium sulfite. 15, 30 60 g.
Nizoral ® (McNeil)	Cream: 2%	Rx (Human)	15, 30, 60 g.

LIME SULFUR (SULFURATED LIME SOLUTION)

(lime sul-fur) Lymdyp®

Indications/Actions

Lime sulfur applications are effective and relatively inexpensive, albeit an unaesthetic treatment for *Malassezia* dermatitis or dermatophytosis. Also recommended for treatment of surface demodicosis (*Demodex gato*) in cats, Cheyletiellosis, chiggers, *Sarcoptes* and notoedric mange, fur mites and lice. Because of the negatives associated with its application, lime sulfur use is generally limited to those cases that have generalized infections that do not respond to shampoo therapy alone and when systemic therapy is too costly to pursue. Lime sulfur treatments can also be useful in the adjunctive treatment of demodectic or sarcoptic mange.

Lime sulfur has antibacterial and antifungal (and some anti-yeast) properties secondary to the formation of pentathionic acid and hydrogen sulfide after application. Both lime sulfur and enilconazole are thought to have the most topical activity against *M. canis*. Lime sulfur may also have keratolytic, keratoplastic, antiparasitic, and antipruritic effects.

Suggested Dosages/Precautions/Adverse Effects

Labeled dose for *LymDyp*®: Shake well; dilute 4 oz. in one gal of water. Apply as a rinse or dip at 5–7 day intervals. Do not rinse. For more chronic or resistant cases, may be used at 8 oz per gallon.

Labeled dose for *LimePlus Dip*®: Pour 4 ounces of contents into a gallon container and fill with water. Mix well. Bathe animal prior to application. Rinse off shampoo. Pour entire contents of diluted *LimePlus Dip*® onto pet and work into skin. Allow to dry on the animal. Do not rinse. May be applied at 5 to 7 day intervals.

When used for dermatophytosis, twice weekly treatments have been recommend, if patients can tolerate the treatment's irritating effects.

Avoid contact with eyes. Can stain porous surface (e.g., concrete, porcelain) or permanently discolor jewelry. Clients should wear gloves and protect skin and eyes from solution. Application should be performed in a well-ventilated area or clients should wear a protective (respirator-type) mask.

While reasonably non-toxic, lime sulfur may cause skin irritation or drying. Adding mineral oil to the solution may reduce its drying effects. Lime sulfur can stain (temporarily) light colored fur. Lime sulfur's odor may persist on treated animals, but generally is tolerable once the patient dries. Oral ingestion can cause nausea and oral ulcers, mainly in cats; an Elizabethan collar may help prevent this from occurring.

Veterinary-Labeled Lime Sulfur Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
<i>LymDyp</i> ® (DVM)	Concentrate: 76.9%	OTC (Vet)	16 oz, 1 gal. Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above).
<i>LimePlus Dip</i> ® (Dermapet)	Concentrate: 97.8%	OTC (Vet)	4, 16 oz., 1 gal. Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above).

Human-Labeled Lime Sulfur Topical Products: None

MICONAZOLE, TOPICAL

(mye-kah-nah-zole)

Indications/Actions

Topical miconazole has activity against dermatophytes and yeasts; miconazole shampoos can be effective treatment for *Malassezia* dermatitis. Patients with severe, generalized infections may require systemic therapy. Lotions, sprays and creams are generally used for localized lesions associated with *Malassezia* or dermatophytes. See otic section for information on application for *Malassezia* otitis externa.

Topical miconazole products are generally ineffective (or minimally effective) when used alone for dermatophytosis; adjunctive systemic treatment is usually required.

Miconazole's actions are a result of altering permeability of fungal cellular membranes and interfering with peroxisomal and mitochondrial enzymes, leading to intracellular necrosis. Miconazole products are fungicidal with repeated application.

Suggested Dosages/Precautions/Adverse Effects

Topical creams, lotions or sprays are applied to localized lesions, usually twice daily. Shampoos need a contact time of at least 10 minutes for efficacy; they are usually recommended for use at least twice weekly.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible, but unlikely to occur, but in very inflamed, eroded to ulcerated skin, the pledgets, towelettes, spray containing alcohol (*Malaseb*®) can be severely irritating.

Veterinary-Labeled Miconazole Topical Products

Note: Miconazole nitrate is the salt generally used in pharmaceutical products. While technically, a 1% concentration of miconazole nitrate contains less than 1% miconazole, the following products are rounded to the closest full percent regardless of how much miconazole base is actually in each product.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
<i>Micro-Pearls Advantage Miconazole 1% Spray</i> ® (Evsco)	Spray: 1%	Rx (Vet)	4 oz. Labeled for dogs, cats, horses.
<i>Miconosol Spray</i> ® 1%	Spray: 1%	Rx (Vet)	120, 240 mL. Labeled for use on dogs and cats.
<i>Conofite Spray</i> ® 1% (Schering-Plough)	Spray: 1%	Rx (Vet)	60 mL. Labeled for use on dogs and cats.
<i>Micaved Spray</i> ® 1% (Vedco)	Spray: 1%	Rx (Vet)	60 mL. Labeled for use on dogs and cats.
<i>Malaseb</i> ® Spray (DVM)	Spray: Miconazole nitrate 2% Chlorhexidine 2%	OTC (Vet)	Alcohol 30%. 8 oz. Labeled for use in dogs, cats, & horses.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Micazole Spray® (Butler)	Spray: 1%	Rx (OTC)	120, 240 mL. Labeled for use on dogs and cats.
Malaseb® Flush (DVM)	Flush: Miconazole nitrate 2% Chlorhexidine 2%	OTC (Vet)	4, 12 oz. Labeled for use on dogs and cats.
Malaseb® Concentrate Rinse (DVM)	Rinse: Miconazole nitrate 5.2% Chlorhexidine 5.9%	Rx (Vet)	8, 32 oz. Labeled for use on dogs, cats, horses. Must be diluted before use. Do not allow animal to lick the treated areas until dry.
Malaseb® Pledgets (DVM)	Pledget (medicated pad): 17.4 Miconazole 20 mg Chlorhexidine	OTC (Vet)	Alcohol 30%. 60 per container. Labeled for use in dogs, cats, & horses.
Conofite Cream® 2% (Schering-Plough)	Cream: 2%	Rx (Vet)	15 g. Labeled for use on dogs and cats.
Resizole Leave-On Lotion® (Virbac)	Lotion: 2%	Rx (Vet)	8 oz. Labeled for use on dogs and cats.
Miconosol Lotion 1%® (Med-Pharmex)	Lotion: 1%	Rx (Vet)	60 mL. Labeled for use on dogs and cats.
Conofite Lotion® 1% (Schering-Plough)	Lotion: 1%	Rx (Vet)	30 mL. Labeled for use on dogs and cats.
Micaved Lotion® 1% (Vedco)	Lotion: 1%	Rx (Vet)	60 mL. Labeled for use on dogs and cats.
Micazole Lotion® 1% (Butler)	Lotion: 1%	Rx (Vet)	60 mL. Labeled for use on dogs and cats.
Sebazole® Shampoo (Vet Solutions)	Shampoo: Miconazole nitrate 2%, Chlorxylenol 1%	Rx (Vet)	Salicylic acid, sodium thiosulfate. 8, 12 oz, 1 gal. Labeled for dogs, cats, and horses.
Micro-Pearls Advantage Miconazole 1% Shampoo® (Virbac)	Shampoo: 1%	Rx (Vet)	Novasome® microvesicles. 12 oz. Labeled for dogs, cats, and horses.
Dermazole Shampoo® (Virbac)	Shampoo: 2%	Rx (Vet)	6, 16 oz. Labeled for use on dogs and cats.
Malaseb Shampoo® (DVM)	Shampoo: Miconazole nitrate 2% Chlorhexidine 2%	OTC (Vet)	8, 12 oz, 1 gal. Labeled for dogs, cats, and horses.

Human-Labeled Miconazole Topical Products

In addition to the products listed below, there are 2% topical vaginal creams, vaginal suppositories, 2% powders and spray powders available. Most human-labeled products are OTC.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Micatin® (Ortho); Neosporin AF® (Pfizer); Lotrimin AF® (Schering); Prescription Strength Desenex® (Ciba)	Spray (liquid): 2%	OTC (Human)	Depending on product: 105 – 113 mL.
Tetterline® (SSS Co.)	Ointment: 2%	OTC (Human)	28.4 g.
Zeosorb-AF® (Stiefel)	Gel: 2%	OTC (Human)	24 g.
Miconazole Nitrate (Taro); Micatin® (Ortho); Monistat-Derm® (Ortho); Neosporin AF® (Pfizer)	Cream: 2%	OTC (Human)	Depending on product: 15, 30, 90 g..

NYSTATIN

(nye-sta-tin)

For systemic use, see the monograph found in the main section.

Indications/Actions

Because of limited dosage forms and other alternative antiyeast medications readily available, nystatin is not usually used alone in small animal medicine. The combination products (Panalog et al) can be useful for topical lesions caused by yeasts or yeast-like organisms; they have been used for mixed otitis infections for many years.

Nystatin has efficacy against many yeasts and yeast-like organisms (Malassezia). Its mechanism of action is believed secondary to binding to sterols in the fungal cell membranes thereby increasing membrane permeability with leakage of intracellular components. Nystatin does not have activity against bacteria and is ineffective against other fungi.

Precautions/Adverse Effects

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying

Nystatin alone is very safe, although hypersensitivity reactions are possible. The combination veterinary products are usually well tolerated when used on skin. Neomycin can cause localized sensitivity.

Veterinary-Labeled Nystatin-Containing Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Panalog Cream ® (Fort Dodge) Cortalone Cream ® (Vedco) Derma-Vet Cream ® (Med-Pharmex)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx (Vet)	Aqueous vanishing cream. 7.5, 15 g. Labeled for use in dogs or cats.
Panalog Ointment ® (Fort Dodge) Animax Ointment ® (Pharmaderm) Quadratop Ointment ® (Butler) Derma-Vet Ointment ® (Med-Pharmex) Dermalog Ointment ® (RXV) Dermalone Ointment ® (Vedco)	Ointment: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx (Vet)	7.5, 15, 30, 240 mL. Labeled for use in dogs or cats.

Human-Labeled Nystatin Topical Products

In addition to the products listed below, there are vaginal tablets and oral products. Oral products are found in the main section.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Nystatin (various) Mycostatin ® (Westwood Squibb) Nilstat ® (Lederle) Nystop ® (Paddock) Pedi-Dri ® (Pedinol)	Powder: 100,000 units/g	Rx (Human)	Depending on product: 15, 30, 60 g.
Nystatin (various) Mycostatin ® (Westwood Squibb) Nilstat ® (Lederle)	Ointment: 100,000 units/g	Rx (Human)	Depending on product: 15, 30 g.
Nystatin-Triamcinolone Acetonide (various) Mycogen II ® (Goldline) Mycolog-II ® (Bristol Meyers Squibb) Myco-Triacet II ® (Lemmon)	Ointment: Nystatin 100,000 units/g Triamcinolone Acet. 0.1%	Rx (Human)	Depending on product: 15, 30, 60, 120 g.
Nystatin (various) Mycostatin ® (Westwood Squibb) Nilstat ® (Lederle)	Cream: 100,000 units/g	Rx (Human)	Depending on product: 15, 30, 240 g.
Nystatin-Triamcinolone Acetonide (various) Mycogen II ® (Goldline) Mycolog-II ® (Bristol Meyers Squibb) Myco-Triacet II ® (Lemmon) Myconel ® (Marnel)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 0.1%	Rx (Human)	Depending on product: 1.5 g. pkts, 15, 30, 60, 120 g.
Myco-Biotic II ® (Moore)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 0.1% Neomycin Sulf. 0.5%	Rx (Human)	Aqueous vanishing cream w/ white petrolatum. 15, 30, 60, 454 g.

SELENIUM SULFIDE

(si-*leen*-ee-um *sul*-fide)

Indications/Actions

Selenium sulfide may be useful in seborrheic disorders (mainly for seborrhea oleosa) and for adjunctive treatment of *Malassezia* dermatitis, particularly in dogs exhibiting signs of waxy, greasy or scaly (seborrheic) dermatitis. There may be some residual activity on the skin.

Selenium sulfide possesses antifungal (including sporicidal activity), keratolytic, keratoplastic and degreasing properties. It affects cells of the epidermis and follicular epithelium (alters the epidermal turnover) and interferes with hydrogen bond formation of keratin thereby reducing corneocyte production. Selenium sulfide's antifungal mechanism of action is not well understood.

Precautions/Adverse Effects

Selenium sulfide products should **not be used on cats**. Avoid contact with eyes; selenium sulfide can discolor jewelry. Clients should wear gloves when using.

Selenium sulfide can be irritating, cause excessive drying and fur staining. Mucous membranes and scrotal areas may be particularly sensitive to the irritating effects of the drug. A rebound seborrhea may occur where signs not only recur after discontinuation, but worsen.

Veterinary-Labeled Selenium Sulfide Products

There apparently are no labeled veterinary products containing selenium sulfide currently available in the USA; Seleen® may be available in other countries.

Human-Labeled Selenium Sulfide Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Selenium Sulfide (various)	Shampoo/Lotion: 1%	OTC (Human)	210 mL.
Selsun Blue Medicated Treatment® (Chattem)	Shampoo/Lotion: 1%	OTC (Human)	Menthol. 325 mL/
Head & Shoulders Intensive Treatment® (P&G)	Shampoo/Lotion: 1%	OTC (Human)	400 mL.
Selenium Sulfide (various)	Lotion: 2.5%	Rx (Human)	120 mL.
Selsun® (Abbott)	Lotion: 2.5%	Rx (Human)	120 mL.

TERBINAFINE HCL**(TOPICAL)**

(ter-*bin*-a-feen) Lamisil®

For systemic use, see the monograph found in the main section

Indications/Actions

An allylamine antifungal agent, terbinafine may be useful for localized lesions associated with *Malassezia*. With its current topical dosage forms, it does not appear to be very useful for treating dermatophytosis in cats.

Terbinafine inhibits the biosynthesis of ergosterol, but its mechanism for inhibiting ergosterol is different from the azole antifungals. a component of fungal cell membranes leading to increased membrane permeability and probable disruption of membrane enzyme systems. Terbinafine is fungicidal against dermatophytes, but may only be fungistatic against yeasts.

Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible, but unlikely to occur.

Veterinary-Labeled Terbinafine Topical Products: None**Human-Labeled Terbinafine Topical Products**

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Lamisil AT® (Novartis)	Cream: 1%	OTC (Human)	15, 30 g
DesenexMax® (Novartis); generic	Cream: 1%	OTC (Human)	24 g
Lamisil AT® (Novartis)	Spray: 1%	OTC (Human)	Ethanol, propylene glycol. 6 & 12 g
Lamisil AT® (Novartis)	Gel: 1%	OTC (Human)	Ethanol, benzyl alcohol. 30 mL.

Keratolytic Agents

See also the Benzoyl Peroxide monograph listed in the Antibacterial section

SALICYLIC ACID

(sal-i-sil-ic ass-id)

Indications/Actions

Often combined with sulfur, salicylic acid shampoos are often employed to treat patients with seborrheic disorders (seborrhea sicca and oleosa) exhibiting mild to moderate scaling, with mild waxy and keratinous debris. In higher concentrations, topicals such as *Kerasolv*[®] Gel (6.6% salicylic acid) can be used to remove localized excessive tissues associated with hyperkeratotic disorders, such as calluses and idiopathic thickening of the planum nasale and footpads.

Salicylic acid has mildly antipruritic, antibacterial (bacteriostatic), keratoplastic and keratolytic actions. Lower concentrations are primarily keratoplastic and higher concentrations, keratolytic. Salicylic acid lowers skin pH, increases corneocyte hydration and dissolves the intercellular binder between corneocytes. Salicylic acid and sulfur are thought to be synergistic in their keratolytic actions.

Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Burning, itching, pain, erythema, swelling can occur from salicylic acid, particularly when used in higher concentrations (> 2%). A rebound seborrheic effect can occur when using shampoo products containing sulfur.

Veterinary-Labeled Salicylic Acid Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Kerasolv Gel [®] (DVM)	Gel: 6.6%	OTC (Vet)	30 mL. Labeled for use on dogs, cats, horses. Other ingredients (humectants): sodium lactate and urea, propylene glycol. Rub in well. Usually used once daily initially, may reduced to 2–3 times per week once remission occurs. Often requires life-long treatment.
Sebalyt Shampoo [®] (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC (Vet)	8, 12 oz, 1 gal.
Seborex Shampoo [®] (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 3%	OTC (Vet)	8, 12 oz, 1 gal.
Nova Pearls Medicated Dandruff Shampoo [®] (Tomlyn)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	<i>Novasome</i> [®] moisturizers. 12 oz, 1 gal.
Dermapet Dermasebs Shampoo [®] (Dermapet)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	8 oz, 1 gal
Keratolux Shampoo [®] (Virbac)	Shampoo: Salicylic Acid 1% Zinc Gluconate 0.5% Pyridoxine 0.5%	OTC (Vet)	<i>Spherulites</i> [®] , fatty acids, tea tree leaf oil. 8, 16 oz; 1 gal, Shake well; wear gloves.
Sebolux Shampoo [®] (Virbac)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	Chitosanide, urea, glycerin. Ingredients in free form and in <i>Spherulites</i> [®] . 8, 16 oz; 1 gal, Shake well; wear gloves.
Micro Pearls Advantage Seba-Moist Shampoo [®] (Evsco)	Shampoo: Salicylic Acid 2% Sulfur 2%	Rx (Vet)	<i>Novasome</i> [®] microvesicles. 12 oz, 1 gal. Labeled for dogs and cats. Shake well; wear gloves.
Micro Pearls Advantage Seba-Hex Shampoo [®] (Evsco)	Shampoo: Chlorhexidine 2% Salicylic Acid 2% Sulfur 2%	Rx (Vet)	<i>Novasome</i> [®] microvesicles. 12 oz, 1 gal. Labeled for dogs, cats and horses. Shake well; wear gloves
NuSal-T [®] (IVX)	Shampoo: Salicylic acid 3%, Coal Tar 2%, menthol 1%	OTC (Human)	Labeled for dogs; in 237 mL, 355 mL & 3.78 L

Human-Labeled Salicylic Acid Topical Products

Note: There are many topical salicylic acid products labeled for human use, including topical creams, ointments, transdermal patches, liquids and gels that are principally labeled for wart removal. Except for one product (*Salex*®; 6% cream), they are available OTC. There are also many OTC skin cleansers and shampoos containing salicylic acid and usually sulfur (sometimes coal tar or menthol). As there are several similar products formulated and labeled for animal use, human products will not be listed. For more information on these products, refer to a comprehensive human drug reference or contact a pharmacist.

SULFUR, PRECIPITATED

(sul-fer)

Indications/Actions

Often combined with salicylic acid, sulfur-containing shampoos are often employed to treat patients with seborrheic disorders exhibiting mild to moderate scaling, with mild waxiness and keratinous debris.

Sulfur has keratoplastic and keratolytic actions. Lower concentrations of sulfur are primarily keratoplastic secondary to assisting conversion of cysteine to cystine, thought an important factor in the maturation of corneocytes. Like salicylic acid, sulfur's keratolytic effects increase with concentration. Salicylic acid and sulfur are believed synergistic in their keratolytic actions. Sulfur also has mild degreasing effects and can be mildly antipruritic.

Sulfur also has antibacterial, antifungal, and antiparasitic effects secondary to sulfur conversion to hydrogen sulfide and pentathionic acid by bacteria and keratocytes.

Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Sulfur can be drying, can cause pruritus and be irritating. Residual odor is often bothersome to clients. Sulfur may stain fabrics and hair. A rebound seborrheic effect can occur when using shampoo products containing sulfur.

Veterinary-Labeled Sulfur Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Sebalyt Shampoo ® (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC (Vet)	8, 12 oz, 1 gal.
Seborex Shampoo ® (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 3%	OTC (Vet)	8, 12 oz, 1 gal.
Micro Pearls Advantage Seba-Hex Shampoo ® (Evsco)	Shampoo: Chlorhexidine 2% Salicylic Acid 2% Sulfur 2%	Rx (Vet)	<i>Novasome</i> ® microvesicles. 12 oz, 1 gal. Labeled for dogs, cats and horses. Shake well; wear gloves.
Micro Pearls Advantage Seba-Moist Shampoo ® (Evsco)	Shampoo: Salicylic Acid 2% Sulfur 2%	Rx (Vet)	<i>Novasome</i> ® microvesicles. 12 oz, 1 gal. Labeled for dogs and cats. Shake well; wear gloves.
Sebolux Shampoo ® (Virbac)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	Chitosanide, urea, glycerin. Ingredients in free form and in <i>Spherulites</i> ®. 8, 16 oz; 1 gal, Shake well; wear gloves.
Keratolux Shampoo ® (Virbac)	Shampoo: Salicylic Acid 1% Zinc Gluconate 0.5% Pyridoxine 0.5%	OTC (Vet)	<i>Spherulites</i> ®, fatty acids, tea tree leaf oil. 8, 16 oz; 1 gal, Shake well; wear gloves.
Dermapet Dermasebs Shampoo ® (Dermapet)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	8 oz, 1 gal
Nova Pearls Medicated Dandruff Shampoo ® (Tomlyn)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC (Vet)	<i>Novasome</i> ® moisturizers. 12 oz, 1 gal.
Paraguard Shampoo ® (First Priority)	Shampoo: Captan 2% Sulfur 1%	OTC (Vet)	32 oz. Labeled as an anti-ringworm, antifungal, antibacterial shampoo for dogs, cats & horses.
Sulf OxyDex Shampoo ® (DVM)	Shampoo: Benzoyl peroxide 2.5% Sulfur (micronized) 2%	Rx (Vet)	8, 12 oz, 1 gal.

Human-Labeled Sulfur Topical Products

Note: There are several topical products containing sulfur labeled for human use, including topical creams, lotions, shampoos, soaps and masks that are principally labeled for acne or dandruff. For more information on these products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

COAL TAR

(*kole tar*)

Note: At the time of writing, many veterinary-labeled coal tar products have been withdrawn from the market due to concerns that coal tar may be carcinogenic. This action does not appear to be a FDA-mandate, but a voluntary withdrawal from the marketplace.

Indications/Actions

Use of coal tar containing shampoos in veterinary medicine is somewhat controversial, particularly since all veterinary-labeled products have been withdrawn from the market. However, coal tar shampoos have been used in dogs for treating greasy dermatoses (seborrhea oleosa) for many years.

Coal tar possesses keratoplastic, keratolytic, vasoconstrictive, antipruritic and degreasing actions. Coal tar's mechanism of keratoplastic (keratoregulating) action is probably secondary to decreasing mitosis and DNA synthesis of basal epidermal cells.

Precautions/Adverse Effects

The carcinogenic risks associated with coal tar products are hotly debated. At present, most (including the FDA) believe that coal tar products with concentrations of 5% or less are safe for human use. However, should they be used on animals, clients should wear gloves when applying and wash off any product that contacts their skin. Carcinogenic risk assessment for dogs using coal tar products was not located.

Coal tar products should **not be used on cats**, patients who have prior sensitivity reactions to tar products or have dry scaling dermatoses.

Be careful in comparing coal tar concentrations on labels. Coal tar solution contains approximately 20% coal tar extract or refined tar. For example, a 10% coal tar solution contains approximately 2% coal tar (refined).

Photosensitization, skin drying and skin irritation are possible with tar therapy. Adverse effects are more likely with tar concentrations greater than 3%. Residual odor is often bothersome to clients. Tar may stain fabrics or haircoats and discolor jewelry.

Veterinary-Labeled Coal Tar-Containing Products

Product (Company)	Form: Concentration (Concentrations listed as re-fined tar or extract)	Label Status	Other Ingredients; Size(s)
NuSal-T® (IVX)	Shampoo: Coal Tar 2%, Salicylic acid 3%, menthol 1%	OTC (Human)	Labeled for dogs; in 237 mL, 355 mL & 3.78 L

Human-Labeled Coal Tar-Containing Topical Products

Product (Company)	Form: Concentration (Concentrations listed as refined tar or extract)	Label Status	Other Ingredients; Size(s)
DHS Tar® (Person & Covey)	Shampoo 0.5% Coal Tar	OTC (Human)	Liquid available in 120, 240 & 480 mL. Gel: 240 g.
Tera-Gel® (Geritrex)	Shampoo: 0.5% Coal Tar	OTC (Human)	
PC-Tar® (Geritrex)	Shampoo: 1% Coal Tar	OTC (Human)	180 mL. 114 mL.
Zetar® (Dermik)	Shampoo: 1% Coal Tar	OTC (Human)	177 mL.
Doak Tar® (Doak)	Shampoo: 1.2% Coal Tar	OTC (Human)	Isopropyl alcohol. 237 mL.
Ionil T Plus® (Healthpoint)	Shampoo: 2% Coal Tar	OTC (Human)	120, 240 mL.
Neutrogena T/Gel Original® (Neutrogena)	Shampoo: 2% Coal Tar extract	OTC (Human)	132, 255, 480 mL.
Pentrax® (Medicis)	Shampoo: 5% Coal Tar	OTC (Human)	236 mL.
Creamy Tar® (Genisis)	Shampoo: 2% Coal Tar	OTC (Human)	240 mL.
MG 217 Medicated Tar® (Triton)	Shampoo: 3% Coal Tar	OTC (Human)	120, 240 mL.
Polytar® (Stiefel)	Shampoo: equiv to 0.5% Coal Tar	OTC (Human)	Lanolin. 177, 355 mL.

- Salicylic Acid, Sulfur and Coal Tar monographs in the Keratolytics section

PHYTOSPHINGOSINE

(fye-tos-*fin*-joe-seen) DOUXO®

Indications/Actions

Phytosphingosine is a unique topical antiseborrheic compound. It is in a class called ceramides which are waxy materials meant to mimic the normal lipid composition of the stratum corneum. It may also have some antiinflammatory and antimicrobial properties.

Suggested Dosages/Precautions/Adverse Effects

See the labeled direction for each product.

No specific precautions or adverse effects were located for these products.

Phytosphingosine Topical Veterinary-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
DOUXO® Seborrhea Shampoo (Sogeval)	Shampoo: Phytosphingosine 0.1%	OTC (Vet)	Fomblin (stabilizer), cationic conditioners; 6.8 oz
DOUXO® Chlorhexidine PS (Sogeval)	Shampoo: Chlorhexidine 3% Phytosphingosine 0.05%	OTC (Vet)	<i>Lipicid</i> ® C8G; 6.8 oz
DOUXO® Seborrhea MicroEmulsion Spray (Sogeval)	Spray: Phytosphingosine 0.2%	OTC (Vet)	<i>Boswellia serrata</i> extract, glycerin; 6.8 oz
DOUXO® Seborrhea Spot-on (Sogeval)	Spot-on Solution: Phytosphingosine 1%	OTC (Vet)	Transcutol (surface diffuser)

Phytosphingosine Topical Human-Labeled Products: None

Immunomodulators, Topical

IMIQUIMOD

(TOPICAL)

(imi-i-*kwi*-mod) Aldara®

Indications/Actions

An immune response modifier, imiquimod may be useful in the treatment of a variety of topical conditions in animals. It is labeled for use on humans as a treatment for genital or perianal warts, superficial basal cell carcinomas and actinic keratoses of the face and scalp. In dogs and cats, imiquimod potentially may be of benefit in treating feline herpes virus dermatitis, actinic keratosis, squamous cell carcinoma and Bowen's disease, papillomas virus lesions, and localized solar dermatitis or solar carcinoma *in situ*. In horses, imiquimod has been anecdotally used with success in treating sarcoids.

Imiquimod stimulates the patient's own immune system to release a variety of cytokines including interferon-alpha and interleukin-12. Imiquimod itself does not have *in vitro* activity against wart viruses, but stimulates monocytes and macrophages to release cytokines that induce a regression in viral protein production.

Suggested Dosages/Precautions/Adverse Effects

Use in animals is still rather limited and ongoing research on this agent is being performed. Doses and treatment regimens are still being determined; they will most likely vary depending on the lesion treated. At present, dosing ranges from applying a thin film once daily to 2–3 times weekly.

Clients administering the drug should wear gloves when handling or applying the cream. It is advised to avoid getting in eyes or on mucous membranes; but dogs with oral mucosal papillomas have been treated without significant problems. While there are low chances the drug would be absorbed systemically, do not allow animal to groom/lick the applied site; occlusive dressings should not be used over the treatment site. Application site should not be touched after application. Avoid exposure of the site to sunlight as there are concerns there may be increased risks of sunburn after use (not proven).

Local skin reactions are common with imiquimod therapy and include application site reactions: erythema, burning, tenderness, pain, irritation, oozing/exudate and necrosis. Treatment duration and frequency may need to be adjusted depending on response and irritant reactions. Depigmentation and hair loss may occur at application sites as post-treatment sequelae.

Imiquimod Topical Veterinary-Labeled Products: None

Imiquimod Topical Human-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Aldara® (3M Pharm)	Cream: 5%	Rx (Human)	Cetyl alcohol, stearyl alcohol, white petrolatum, benzyl alcohol, parabens. Single use 250 mg packets in boxes of 12.

TACROLIMUS

(TOPICAL)

(ta-kroe-li-mus) Protopic®

Indications/Actions

Tacrolimus ointment may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo and for perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy). Unlike topical corticosteroids, tacrolimus or pimecrolimus do not have atrophogenic or metabolic effects associated with long-term or large area treatment.

Tacrolimus acts similarly as cyclosporine, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils.

Suggested Dosages/Precautions/Adverse Effects

Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled and then reduce application frequency to a level that controls inflammation, etc.

The commercially available ointment should not be used as, or compounded into an ophthalmic preparation for treating KCS in dogs as it contains propylene carbonate, a known ocular toxin. Both tacrolimus and pimecrolimus have FDA-mandated “black box” warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (e.g., a Q-tip) when applying the ointment.

Early reports are that topical tacrolimus is usually well tolerated in dogs, but localized irritation and pruritus have been reported in humans and dogs using the drug. Early anecdotal reports, state that pimecrolimus may be less irritating than tacrolimus in dogs, but also may not be quite as effective. The cost of the medication may be cost prohibitive for some clients.

Veterinary-Labeled Tacrolimus Topical Products: None

Human-Labeled Tacrolimus Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Protopic® (Astellas Pharma)	Ointment: 0.03, 0.1%	Rx (Human)	30, 60, 100 g.

PIMECROLIMUS

(TOPICAL)

(pim-e-kroe-li-mus) Elidel®

Indications/Actions

A relatively new addition to the human topical armamentarium, pimecrolimus cream may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo and for perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy). Unlike topical corticosteroids, tacrolimus or pimecrolimus do not have atrophogenic or metabolic effects associated with long-term or large area treatment.

Pimecrolimus acts similarly as cyclosporine and tacrolimus, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils. Pimecrolimus may not have identical mechanisms of action as tacrolimus, as it did not impair the primary immune response (as did tacrolimus) in mice after a contact sensitizer was applied. Both drugs did impair the secondary response however. Any clinical significance associated with this difference is not yet clear.

Suggested Dosages/Precautions/Adverse Effects

Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled and then reduce application frequency to a level that controls inflammation, etc.

Both tacrolimus and pimecrolimus have FDA-mandated “black box” warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (*e.g.*, a Q-tip) when applying the cream.

Early reports are that topical pimecrolimus is usually well tolerated in dogs, but localized irritation and pruritus have been reported in humans and dogs using the drug. Early anecdotal reports, state that pimecrolimus may be less irritating than tacrolimus in dogs, but also may not be quite as effective. The cost of the medication may be prohibitive for some clients.

Veterinary-Labeled Tacrolimus Topical Products: None

Tacrolimus Topical Human-Labeled Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
Elidel® (Novartis)	Cream: 1%	Rx (Human)	30, 60, 100 g.

Retinoids, Topical

TRETINOIN (TRANS-RETINOIC ACID; VITAMIN A ACID)

(*tret*-in-oyn) Retin-A®

Indications/Actions

Topical tretinoin may be useful in treating localized follicular or hyperkeratotic disorders such as acanthosis nigrans, idiopathic nasal and footpad hyperkeratosis, callous pyodermas, or chin acne. Tretinoin's exact mechanism of action is not well understood, but it stimulates cellular mitotic activity, increases cell turnover, and decreases the cohesiveness of follicular epithelial cells.

Suggested Dosages/Precautions/Adverse Effects

In small animals, topical tretinoin gel is usually used initially at a concentration of 0.05% and is applied once daily. Treatment continues as long as the animal tolerates the treatment or until controlled. Once controlled, usage is then reduced to as needed. In animals unable to tolerate therapy, concentration may be reduced to 0.025–0.01% in an attempt to balance efficacy with adverse effects.

Avoid contact with eyes, nostrils, inner ears, or mouth. Clients should wear gloves when applying the product.

Adverse effects can include hypersensitivity reactions or local irritation.

Veterinary-Labeled Tretinoin Topical Products: None

Antiparasitic Agents, Topical

For agents such as **epinomectin**, **ivermectin**, **levamisole**, **moxidectin** and **selamectin** that may be administered topically, but absorbed through the skin to treat internal parasites as well as external parasites, refer to the monographs in the main (systemic drugs) section of the Handbook. Also see monographs in the main section for those products administered orally for their external parasitic actions, including **lufenuron**, **nitenpyram**, and **milbemycin**. Because **spinosad** was released after the main monographs went to press, it is included here for this edition only.

AMITRAZ

(a-mi-traz) Mitaban®, Taktic® EC, Preventic®, ProMeris® for Dogs

Indications/Actions

In dogs, amitraz solution is used topically primarily in the treatment of generalized demodicosis. A topical spot-on solution (*ProMeris® for Dogs*) and a collar (*Preventic®*) are available for treatment and prevention of flea and tick infestation. It is also used as a general insecticidal/miticidal agent in several other species (see label information). The pharmacologic action of amitraz is not well understood, but it is a monoamine oxidase (MAO) inhibitor (in mites) and may have effects on the CNS of susceptible organisms. It apparently also possesses alpha-2 adrenergic activity and inhibits prostaglandin synthesis. Amitraz can cause a significant increase in plasma glucose levels, presumably by inhibiting insulin release via its alpha2-adrenergic activity. Yohimbine (alpha2 blocker) or atipamezole can antagonize this effect.

Administration/Suggested Dosages

Amitraz liquid concentrates are flammable until diluted with water. Do not stress animals for at least 24 hours after application of *Mitaban®*. When mixing with water, protect exposed skin with rubber gloves, etc. Wash hands and arms well after application to animal. Dispose of unused diluted solution by flushing down the drain. Rinse *Mitaban®* container with water and dispose; do not re-use. Do not re-use collar or container; wrap in newspaper and throw in trash. Avoid inhalation of vapors. Animals treated may exhibit signs of sedation; if animal is un-arousable or sedation persists for longer than 72 hours, contact your veterinarian.

DOGS:

For treatment of generalized demodicosis:

- Long and medium haired dogs should be clipped closely and given a shampoo with mild soap and water prior to first treatment. Topically treat at a concentration of 250 ppm (one 10.6 mL bottle of *Mitaban®* in 2 gallons of warm water, by applying to entire animal and allowing to air dry. DO NOT rinse or towel dry. Use a freshly prepared dilution for additional dogs or additional treatments. Repeat every 14 days for 3–6 treatments (continue until six treatments done or two successive skin scrapings demonstrate no live mites). Chronic cases may require additional courses of therapy. (Package Insert; *Mitaban®*—Upjohn)
- For dogs who are only controlled with chronic therapy (as above) and whose owners accept the risk of using the drug in an “unlicensed” manner in an attempt for cure: Owners should be made aware of the risks of therapy and accept them. First, try the 250 ppm solution (as above once weekly for 4 weeks. If positive response is seen, continue until all mites eradicated (using skin scrapings) and then for an additional 30 days. If weekly 250 ppm application fails, a 500 ppm solution may be tried (1 bottle in 1 gallon of water) weekly as above. In dogs failing 500 ppm, 1000 ppm may also be attempted, but likelihood of toxicity increases and the author has no experience using it. If these methods fail, the dog is unlikely to be cured using amitraz. (Miller 1992)
- For dogs not responding to conventional (labeled) therapy: Prepare a 0.125% solution by diluting 1 mL of the 12.5% commercially available large animal product (*Taktic®*) in 100 mL of water. Clip and bathe with appropriate shampoos once weekly if required. Using a sponge rub the diluted solution (0.125%) daily onto one-half of the dog's body and alternate sides on a daily basis. Air dry. During the first week of therapy, keep dog hospitalized and observe for adverse effects. Continue therapy for 2 weeks after multiple skin scrapings are negative for mites. Dogs also receive otic therapy with a diluted solution of amitraz (1 mL of Tactic in 8.5 mL of mineral oil) every 3–7 days unless irritation develops and one researcher also treats dogs with pododermatitis with daily foot soaks of the 0.125% solution. Preliminary results look promising and reported adverse effects in dogs are low in frequency and mild. Owners accepting this un-approved therapy, must be carefully screened and trained to carefully handle the amitraz solutions. (Mundell 1994)

For scabies in older puppies and adult dogs:

- Dilute and treat per label recommendation (see “a” above for demodicosis) for 3 treatments (Moriello 1992)
- Dilute and treat per label directions (*Mitaban®*; 250 ppm); apply once to three times at 2–week intervals for a 4–6 week course of treatment (Foil 2003)

CATS: (see warning to not use in cats below)

For demodicosis:

- Dilute amitraz to 125 ppm and apply every 7–14 days (White 2000)

RABBITS/RODENTS/POCKET PETS:

- Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 1.4 mL per liter topically every 2 weeks (q14 days) for 3–6 treatments. Caution: Not recommended in young animals. (Adamcak and Otten 2000)
- Rabbits: Not recommended.

GOATS:

For demodectic mange:

- a) 10.6 mL of amitraz solution (19.9%—*Mitaban*®) in 2 gallons of water. Use as a whole body dip; repeat every 14 days for 2–3 treatments (Rosser 1993)

Precautions/Adverse Effects/Drug Interactions

Safety has not been demonstrated in dogs less than 4 months of age. The manufacturer of *Mitaban*® does not recommend use in these animals. Toy breeds may be more susceptible to CNS effects (transient sedation); lower dose rates (1/2 of recommended) have been recommended in these breeds. Because of the drug's effects on plasma glucose, use with caution in brittle diabetic patients. Reproductive safety has not been established. Use only when benefits outweigh potential risks of therapy.

The most commonly reported adverse effect after amitraz topical administration is transient sedation that may persist for up to 72 hours (24 hours is usual). If treating around eyes, use an ophthalmic protectant (e.g., petrolatum ophthalmic ointment) before treating. Do not use if dog has deep pyodermas with drainage tracts; postpone application until lesions improve after treating with antibiotic and shampoo therapy. Other adverse effects include: ataxia, bradycardia, vomiting, diarrhea, hypothermia and a transient hyperglycemia. Rarely, seizures have been reported. Topical effects can include edema, erythema and pruritus. Adverse effects are more likely to be seen in debilitated, geriatric, or very small breed dogs.

Amitraz can be toxic to cats and rabbits and it is probably best to avoid its use in these species, although amitraz has been used safely in cats in diluted form for the treatment of demodicosis in cats.

Amitraz may be toxic if swallowed (by either animals or humans). Beagles receiving 4 mg/kg PO daily for 90 days, demonstrated transient ataxia, CNS depression, hyperglycemia, decreased pulse rates and lowered body temperature. No animals died.

Amitraz toxicity can be significant if amitraz-containing insecticide collars are ingested. Treatment should consist of emesis, retrieval of the collar using endoscopy if possible and administration of activated charcoal and a cathartic to remove any remaining collar fragments. Because of the risk of an increased chance of gastric dilatation, gastrotomy may not be a viable option. Yohimbine at a dose of 0.11–0.2 mg/kg IV (start with low dosage) may be of benefit for overdose effects. Because yohimbine has a short half-life it may need to be repeated, particularly if the animal has ingested an amitraz-containing collar that has not been retrieved from the GI tract. Atipamezole has also been used to treat amitraz toxicity; refer to that monograph for more information. Contact a poison center for more information, if necessary.

Because of their immunosuppressive effects, **corticosteroids** and **other immunosuppressant drugs** (e.g., azathioprine, cyclophosphamide, etc) should not be used in animals with demodicosis.

Amitraz may interact with other MAO inhibitors (including **selegiline**) or tricyclic antidepressants (**amitriptyline**, **clomipramine**). Concomitant use is not recommended.

Clients should wear gloves when applying and wash off any product that contacts their skin.

Veterinary-Labeled Amitraz Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Mitaban ® (Pfizer) Note: This product's availability has been undependable in past years; may not be available	Solution for Dilution: 19.9%	Rx (Vet)	10.6 mL btls. FDA labeled and approved for use on dogs. Note: Liquid is flammable until diluted.
Tactic ®EC (Intervet)	Solution (emulsifiable concentrate) for Dilution: 12.5%	OTC-EPA (Vet)	760 mL cans. EPA labeled for use on swine, dairy or beef cattle. Label states not to use on dogs or horses.

Preventic ® (Virbac)	Collar: 9% amitraz; 25 inch	OTC-EPA (Vet)	25 in. adjustable (cut off excess). EPA labeled for dogs 12 weeks and older only. Effective for 3 months.

Human-Labeled Amitraz Topical Products: None

CROTAMITON

(kroe-ta-mye-ton) Eurax®

Indications/Actions

Crotamiton is a topical miticide/scabicide and has been used primarily for adjunctive treatment (with ivermectin) for treating mite infections (e.g., *Knemidoptes*) in birds. Crotamiton has both miticidal and antipruritic actions, but the mechanism for each is not known.

Suggested Dosages/Precautions/Adverse Effects

Once to twice daily applications are usually recommended. Do not apply around eyes or mouth. Little is known of the compound's safety profile; irritation or hypersensitivity reactions are possible.

FIPRONIL ± (S)-METHOPRENE

(TOPICAL)

(*fip-roe-nil*; *meth-oh-preen*) Frontline®, Frontline® Plus

Indications/Actions

In the USA, Fipronil is indicated for the treatment of fleas, ticks and chewing lice infestations in dogs and cats, and as an aid in control of sarcoptic mites in dogs. Fipronil is a phenylpyrazole antiparasitic agent, that in invertebrates interferes with the passage of chloride ions in GABA regulated chloride channels, thereby disrupting CNS activity causing death of the flea or tick. The manufacturer states that fipronil collects in the oils of the skin and hair follicles and continues to be released over a period a time resulting in long residual activity. Topically applied, the drug apparently spreads over the body in approximately 24 hours via translocation.

When fipronil is combined with the insect growth regulator (S)-methoprene (*Frontline® Plus*), additionally flea eggs and flea larvae are killed. (S)-methoprene mimics flea juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced.

Suggested Dosages/Precautions/Adverse Effects

Monthly treatments are usually recommended when used for fleas, ticks or chewing lice. See product labels for specific directions on administration and recommendations on bathing/swimming, etc after administration. For the control of sarcoptic mange mites, multiple monthly treatments may be needed.

Do not use on puppies or kittens less than 8 weeks of age. While temporary irritation may occur at the site of administration, animals that have demonstrated sensitivity reactions to fipronil or any of the ingredients in the product, should probably not be retreated.

The manufacturer recommends to consult a veterinarian before using on debilitated, aged, or medicated patients.

This product is reportedly to be contraindicated in rabbits as deaths have occurred with the spray. Do not apply or spray in eyes.

Do not contaminate food or water and dispose of container properly. Avoid human contact with skin, eyes or clothing and wear gloves when applying/spraying. If using spray, do so in a well ventilated area. Avoid contact with animal until dry. Wash well with soap and water if contact occurs.

Product is labeled as remaining effective after bathing (but do not shampoo within 48 hours of application), water immersion, or exposure to sunlight. Spotted areas may appear wet or oily for up to 24 hours after application.

Rarely, hypersensitivity has been reported. Temporary irritation may occur at the site of administration.

Veterinary-Labeled Fipronil w/ and w/o (s)-Methoprene Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Frontline® Spray Treatment (Merial)	Spray: 0.29% fipronil	OTC-EPA (Vet)	8.5, 17 oz. Labeled for use on dogs, cats, puppies, kittens 8 weeks of age or older.

Human-Labeled Fipronil Topical Products: None

IMIDACLOPRID

IMIDACLOPRID WITH PERMETHRIN, TOPICAL

IMIDACLOPRID WITH MOXIDECTIN, TOPICAL

(eye-mi-da-*kloe*-prid, per-*meth*-rin, *mox*-ih-dek-tin) Advantage®, K9 Advantix®, Advantage®, Advocate®

Indications/Actions

Imidacloprid topical solution is indicated for the treatment of adult and larval stage fleas in dogs and cats. The combination product with permethrin (*K9 Advantix*®) is indicated for adulticide/larvicide for fleas, to repel and kill ticks, and mosquitoes in dogs only. The canine combination product with moxidectin is indicated for the prevention of heartworm disease, adult fleas, adult and immature hookworms, adult roundworms, and adult whipworms; the feline combination product is indicated for the prevention of heartworm disease, adult fleas, ear mites, adult and immature hookworms, and adult roundworms.

Imidacloprid's mechanism of action as an insecticide is to act on nicotinic acetylcholine receptors on the postsynaptic membrane causing CNS impairment and death. Certain insect species are more sensitive to these agents than are mammalian receptors. This is a different mechanism of action than other insecticidal agents (organophosphates, pyrethrins, carbamates, insect growth regulators (IGR's) and insect development inhibitors (IDIs)). The manufacturer states that imidacloprid is non-teratogenic, non-hypersensitizing, non-mutagenic, non-allergenic, non-carcinogenic, and non-photosensitizing. The manufacturer states that when applied topically the compound is not absorbed into the bloodstream or internal organs. The combination product for dogs also contains permethrin, a pyrethroid (synthetic pyrethrin) that will kill and repel ticks and mosquitoes. Permethrin's insecticidal activity is as a neurotoxin in susceptible species by slowing sodium ions through sodium channels in neuron membranes.

Suggested Dosages/Precautions/Adverse Effects/Overdoses

Refer to the package information for specific instructions on application of imidacloprid products. They are generally administered once monthly. While swimming, bathing, and rain do not apparently significantly affect the duration of action, repeated shampooing may require additional treatment(s) before the monthly dosing interval is completed. Do not reapply more often than once weekly for these animals. The feline product has also been suggested as useful in rabbits: Use feline dose (*Advantage*®); place in 2–3 areas along dorsum (Ivey and Morrissy 2000).

The manufacturer lists the following contraindications for imidacloprid (alone): do not use in puppies as younger than 7 weeks old or kittens younger than 8 weeks old. The manufacturer recommends consulting a veterinarian before using on debilitated, aged, pregnant, or nursing animals or those on medication.

The combination product with permethrin (*K9 Advantix*®) **must not be used on cats**. Use with caution in households with both dogs and cats, particularly if cats are in close contact or will groom dogs in the household.

When used as directed, adverse effects are unlikely. Because the drug is bitter tasting, oral contact may cause excessive salivation. Do not get product in eyes. If eye contact occurs (human or animal), flush well with ophthalmic irrigation solution or water. While gloving is not mandated, it should be encouraged as contact with skin should be avoided. Wash hands with soap and water after handling. Keep out of reach of children and do not contaminate feed or food. Dispose of product carefully (in the trash); the permethrin-containing product is extremely toxic to fish.

There were 188 exposures to imidacloprid reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 95 were dogs with 11 showing clinical signs, 92 cases were cats in which 20 showed clinical signs, and the remaining case was a bird that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, diarrhea and hypersalivation. Common findings in cats recorded in decreasing frequency included hypersalivation, vomiting and anorexia.

Human-Labeled Imidacloprid Topical Products: None

METAFLUMIZONE

(met-ah-floo-mih-zone) ProMeris®

Indications/Actions

Metaflumizone is a new insecticide used for the treatment and control of fleas on dogs and cats. It blocks the influx of sodium required to propagate a nerve impulse along the axon and dendrite of the neuron causing a reduction in feeding, loss of coordination, paralysis and death of the flea.

Suggested Dosages/Precautions/Adverse Effects

New product at the time of writing; refer to the package information for specific instructions on application, precautions and adverse effects.

Veterinary-Labeled Imidacloprid Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments

ProMeris® for Dogs (Fort Dodge)	Spot-On Solution: amitraz 150 mg/mL; metaflumizone 150 mg/mL	OTC-EPA (Vet)	Approved, but not released in USA at time of writing (August 2007). See label for more details.

Human-Labeled Metaflumizone Topical Products: None

(S)-METHOPRENE COMBINATIONS

(TOPICAL)

(meth-oh-preen)

Also see the Fipronil ± (S)-Methoprene listing

Indications/Actions

Methoprene is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability prevent maturation of eggs or larva. (s)-methoprene mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (e.g., permethrin, fipronil, phenothrin) all stages of the parasite are killed and re-infestation is less likely.

Suggested Dosages/Precautions/Adverse Effects

For specific dosage recommendations, refer to the actual product's label.

Methoprene may be found in products also containing **permethrin or phenothrin which can be toxic to cats**, particularly small kittens. **Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats.** Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes.

Methoprene (use alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur. As methoprene is broken down by UV light, protect unused product from light.

Veterinary-Labeled (S)-Methoprene Topical Products (Not necessarily inclusive)

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Hartz Advanced Care 4 in 1 Flea & Tick Drops Plus+ for Dogs and Puppies® (Hartz Mountain)	Topical Solution: (s)-methoprene: 2.3% phenothrin: 85.7%	OTC-EPA (Vet)	Note: Phenothrin is a pyrethroid similar to permethrin; refer to the permethrin monograph for more information. Frontline® Plus for Dogs & Puppies (Merial)	Solution: 9.7% fipronil, (s)-methoprene 8.8%	OTC-EPA (Vet)	Single dose applicators in 3's and 6's; Labeled for dogs or puppies 8 weeks of age or older. For dogs weighing 11–22 lb.: 0.67 mL For dogs weighing 23–44 lb.: 1.34 mL For dogs weighing 45–88 lb.: 2.68 mL For dogs weighing 89–132 lb.: 4.02 mL
Vet-Kem Breakaway Plus Flea & Tick Collar for Cats® (Wellmark); Sergeant's Double Duty Flea & Tick Collar for Cats® (Sergeant's)	Collar: (s)-Methoprene: 2.1% Propoxur: 10 %	OTC-EPA (Vet)	Do not use on kittens less than 12 weeks old. Propoxur is a carbamate insecticide.
Sergeant's Double Duty Flea & Tick Collar for Dogs & Puppies® (Sergeant's)	Collar: (s)-Methoprene: 2.1% Propoxur: 10 %	OTC-EPA (Vet)	Do not use on puppies less than 12 weeks old. Propoxur is a carbamate insecticide.
Hartz Advanced Care 3 in 1 Control Collar for Puppies® (Hartz Mountain)	Collar: (s)-Methoprene: 2.1% Tetrachlorvinphos: 14.55 %	OTC-EPA (Vet)	Tetrachlorvinphos is an organophosphate insecticide. Not for use on puppies under 6 weeks old. Fits up to 15 inch necks.
Hartz Advanced Care 3 in 1 Control Collar for Dogs® (Hartz Mountain)	Collar: (s)-Methoprene: 1.02% Tetrachlorvinphos: 14.55 %	OTC-EPA (Vet)	Tetrachlorvinphos is an organophosphate insecticide. Not for use on puppies under 6 weeks old. Fits up to 23 inch necks.

Human-Labeled (S)-Methoprene Topical Products: None**PYRIPROXYFEN & PYRIPROXYFEN COMBINATIONS****(TOPICAL)**

(pye-ri-proks-i-fen) Nylar®

Indications/Actions

Like methoprene, pyriproxyfen is an insect growth regulator and is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability to prevent maturation of eggs or larva. Pyriproxyfen mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (e.g., permethrin, fipronil) all stages of the parasite are killed and re-infestation is less likely. It is more resistant to UV light than is methoprene.

Suggested Dosages/Precautions/Adverse Effects

For specific dosage recommendations, refer to the actual product's label.

Pyriproxyfen may be found in products also containing **permethrin which can be toxic to cats**, particularly small kittens. **Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats.**

Pyriproxyfen (used alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur.

Clients should wear gloves when applying products containing permethrin or other insecticides and wash off any product that contacts their skin.

Veterinary-Labeled Pyriproxyfen Topical Products

(Not necessarily inclusive, there are premise sprays and other topical products containing pyriproxyfen)

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Scratchex® Dog Stripe-On Flea & Tick Control (Farnam); Bio Spot® Flea & Tick Control for Dogs (Farnam)	Topical Solution: Permethrin 45% Pyriproxyfen 5%	OTC-EPA (Vet)	3 per package. For dogs only, older than 12 weeks old. Individual packaging for dog's weighing: <15 lb = 1 mL 15–33 lb = 1.5 mL 33–66 lb. = 3 mL >66 lb. = 4.5 mL
Bio Spot® Stripe-On Flea & Tick Control for Cats; Scratchex® Cat Stripe-On Flea Control (Farnam)	Topical Solution: Pyriproxyfen 5.3%	OTC-EPA (Vet)	2 – 15 mL applicators. For cats over 12 weeks old.
Virbac Long Acting Knockout® (Virbac)	Topical Spray: Permethrin 2 % Pyriproxyfen 0.05%	OTC-EPA (Vet)	16 oz. For use on dogs only.
Adams® Flea & Tick Mist with IGR (Adams)	Topical Spray: Pyrethrins 0.18% Pyriproxyfen 0.125%	OTC-EPA (Vet)	N-octyl bicycloheptane dicarboxamide 1% (insecticide synergist). 16, 32 oz. For dogs and cats.
Adams® Flea & Tick Mist with Sykillstop (Adams)	Topical Spray: Pyrethrins 0.15% Pyriproxyfen 0.15% Piperonyl butoxide 1.5%	OTC-EPA (Vet)	N-octyl bicycloheptane dicarboxamide 0.5% (insecticide synergist). 16, 32 oz. For dogs and cats, puppies, kittens.
Adams® Flea & Tick Shampoo with Sykillstop (Adams)	Shampoo: Pyrethrins 0.075% Pyriproxyfen 0.75% Piperonyl butoxide 1.5%	OTC-EPA (Vet)	16, 32 oz. For dogs and cats, puppies, kittens.
Bio Spot® Shampoo (Farnam)	Shampoo: Pyrethrins 0.1% Pyriproxyfen 0.01% Piperonyl butoxide 0.5%	OTC-EPA (Vet)	12 oz. For dogs.
Virbac Knockout® IGR Flea Collar for Cats & Kittens (Virbac)	Collar: Pyriproxyfen 0.5%	OTC-EPA (Vet)	May be used for up to 13 months.
Virbac Knockout® IGR Flea Collar for Dogs & Puppies (Virbac)	Collar: Pyriproxyfen 0.5%	OTC-EPA (Vet)	Do not use on puppies less than 3 months old. May be used for up to 13 months.

Human-Labeled Pyriproxyfen Topical Products: None

PERMETHRIN

(per-meth-rin)

Also see the Imidacloprid ± Permethrin listing

Indications/Actions

Permethrin is synthetic pyrethroid that acts as an adulticide insecticide/miticide. It has knockdown activity against fleas, lice, ticks, and certain mites (e.g., Cheyletiella, *Sarcoptes scabiei*) and also has repellent activity. In small animal medicine, it is used primarily for fleas and ticks on dogs. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use for flies, lice, mites, mosquitoes, ticks and keds.

Permethrin acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

Suggested Dosages/Precautions/Adverse Effects

For specific dosage recommendations, refer to the actual product's label.

Permethrin (and other synthetic pyrethroids) can be toxic to cats, particularly small kittens. **Only use products containing pyrethroids labeled for use on cats on this species.** Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

Clients should wear gloves when applying and wash off any product that contacts their skin.

Veterinary-Labeled Permethrin Products

(Not inclusive; many shampoos, pour-ons, sprays, dusts are available)

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
ProTICall® Insecticide for Dogs (Schering-Plough)	Spot-On Liquid: Permethrin 65%	OTC-EPA (Vet)	6 X 1 mL applicators. Dosing amounts vary with dog weight; refer to directions. Labeled for use on puppies as young as 4 weeks old.
K9 Advantix® (Bayer)	Topical Solution: Imidacloprid 8.8%, Permethrin 44%	OTC-EPA (Vet); Manufacturer restricts sales to licensed veterinarians	Flea adulticide/larvicide, tick and mosquito repellent and treatment. For use on dogs and puppies 7 weeks of age and older. In cards of 4 or 6 tubes: Under 10 lb. = 0.4 mL (green) 11–20 lb. = 1 mL (teal) 21–55 lb. = 2.5 mL (red) Over 55 lb. = 4 mL (blue)
Bansect® Squeeze-On Flea & Tick Control for Dogs® (Sergeant's)	Topical Solution: Permethrin 45%	OTC-EPA (Vet)	3 per package. For dogs only, older than 6 months old. Individual packaging for dog's weighing: < 33 lb. = 1.5 mL >33 lb. = 3 mL
Scratchex® Dog Stripe-On Flea & Tick Control (Farnam); Biospot® Flea & Tick Control for Dogs (Farnam)	Topical Solution: Permethrin 45% Pyriproxyfen 5%	OTC-EPA (Vet)	3 per package. For dogs only, older than 12 weeks old. Individual packaging for dog's weighing: <15 lb = 1 mL 15–33 lb = 1.5 mL 33–66 lb. = 3 mL >66 lb. = 4.5 mL
Vectra 3D® (Summit)	Topical Solution: Permethrin 36.08%, Pyriproxyfen 0.44%, dinotefuran, 4.95%	OTC-EPA (Vet)	In 4 different package sizes for dogs weighing >2.5. lb. For use on dogs over 7 weeks old only.
Virbac Long Acting Knockout® (Virbac)	Spray: Permethrin 2 % Pyriproxyfen 0.05%	OTC-EPA (Vet)	16 oz. For use on dogs only.

Human-Labeled Permethrin Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Generic (various), Elimate® (Allergan), Acticin® (Bertek)	Cream: Permethrin 5%	Rx (Human)	60 g. Used for treating scabies in humans.
Generic (various)	Lotion/Cream Rinse: Permethrin 1%	OTC (Human)	60 mL. Used for treating head lice in humans.

PYRETHRINS AND PYRETHRIN COMBINATIONS**(TOPICAL)****(pye-ree-thrins)**

For otic use, refer to the Otic appendix

Indications/Actions

Pyrethrins are naturally-derived insecticides that acts as an adulticide insecticides/miticides. It has knockdown activity against fleas, lice, ticks, and Cheyletiella. In small animal medicine, it is used primarily for fleas and ticks on dogs and cats. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use.

Pyrethrins act by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death. Pyrethrins are often found in combination with the insect growth regulators, methoprene or pyriproxyfen and with the synergist piperonyl butoxide. Piperonyl butoxide inhibits insect metabolic enzymes (P450 system) allowing a lower dose of primary insecticide to be used.

Suggested Dosages/Precautions/Adverse Effects

For specific dosage recommendations, refer to the actual product's label.

Pyrethrins are among the safest insecticidal products available, but cats should not be allowed to groom wet product after using dips or sprays. Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes. Avoid hypothermia when using liquid products (sprays, dips, etc), particularly in small animals and when ambient temperatures are low.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

Clients should wear gloves when applying and wash off any product that contacts their skin.

Veterinary-Labeled Pyrethrin Products

(Not an inclusive list, but representative of the types of products available; many shampoos, pour-ons, sprays, dusts, ointments are available)

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Ecto-Foam® (Virbac)	Topical Foam: Pyrethrins: 0.15% Piperonyl Butoxide 0.7%	OTC-EPA (Vet)	N-octyl bicycloheptane dicarboxamide 0.34% (insecticide synergist). 9 oz. Contains both microencapsulated and unencapsulated pyrethrins. For dogs and cats older than 12 weeks.
Adams Flea & Tick Dust II® (VPL)	Dust: Pyrethrins 0.1% Carbaryl 12.5% Piperonyl butoxide 1%	OTC-EPA (Vet)	Silica gel 10%. 3 oz. Odorless. Labeled for dogs, cats, puppies, kittens over 12 weeks old.
Adams Flea & Tick Mist with IGR® (Adams)	Topical Spray: Pyrethrins 0.18% Pyriproxyfen 0.125%	OTC-EPA (Vet)	N-octyl bicycloheptane dicarboxamide 1% (insecticide synergist). 16, 32 oz. For dogs and cats.
Adams Flea & Tick Mist with Sykillstop® (Adams)	Topical Spray: Pyrethrins 0.15% Pyriproxyfen 0.15% Piperonyl butoxide 1.5%	OTC-EPA (Vet)	N-octyl bicycloheptane dicarboxamide 0.5% (insecticide synergist). 16, 32 oz. For dogs and cats, puppies, kittens.
Vet-Kem Ovitrol Plus Flea, Tick & Bot Spray® (Wellmark)	Topical Spray: (s)-Methoprene: 0.27% Pyrethrins: 0.2% Piperonyl Butoxide 0.37%	OTC-EPA (Vet)	N-octyl bicycloheptene dicarboximide: 0.62%. 16 oz., 1 gal. labeled for use on dogs, cats, puppies, kittens, horses, and ponies. Not for puppies or kittens less than 12 weeks old.
Adams Flea & Tick Shampoo with Sykillstop® (Adams)	Shampoo: Pyrethrins 0.075% Pyriproxyfen 0.75% Piperonyl butoxide 1.5%	OTC-EPA (Vet)	16, 32 oz. For dogs and cats, puppies, kittens.
Bio Spot Shampoo® (Farnam)	Shampoo: Pyrethrins 0.1% Pyriproxyfen 0.01% Piperonyl butoxide 0.5%	OTC-EPA (Vet)	12 oz. For dogs.
Vet-Kem Ovitrol Plus Flea & Tick Shampoo® (Wellmark)	Shampoo: (s)-Methoprene: 1.1% Pyrethrins: 0.15% Piperonyl butoxide:1.05%	OTC-EPA (Vet)	12 oz. Not for puppies or kittens less than 12 weeks old.
Ectokyl 3X Flea & Tick Shampoo® (DVM)	Shampoo: Pyrethrins: 0.15% Piperonyl butoxide:1% N-octyl bicycloheptene dicarboxamide 0.5% Di-n-propyl isocinchomerate 0.5%	OTC-EPA (Vet)	Oatmeal, aloe. 8 oz, 1 gal. Not for puppies or kittens less than 12 weeks old.
Pyrethrin Plus Shampoo® (Vedco)	Shampoo: Pyrethrins: 0.15% Piperonyl butoxide:1.5% N-octyl bicycloheptene dicarboxamide 0.5%	OTC-EPA (Vet)	6, 12 oz, 1 gal.
Pyrethrins Dip and Spray® (Davis)	Dip & Spray: Pyrethrins 3% Piperonyl butoxide 30%	OTC-EPA (Vet)	Petroleum distillate 12%. 16 oz, 1 gal. Keep away from open flame. Not for puppies or kittens less than 4 weeks old. Must be diluted before use.
Virbac Pyrethrin Dip® (Virbac)	Dip: Pyrethrins: 1% Piperonyl butoxide: 4% N-octyl bicycloheptene dicarboxamide 6% Di-n-propyl isocinchomerate 4%	OTC-EPA (Vet)	4 oz, 1 gal. Not for puppies or kittens less than 6 weeks old. Must be diluted before use.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Adams Pyrethrin Dip® (Farnam)	Dip: Pyrethrins: 0.97% Piperonyl butoxide: 3.74% N-octyl bicycloheptene dicarboxamide 5.7% Di-n-propyl isocinchomerate 1.94%	OTC-EPA (Vet)	4 oz. Not for puppies or kittens less than 12 weeks old. Must be diluted before use.

Human-Labeled Pyrethrin Topical Products: None

SPINOSAD

(*spin-oh-sad*) Comfortis®

Note: This product was released after the systemic monographs went to press and although it is not a topical drug, is inserted here for this edition only.

Indications/Actions

For the prevention and treatment of fleas for one month on dogs 14 weeks of age and older.

Spinosad is a group 5 nicotinic acetylcholine receptor agonist, that causes involuntary muscle contractions and tremors secondary to motor neuron activation. Prolonged exposure causes paralysis and flea death. Flea death begins within 30 minutes of dosing and in 4 hours is complete. Spinosad does not interact with bindings sites of other insecticidal agents (GABA-ergic or nicotinic).

Suggested Dosages/Precautions/Adverse Effects

One tablet a minimum dosage of 30 mg/kg once monthly; give with food

No labeled contraindications; not approved for use in cats. Higher than labeled dosages may decrease seizure threshold in epileptic dogs.

May cause vomiting, decreased appetite, lethargy, or diarrhea.

Veterinary-Labeled Spinosad Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s); Comments
Comfortis® (Lilly)	Chewable Tablets: Spinosad 140, 270, 560, 810, 1620 mg	Rx (Vet)	Store at room temperature

Human-Labeled Spinosad Products: None

OTIC Preparations

While not a complete list, the following examples are representative of the types of topical otic preparations available to the veterinarian. For more information on treating diseases of the ear, including the use of systemic therapy, refer to the chapter on ear diseases by Radlinsky, MG and Mason, DE in the Textbook of Veterinary Internal Medicine, 6th Ed. by Ettinger and Feldman. Elsevier Saunders, Publisher. Additional information and suggested doses were obtained from a variety of sources including: the above mentioned reference by Drs. Radlinsky and Mason; Dr Sheila Torres (personal communication); proceedings authored by Dr Paul B. Bloom (Western Veterinary Conference 2006), and Dr. Marcia Schwassmann (Western Veterinary Conference 2005). Refer to the product label before using any product.

Ear Cleaners/Flushes/Antiseptic/Disinfectant Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Ace-Otic Cleanser ® (Vetus)	Acetic acid, lactic acid, salicylic acid		
Adams Pan-Otic ® (Pfizer)	DSS		
ADL Ear Cleanser ® (ADL)	Cocamidopropyl betaine, isosteramido-propyl morpholine lactate		Good for waxy discharges
ADL Ear Flushing Drying Lotion ® (ADL)			Good for waxy discharges
Alocetic ® (DVM)	Acetic acid, aloe		
Alocetic Ear Rinse ® (DVM)	Acetic Acid, Nonoxynol 12	Fill ear canal, massage and remove	May be irritating if using in the higher concentrations
Betadine ® Solution 10% (P-F); Generic	Povidone Iodine 10%	Dilute 1:10 – 1:50 in water and use as an ear flush prn	Must be diluted before use
Cerulytic ® (Virbac)	Benzyl alcohol, butylated hydroxytoluene	Few drops in each ear canal, massage and clean	To reduce and prevent earwax accumulation
Cerumene ® (Vetoquinol)	Squalane 25%	Fill ear canal, massage for several minutes and remove; flush and dry	To reduce and prevent earwax accumulation; Good for waxy discharges
Chlorhexiderm ® Flush (DVM)	Chlorhexidine gluconate	As an ear flush, Fill ear, massage and clean ear using absorbent material.	May be effective for treating Pseudomonas
ClearX Ear Cleaning Solution ® (DVM)	DSS (docusate) 6.5%; urea (carbamide) peroxide 6%	1 – 2 ml per ear prn	May be irritating if animal is awake. Suggest using in clinic only to allow suction.
Clearx Ear Drying Solution ® (DVM)	Acetic acid, colloidal sulfur, hydrocortisone		
Corium-20 ® (Virbac)	SDA-40B 23%, glycerol		
Ear Cleansing Solution ® (Vet Solutions)	Propylene glycol, aloe vera gel, lactic acid, DSS, salicylic acid, benzoic acid		
Earoxyde Ear Cleanser ® (Tomlyn)	6.5% carbamide peroxide		
Epi-Otic ® (Virbac)	Lactic acid & salicylic acid in <i>Spherulites</i> ®, encapsulated chitosanide, DSS, propylene glycol	Fill ear canal q24-48h prn	Has ceruminolytic/ & drying activity. Also has mild antibacterial and antifungal activity
Epi-Otic Advanced ® (Virbac)	Salicylic acid 0.2%		
Euclens Otic Cleanser ® (Vetus)	Propylene glycol, malic acid, benzoic acid		
Fresh-Ear ® (Q.A. Laboratories)	Lidocaine hydrochloride, boric acid, acetic acid		
Gent-L-Clens ® (Schering-Plough)	Lactic acid, salicylic acid		
Hexadene Flush ® (Virbac)	0.25% chlorhexidine gluconate, triclosan		
Klearwax ® (Dermapet)	DSS 5%, urea peroxide 5%		
MalAcetic Otic ® (Dermapet)	Acetic acid 2%, boric acid 2%	Flood ear canal once to twice a day for 14 days, then as needed	Also available in apple fragrance
Micro Pearls Advantage Advanced pHormula Ear Cleanser ® (Vetoquinol)	Alkyl benzoate, citric acid, sodium citrate, glycerin, glycerol distearate, allantoin	Apply liberally into ear canal and massage	Cleans and reduces pH to less than 5 for up to 18 hours

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Nolvacleanse ® (Fort Dodge)	Propylene glycol, surfactants	Flood ear canal once to twice a day for 14 days, then as needed	
Oti-Calm ® (DVM)	Benzoic, malic, salicylic acids; oil of eucalyptus	Fill ear, massage and clean ear using absorbent material. Use once to twice a week.	Has ceruminolytic, mild antibacterial and antifungal actions
Otic Clear ® (Butler)	Lidocaine hydrochloride, boric acid, acetic acid		
Oti-Clens ® (Pfizer)	Propylene glycol, malic, benzoic and salicylic acids	Fill ear; use q24-48h or as necessary	Has ceruminolytic, mild antibacterial and antifungal actions; also drying agent
Otic Domeboro ® (Miles) Note: human product	Acetic acid 2% aluminum acetate	For ear drying (astringent): fill ear q12-48h	For swimmer's otitis
OtiFoam ® (DVM)	Cocamidopropyl betaine, mackalene 426		Good for waxy discharges
OtiRinse ® (DVM)	Nonoxynol-12, salicylic acid, benzoic acid, DSS		Good for waxy discharges
Otocetic Solution ® (Vedco)	2% boric acid, 2% acetic acids		
Sterile Normal Saline	Sodium Chloride 0.9%	Use as an ear flush prn	Cleaner, drying agent. Gentle; can be used if tympanum absent
T8 Ear Rinse ® (DVM)	Tromethamine; tetrasodium edetate		
Triz-EDTA® Aqueous Flush (Dermapet)	Tromethamine; edetate disodium dihydrate, chlorhexadine digluconate 0.15%		
Triz-EDTA® Plus (Dermapet)	Tromethamine; edetate disodium dihydrate		
Vinegar:Water 50:50			Gentle; can be used if tympanum absent
Wax-O-Sol ® (Life Science)	Hexamethyltetracosane 25%		
Xenodyne ® (VPL)	Polyhydroxidine iodine 0.5%	Dilute 1:1 to 1:5 in water. Use prn as an ear flush; once weekly for treating ear mites; q12h for treating refractory Pseudomonas otitis	

Corticosteroid/Antiinflammatory Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Buro-O-Cort 2:1 ® (Q.A. Laboratories)	Burow's solution, hydrocortisone		
Bur-Otic HC ® (Virbac)	1% hydrocortisone, burow's solution, acetic acid, benzalkonium chloride		
Clearx Drying Solution ® (DVM)	Acetic acid, colloidal sulfur, hydrocortisone		
Cor/Astrin Solution ® (Vedco)	Burow's solution, 1% hydrocortisone		
MalAcetic HC ® (Dermapet)	Hydrocortisone 1%, boric acid, acetic acid		For ear cleaning especially if ears inflamed or irritated
Synotic Otic Solution ® (Fort Dodge)	Fluocinolone 0.01%; DMSO 60%	2-12 drops (depending on size of ear) q12h initially, then q48-72h maintenance	For moderate to severe allergic otitis or hyperplastic/proliferative otitis

Antimicrobial (Antibacterial) Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Baytril Otic [®] (Bayer)	Enrofloxacin 0.5%, Silver sulfadiazine (SSD)1%	5 – 15 drops (depending on dog size) q12h for up to 14 days	Otitis externa; especially involving Gram - bacteria; also has antifungal/yeast activity (SSD)
Enrofloxacin/Tris-EDTA (Compounded)		Use three times a day.	Mix 13 mL of the 100 mg/mL enrofloxacin injection with 120 mL of Tris/EDTA
Gentocin [®] <i>Ophthalmic</i> (Schering-Plough)	Gentamicin sulfate		
Silver sulfadiazine (Compounded)	Silver sulfadiazine	0.5 mL two to three times a day for 14 days.	Mix 1 part commercial cream with 1 to 9 parts of water. Rarely can cause hypersensitivity or irritancy. May be good for resistant <i>Pseudomonas</i> otitis externa.

Antimicrobial (Antifungal) Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Clotrimazole Solution (VET Solutions)	Clotrimazole 1%, chloroxylonol		
Conofite Solution [®] (Schering-Plough)	Miconazole nitrate 1%		
Otomax [®] (Schering-Plough); DVMax [®] (DVM) Tri-Otic [®] (Med-Pharmex) OtoSooth [®] (RXV) Otibiatic [®] (Butler) Gentizol [®] (VetOne) Malotic [®] (Vedco)	Gentamicin 0.3%, betamethasone 0.1%, clotrimazole 1%	2 – 12 drops (depending on ear size) q12h	Bacterial (<i>Pseudomonas</i>), allergic, fungal otitis
Panalog [®] (Fort Dodge) Derma 4 Ointment [®] (Pfizer) Dermagen Ointment [®] (Butler) Dermalone Ointment [®] (Vedco) Quadritop [®] <i>Ointment</i> (Vetus)	Neomycin 0.25%, thiostrepton, triamcinolone 0.1%, nystatin 100,000 U/ml	2 – 12 drops (depending on ear size) q12h	Bacterial, yeast or allergic otitis
Tresaderm [®] (Merial)	Neomycin 0.25%, dexamethasone 0.1%, thiabendazole 4%	2 – 12 drops (depending on ear size) q12h up to 7 days	

Corticosteroid + Antimicrobial Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Panalog [®] (Fort Dodge) Derma 4 Ointment [®] (Pfizer) Dermagen Ointment [®] (Butler) Dermalone Ointment [®] (Vedco) Quadritop [®] <i>Ointment</i> (Vetus)	Neomycin 0.25%, thiostrepton, triamcinolone 0.1%, nystatin 100,000 U/ml	2 – 12 drops (depending on ear size) q12h	Bacterial, yeast or allergic otitis
Tresaderm [®] (Merck)	Neomycin 0.25%, dexamethasone 0.1%, thiabendazole 4%	2 – 12 drops (depending on ear size) q12h	Bacterial, yeast or allergic otitis
Gentocin Otic Solution [®] (Schering); Betagen [®] <i>Otic Solution</i> (Med-Pharmex) Genone Otic Solution [®] (VetOne) Gentaotic [®] (Butler) Gentoved Otic Solution [®] (Vedco)	Gentamicin 3 mg/ml Betamethasone 1 mg/ml	2 – 12 drops (depending on ear size) q12h for 7-14 days	Bacterial (<i>Pseudomonas</i>), allergic otitis
MoMetaMax [®] <i>Otic Suspension</i> (Schering-Plough)	Per gram: Gentamicin 3 mg, mometasone 1 mg, clotrimazole 10 mg		

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Otomax [®] (Schering-Plough) DVMMax [®] (DVM) Tri-Otic [®] (Med-Pharmex) OtoSooth [®] (RXV) Otibiolic [®] (Butler) Gentizol [®] (VetOne) Malotic [®] (Vedco)	Gentamicin 0.3%, betamethasone 0.1%, clotrimazole 1%	2 - 12 drops (depending on ear size) q12h	Bacterial (<i>Pseudomonas</i>), allergic, fungal otitis
Quadritop [®] Ointment (Vetus)	Nystatin, neomycin sulfate, thiostrepton, triamcinolone acetate		
Topagen [®] Ointment (Schering-Plough)	Gentamicin sulfate, betamethasone valerate		
Tritop [®] (Pfizer)	Neomycin sulfate, isoflupredone acetate, tetracaine hydrochloride		

Antiparasitic Preparations

Trade Name (Manufacturer)	Active Ingredients	Dose	Notes
Acarexx [®] (Idexx)	0.01% Ivermectin	0.5 ml in each ear; repeat one time if necessary	For ear mites in cats
Cerumite [®] (Evsco)	Pyrethrins 0.05%, squalene 25%	2 - 12 drops (depending on ear size) q12h for 7-10 days	For ear mites
Milbemite [®] (Novartis)	Milbemycin oxime 0.1%	Apply entire contents of tube in external ear canal; one tube per ear	For ear mites in cats
Otomite Plus [®] (Virbac); Mita-Clear [®] (Pfizer)	Pyrethrins 0.15%, technical piperonyl butoxide 1.5%, N-oB dicarboximide 0.5%, Di-n-P isoinchomeronate 1%	Clean ear, instill enough to wet ear canal and massage. Retreat in 7 days	For ear mites

Small Animal Therapeutic Diets

The following tables are adapted from the Nutrition Support Service website <http://vet.osu.edu/nssvet.htm> at The Ohio State University Veterinary Hospital and were provided by Michelle DuMond, RVT and Dr. C.A. Tony Buffington. The diet manual found on the website is searchable and results can be sorted by a variety of dietary parameters. Because diets are constantly being adjusted, consult this website for the most current information.

Diet Manual

The following tables contain some nutrient parameters of the veterinary foods available in our hospital (Ohio State). The diets are classified as veterinary foods because they are to be used only under veterinary supervision. Commercially available foods also may be appropriate for some of the conditions listed (as described where appropriate in the tables). The tables are based on the most commonly recognized nutrient modifications for a particular disease. This format was chosen because veterinarians commonly make the diagnosis, decide on necessary nutrient modifications, then choose the most appropriate diet for their particular patient. Some foods are used for more conditions than are mentioned in the tables.

All tables contain a title, brief introduction if necessary, table of indications, contraindications, major nutrient modifications, and commercial substitutions if available. Table columns include:

- **DIET**—the type, canned or dry, and the name of the diet.
- **MFG.**—the manufacturer of the diet.
- **UNIT**—the unit of feeding, can for canned foods, cup for dry foods.
- **WEIGHT**—the net weight, in grams of the unit.
- **ENERGY**—the number of kilocalories (kcal) contained in each unit.
- **NUTRIENT AMOUNT PER 100 KCAL**—the grams of Protein, Fat, Carbohydrate (CHO). Fiber and Water, and milligrams (mg) of Calcium (Ca), Phosphorus (P), Sodium (Na), Potassium (K), and Magnesium (Mg) contained in 100 kcal of each diet as fed.

Foods formulated for calculolysis or prevention of urate (U), struvite (S) or oxalate (O) uroliths will include these columns. Diets with these potential attributes are signified by a “Y”.

To estimate the % of kcal as protein, or carbohydrate, multiply the grams by 4; for fat multiply by 9.

All data was obtained from manufacturer’s advertising literature available in the Autumn of 2007.

The data in the tables can be used to compare the nutrient content of different diets and, to compare nutrient content of a diet with the nutrient needs of a patient:

To compare diets:

Of similar moisture content and energy density, one can use the amount of nutrient per unit as fed—AAFCO regulations require that minimum percentages of protein and fat, and maximums for moisture and fiber, be reported on all pet foods.

Of differing moisture content (e.g., dry vs. canned) and similar energy density, one can use the amount of nutrient per unit dry matter. For example, a dry diet containing 20% protein and 9% water (=91% dry matter) on an as fed basis contains $20/91 \times 100 = 22\%$ protein on a dry matter basis, whereas a canned diet containing 5% protein and 77% water (=23% dry matter) on an as fed basis contains $5/23 \times 100 = 22\%$ protein on a dry matter basis.

Of differing energy density (e.g., high vs. low fat), one can use the amount of nutrient per 100 kcal. For example, a diet containing 25% protein and 7% fat on a dry matter basis contains 8 grams of protein per 100 kcal, whereas a diet containing 25% protein and 21% fat on a dry matter basis contains only 5 grams of protein per 100 kcal.

To compare nutrient content of a diet with the nutrient needs

of a patient, use the amount per unit body weight per day - because many veterinary foods contain restricted amounts of some nutrients, one must compare the number of grams of nutrient in the amount of food consumed with the needs of the animal to ensure that deficiencies are avoided. This is of practical concern for protein and sodium. For example, the minimum protein intake to sustain protein reserves in dogs is approximately 1 gram per pound per day. If a dog with advanced renal failure consumes 20 kcal per pound body weight per day, the diet would need to contain at least 5 grams per 100 kcal to provide enough protein to meet the dog’s needs. If the dog consumed 30 kcal per pound body weight per day, only 3.3 grams protein per 100 kcal diet would be necessary.

Because diet therapy for a number of diseases consists of restriction of nutrient intake, and because many (most?) patients with nutrient-sensitive diseases are older and don’t eat much, the risk of nutrient deficiencies must be considered. This is particularly true when the therapy is anticipated to continue for months or years. For these reasons, estimates of daily minimum intakes of some essential nutrients (amount per pound body weight) for adult, average-sized pets are presented below:

Nutrient	Dog	Cat
Energy	10 kcal	
Water	10 mL	
Protein	1 gram	2 gram
Sodium	10 mg	
Phosphorus	20 mg	

Veterinary foods often are sold as containing “high” or “low” levels of some nutrients. Currently, no generally accepted definition of these terms exists. My own definitions, many extrapolated from humans, follow:

Definition of “High” and “Low” Nutrient Densities

Nutrient	Dog	Cat
Low Calorie	< 3 kcal/gm dry matter	< 3 kcal/gm dry matter
High Calorie	>4.5 kcal/gm dry matter	>4.5 kcal/gm dry matter
Low Protein	<5 gm/100 kcal	<7 gm/100 kcal
High Protein	>8 gm/100 kcal	>10 gm/100 kcal
Low Fat	<2 gm/100 kcal	<2 gm/100 kcal
High Fat	>5 gm/100 kcal	>5 gm/100 kcal
Low Fiber	<0.25 gm/100 kcal	<0.25 gm/100 kcal
High Fiber	>1.5 gm/100 kcal	>1.5 gm/100 kcal
Low sodium	<100 mg/100 kcal	<100 mg/100 kcal

General feeding suggestions: Remember, It is always better for a patient to eat some of the “wrong” diet than none of the “right” diet!

1. Introduce diet gradually, once the patient’s condition is improving, to avoid creating a learned aversion, which is the association of an adverse stimulus with a novel diet. If one intends to feed a particular diet long-term, it should be introduced when the patient is feeling better so it is associated with feelings of improving health.
2. Amount- use the “Energy needs of sedentary dogs and cats” graph for initial guidelines, or offer ~20 kcal per pound body weight per day to cats and most dogs (~10 kcal/pound if > ~100 pounds), adjusting intake as necessary to maintain a moderate body condition.
3. Follow instructions in the section (see website) entitled “treating inappetence” when patient food intake falls below the above intake estimates.

Manufacturer Abbreviations:

Overdose and Toxin Exposure Decontamination Guidelines

CAMILE DECLEMENTI, VMD, DABT
ASPCA ANIMAL POISON CONTROL CENTER

All patients should be stabilized prior to attempting decontamination. Once stabilization has been accomplished, decontamination can be considered to prevent additional exposure to the toxicant. The specific method of decontamination that is chosen in each case must be guided by the species exposed and exposure circumstances. When a patient is exposed to a potentially dangerous substance by ingestion, the clinician has many options for decontamination including dilution, induction of emesis, lavage, the use of adsorbents, cathartics, and administration of enemas. In many cases, the best treatment plan will include more than one of these methods.

Dilution using a small amount of milk or water is recommended in cases where irritant or corrosive materials have been ingested. A dose of 2–6 mL/kg is suggested (Mathews, 2006), which for an average-sized cat, would be approximately only 1–2 teaspoons. Using only a small amount is important since excessive amounts could lead to vomiting and re-exposure of the esophagus to the damaging material (Rosendale, 2002). Juicy fruits and vegetables can be fed to accomplish dilution in some patients, especially birds and reptiles. Dilution is not appropriate in patients that are at an increased risk for aspiration, including those that are actively seizing or obtunded (Rosendale, 2002). Dilution with milk, yogurt and cottage cheese has been useful in cases of oral irritation following ingestion of plants containing insoluble calcium oxalate crystals (Philodendron species, for example) (Means, 2004).

Emetics are usually most effective if used within 2–3 hours after the ingestion (Rosendale, 2002) but in some cases, emesis may be effective even after that time frame. If the substance ingested could coalesce to form a bezoar in the stomach or a timed-released medication was ingested, emesis may be effective later than 3 hours after the ingestion. Chocolate (Albretsen, 2004) and chewable medications are examples of products that may form bezoars. Emetics generally empty 40–60% of the stomach contents (Beasley and Dorman, 1990). Feeding a small moist meal before inducing vomiting can increase the chances of an adequate emesis.

Animals that are able to vomit safely include dogs, cats, ferrets, and potbelly pigs. Emetics should not be used in birds, rodents, rabbits, horses or ruminants. Rodents are unable to vomit. Rabbits have thin-walled stomachs putting them at risk for gastric rupture if they vomit (Donnelly, 2004).

Induction of emesis is **contraindicated** with ingestion of corrosive agents including alkalis and acids. The protective epithelial lining of the esophagus may be damaged initially when one of these products is swallowed. The muscular layer of the esophagus may be exposed and at risk for ulceration, perforation and scarring if vomiting does occur (Beasley and Dorman, 1990). Emesis is also not recommended after petroleum distillate ingestion due to the risk of aspiration. The clinician must also take into account when deciding whether to induce emesis, any pre-existing conditions of the patient that can cause vomiting to be hazardous including severe cardiac disease or seizure disorder. In all instances, the attending veterinarian must carefully weigh the benefits of emesis against the risks. Emesis is not appropriate if the animal has already vomited or is exhibiting clinical signs such as coma, seizures or recumbency, which make emesis hazardous. Additionally, if the patient has ingested a stimulant and already

agitated the additional stimulation of vomiting could lead to seizures (Rosendale, 2002).

Hydrogen peroxide, apomorphine hydrochloride and xylazine hydrochloride are routinely used emetics in the veterinary clinical setting. Please see the monographs in the text for additional information on using these as emetics. Other products have been recommended by various sources as emetics, including table salt, dishwashing liquid, syrup of ipecac and powdered mustard. They are not as effective as hydrogen peroxide, xylazine or apomorphine, and salt and syrup of ipecac may cause significant adverse effects. Table salt (sodium chloride) has been associated with hypernatremia and CNS dysfunction (Beasley and Dorman, 1990) and there are concerns that syrup of ipecac can be cardiotoxic (Rosendale, 2002). Human pediatricians no longer routinely recommend syrup of ipecac for home use and The American Association of Poison Control Centers reported in 2001 that the use of ipecac in human exposures has fallen by more than 95% over a 15-year period (Shannon, 2003).

Lavage can be considered in cases where emesis is contraindicated, not possible or has been unsuccessful. For example, lavage is an option if the patient is agitated, seizing or recumbent or has other health concerns, such as recent abdominal surgery, that increase the risks associated with induction of emesis. Lavage should also be considered in rabbits and rodents, which are unable to vomit safely. Lavage is unlikely to be as effective as emesis (Beasley and Dorman, 1990) and is associated with significant potential risks (Rosendale, 2002). For these reasons, it should not be chosen routinely as a decontamination method over emesis. Lavage should also not be used to remove caustic materials or volatile hydrocarbons for the same reasons emesis is **contraindicated** in such cases (Rosendale, 2002).

The patient should be under general anesthesia when performing gastric lavage unless the patient is comatose. In all instances, a cuffed endotracheal tube should be in place to prevent aspiration. If the patient is a species with cheek pouches, the cheek pouches should be emptied gently with a finger or swab prior to the lavage. Risks associated with gastric lavage include esophageal or stomach damage or perforation, electrolyte abnormalities, hypothermia and the accidental placement of the tube in the trachea and the instillation of fluid into the patient's lungs (Rosendale, 2002).

Adsorbents may be utilized instead of or in addition to or lavage to prevent further systemic absorption of a toxicant. These agents act by adsorbing to a chemical or toxicant in the gastrointestinal tract and facilitating its excretion in the feces. Activated charcoal is the most commonly used adsorbent.

Activated charcoal is composed of large porous particles that adsorb to and therefore trap a wide range of organic compounds within the gastrointestinal tract. It is created from materials such as coal, wood, rye starch and coconut shells through a process using acid and steam treatments. The surface binding area of activated charcoal is large, in the range of 900–1500 m²/g (Rosendale, 2002). Charcoal tablets and capsules which are used to control flatulence and bloating are not likely to be as effective as the commercially prepared products (Buck and Bratich, 1986). The concentration of the capsules is often low and the binding area smaller.

Repeated doses of activated charcoal should be considered in some instances, such as cases where toxicants undergo enterohepatic recirculation. In enterohepatic recirculation, the toxicant is first carried to the liver by either the portal vein, after absorption from the gastrointestinal tract, or via the systemic circulation. Once in the liver, the toxicant then enters the bile and is excreted into the gastrointestinal tract where it is again available for absorption. Examples of toxicants known to undergo this type of recirculation include ibuprofen, marijuana and digoxin.

Another instance where multiple doses of activated charcoal are appropriate is in the treatment of ivermectin toxicosis. Ivermectin is a substrate for the P-glycoprotein pump that transports drugs across cell membranes. This pump is found in various cells including intestinal epithelial cells and brain capillary endothelial cells. In the intestine, ivermectin is absorbed into the enterocyte. However, once in the cell, the P-glycoprotein pump acts to move the ivermectin back into the gastrointestinal lumen. This cycling allows the ivermectin molecules to have multiple opportunities to bind with the repeated doses of activated charcoal. Other P-glycoprotein substrates include loperamide, diltiazem and doxorubicin (Mealey, 2006).

When repeated doses are indicated, half the original dose should be given at 4–8 hour intervals (Peterson, 2006). It is important to mention that if medications are excreted in the bile, activated charcoal can be beneficial regardless of the route the medication was administered. Thus if a patient received an overdose of injectable ivermectin subcutaneously, activated charcoal will still be a very useful.

Administration of activated charcoal does carry some risks and it does not bind all compounds equally. Some chemicals that are not bound effectively include: ethanol, methanol, fertilizer, fluoride, petroleum distillates, most heavy metals, iodides, nitrates, nitrites, sodium chloride, and chlorate. Activated charcoal should not be given to animals that have ingested caustic materials. It is unlikely to bind them, and it can be additionally irritating to the mucosal surfaces and make visualization of oral and esophageal burns difficult (Buck and Bratich, 1986). Activated charcoal can cause a false positive on an ethylene glycol test since propylene glycol is found in many formulations. Additionally, the timing of the activated charcoal administration should be taken into account when deciding on dosing of other oral medications since the charcoal can also bind them.

Activated charcoal administration carries a significant risk of aspiration. If a patient does aspirate the charcoal, the prognosis is poor hence proper placement of the stomach tube and a protected airway is a must in symptomatic patients. Constipation and black bowel movements are possible making it difficult to determine if melena is present. If the activated charcoal sits within the gastrointestinal tract for a significant period of time, it may release the compound it has adsorbed. It is, for this reason, that activated charcoal is frequently administered with a cathartic. Many commercially available preparations do contain a cathartic such as sorbitol.

Hypernatremia is another possible adverse effect of activated charcoal administration. In humans, hypernatremia has been reported primarily in children when multiple doses of a charcoal-sorbitol mixture were administered. The mechanism of hypernatremia is attributed to a water shift from the intracellular and extracellular spaces into the gastrointestinal tract as a result of the osmotic pull of the sorbitol cathartic (Allerton and Strom, 1991). The ASPCA Animal Poison Control Center (APCC) has also received reports of elevated serum sodium following activated charcoal administration in dogs. Hypernatremia appears to be reported more often in small dogs receiving multiple doses of activated charcoal, but it has also been reported in large dogs and in cases receiving only a single dose. Furthermore, unlike the human reports, elevated serum sodium has also been noted in cases where no cathartic was present in the charcoal (APCC unpublished data). Perhaps one of the other components of the product is also osmotically active. In these cases, the APCC has found that administration of a warm water enema is very effective at lowering the serum sodium and controlling the resultant central nervous system effects.

Cathartics enhance elimination of substances, including admin-

istered activated charcoal, by promoting their movement through the gastrointestinal tract. Activated charcoal only binds to toxicants by weak chemical forces, so without cathartics the bound toxicant can eventually be released and reabsorbed (Rosendale, 2002). When used with activated charcoal, the cathartic is given immediately following or mixed with the charcoal. Cathartics are **contraindicated** if the animal is dehydrated, has diarrhea, if ileus is present, or if intestinal obstruction or perforation are possible (Peterson, 2006).

There are bulk, osmotic, and lubricant cathartics. The most commonly used bulk cathartic is psyllium hydrophilic mucilloid (e.g., *Metamucil*®). Another bulking cathartic that can be used in dogs and cats is unspiced canned pumpkin. In birds and reptiles, diluted peanut butter, fruit or vegetables can also be used as bulking agents. Timothy hay can be utilized in rabbits. Osmotic cathartics have limited absorption from the gastrointestinal tract so they are able to pull water into the gastrointestinal tract, thereby increasing the fluid volume and stimulating motility to hasten expulsion in the feces.

There are saline and saccharide osmotic cathartics. Sorbitol is the most commonly used saccharide osmotic cathartic; it is the cathartic of choice and is frequently combined with activated charcoal in commercially prepared charcoal products. The saline cathartics include sodium sulfate (Glauber's salts) and magnesium sulfate (Epsom salts). Saline cathartics should **not** be used in patients with renal insufficiency or in birds or reptiles.

Of the lubricant cathartics, mineral oil is the most often used. Mineral oil is **not** recommended following activated charcoal administration as the mineral oil may render the charcoal less effective (Buck and Bratich, 1986; Galey, 1992). Since all cathartics alter the water balance in the gastrointestinal tract, electrolyte abnormalities, especially hypernatremia, are a potential risk to their use. Hydration status should be monitored frequently and fluids administered, intravenously or via an enema, as needed.

Enemas may be indicated when elimination of toxicants from the lower gastrointestinal tract is desired (Beasley and Dorman, 1990). Medications formulated as extended-release or controlled-release are absorbed from the entire gastrointestinal tract, including the colon (Buckley et al., 1995). An enema can be used to move those medications through the colon quickly and lessen additional systemic effects. The general technique is to use plain warm water or warm soapy water. Phosphate enema solutions should be avoided due to the risk of electrolyte and acid-base disturbances (Beasley and Dorman, 1990). In reptiles, enemas may be useful since ingested materials often lag for prolonged periods in the colon. Enemas are **not** recommended for birds since they already have a rapid gastrointestinal transit time.

ARCI UCGFS Classifications

The Association of Racing Commissioners International, Inc. is a non-profit corporation whose mission and vision is: To protect and uphold the integrity of the pari-mutuel sports of horse racing, dog racing and jai-alai through an informed membership, by encouraging forceful and uniform regulation, by promoting the health and welfare of the industry through various programs and projects.

The information in the monographs is taken from the Uniform Classification Guidelines for Foreign Substances and Recommended Penalties and Model Rule document (April 2005). The full document that includes suggested penalties may be found at: <http://www.arci.com/druglisting.pdf>.

The Uniform Classification Guidelines are intended to assist stewards, hearing officers and racing commissioners in evaluating the seriousness of alleged violations of medication and prohibited substance rules in racing jurisdictions. Practicing equine veterinarians, state veterinarians, and equine pharmacologists are available and should be consulted to explain the pharmacological effects of the drugs listed in each class prior to any decisions with respect to penalties to be imposed. The ranking of drugs is based on their pharmacology, their ability to influence the outcome of a race, whether or not they have legitimate therapeutic uses in the racing horse, or other evidence that they may be used improperly. These classes of drugs are intended only as guidelines and should be employed only to assist persons adjudicating facts and opinions in understanding the seriousness of the alleged offenses. The facts of each case are always different and there may be mitigating circumstances which should always be considered. These drug classifications will be reviewed frequently and new drugs will be added when appropriate.

Classification Definitions

Class 1: Stimulant and depressant drugs that have the highest potential to affect performance and that have no generally accepted medical use in the racing horse. Many of these agents are Drug Enforcement Agency (DEA) schedule II substances. These include the following drugs and their metabolites: Opiates, opium derivatives, synthetic opioids and psychoactive drugs, amphetamines and amphetamine-like drugs as well as related drugs, including but not limited to apomorphine, nikethamide, mazindol, pemoline, and pentylenetetrazol. Though not used as therapeutic agents, all DEA Schedule 1 agents are included in Class 1 because they are potent stimulant or depressant substances with psychotropic and often habituating actions.

Class 2: Drugs that have a high potential to affect performance, but less of a potential than drugs in Class 1. These drugs are 1) not generally accepted as therapeutic agents in racing horses, or 2) they are therapeutic agents that have a high potential for abuse. Drugs in this class include: psychotropic drugs, certain nervous system and cardiovascular system stimulants, depressants, and neuromuscular blocking agents. Injectable local anesthetics are included in this class because of their high potential for abuse as nerve blocking agents.

Class 3: Drugs that may or may not have generally accepted medical use in the racing horse, but the pharmacology of which suggests less potential to affect performance than drugs in Class 2. Drugs in this class include bronchodilators and other drugs with primary effects on the autonomic nervous system, procaine, anti-histamines with sedative properties and the high-ceiling diuretics.

Class 4: This class includes therapeutic medications that would be expected to have less potential to affect performance than those in Class 3. Drugs in this class includes less potent diuretics; anabolic steroids; corticosteroids; antihistamines and skeletal muscle relaxants without prominent central nervous system (CNS) effects; expectorants and mucolytics; hemostatics; cardiac glycosides and antiarrhythmics; topical anesthetics; antidiarrheals and mild analgesics. This class also includes the non-steroidal anti-inflammatory drugs (NSAIDs), at concentrations greater than established limits.

Class 5: This class includes those therapeutic medications for which concentration limits have been established by the racing jurisdictions as well as certain miscellaneous agents such as dimethylsulfoxide (DMSO) and other medications as determined by the regulatory bodies. Included specifically are agents that have very localized actions only, such as anti-ulcer drugs, and certain anti-allergic drugs. The anticoagulant drugs are also included.

Chemotherapy Protocols for Treatment of Neoplastic Diseases in Small Animals

The following are representative chemotherapy protocols that have been used to treat cancers in dogs, cats and ferrets. As therapeutic protocols for animals with neoplastic diseases will be continuously modified and chemotherapy treatment can include significant risks to both patients and veterinary staff, the practitioner is urged to consult with a veterinary oncologist before using these protocols. For more information on cancer chemotherapy and other dosages/protocols, see references such as: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

Canine Lymphoma Protocols

PREDNISONE ± CHLORAMBUCIL PROTOCOL

Generally used only for clients who cannot afford, or will not accept combination chemotherapy due to the risks of toxicity. May provide palliation with few risks of side effects. (Ogilvie 2006)

- a) Prednisone 40 mg/m² PO daily for 7 days, then every other day, alone or in combination with, chlorambucil 6 – 8 mg/m² PO every other day
- b) Collect CBC every 2-3 weeks to assure that myelosuppression is not occurring

COP (CYCLOPHOSPHAMIDE-VINCRIStINE-PREDNISONE) PROTOCOL

This protocol is administered on a 3-week (21 day) cycle for one year. It involves the use of vincristine, cyclophosphamide and prednisone. It is relatively inexpensive protocol with a low risk for toxicity; median remission time is about 7-9 months.

Week 1 (Day 1)

- A. Start prednisone at 1 mg/kg PO daily (continue throughout treatment)
- B. Vincristine at 0.75 mg/m² IV
- C. Cyclophosphamide at 200 – 250 mg/m² PO divided over 2-5 days.

Week 2 (Day 10)

- A. Vincristine injection 0.75 mg/m² IV

Week 3 (Day 21)

- A. Vincristine injection 0.75 mg/m² IV

Week 4 (Day 28)

- A. Vincristine injection 0.75 mg/m² IV
- B. Cyclophosphamide at 200 – 250 mg/m² PO divided over 2-5 days.

Week 7 (Day 49)

- A. Continue vincristine and cyclophosphamide as on week 4, decrease prednisone to every 48 hours

Monitor CBC's for myelosuppression 1 week after cyclophosphamide. Continue this cycle for one year. Begin to wean patient off prednisone after 12 months.

DOXORUBICIN PROTOCOL

This protocol is the most effective single agent regimen and has a relatively high remission rate and relatively few, serious or life-threatening toxicities (<5%).

1. **Induction Phase:** Doxorubicin 30 mg/M² (1 mg/kg for small dogs) given intravenously every 3 weeks for a 5-8 total treatments (Ogilvie 2006)
2. **Maintenance:** There is no maintenance therapy on this protocol. Animals completing the induction phase should be evaluated every 2-3 months.

■ SPECIAL PRECAUTIONS

1. Avoid extravasation of the drug. Use an indwelling catheter.
2. Reconstituted drug should be administered over a period of about 20 minutes into the side port of a freely running intravenous infusion of 0.9% NaCl.
3. Allergic reactions to the drug during administration may occur. They may be reduced by administering the drug over 20 minutes.
4. Doxorubicin can cause dose-dependent cardiotoxicity. Dogs should not receive more than 150 mg/M² cumulative total dose. Preexisting cardiac disease should be ruled out with a ECG and echocardiogram. Generally, dogs with severe arrhythmias or a decreased ventricular shortening fraction should not receive doxorubicin.
5. Anorexia, vomiting and/or diarrhea may be observed 2-5 days post therapy. Clinical signs vary from mild to severe.
6. Doxorubicin may cause severe neutropenia. A CBC should be evaluated 7 days following the first doxorubicin injection and prior to subsequent injections. If neutrophil count decreased to <1000/μl, the drug should not be administered and the dose reduced 10% at the next administration if the animal has no physical signs. If physical signs are present in conjunction with a low white count, the dose is reduced 25%.
7. Special precautions for handling doxorubicin:
 - a. Doxorubicin should be reconstituted in a biologic safety hood, if possible.
 - b. Skin contact with the drug should be avoided.
 - c. Care should be taken to avoid inhalation of the powder.
 - d. Double gloves should be worn when handling the drug.
 - e. Pregnant females should avoid handling or administering the drug.

WISCONSIN-MADISON PROTOCOL—SHORT

This is a five-drug protocol with a reported greater remission rate and duration (expected remission rate is 93%, median remission 13 months) than protocols using fewer drugs, but an increased risk for adverse effects.

- Week 1: Vincristine 0.7 mg/m² IV
Asparaginase 400 IU/kg IM
Prednisone 2 mg/kg PO once daily
- Week 2: Cyclophosphamide 250 mg/m² IV
Prednisone 1.5 mg/kg PO once daily
- Week 3: Vincristine* 0.7 mg/m² IV
Prednisone, 1.0 mg/kg PO once daily
- Week 4: Doxorubicin 30 mg/m² IV
Prednisone 0.5 mg/kg PO once daily
- Week 6: Vincristine* 0.7 mg/m² IV
- Week 7: Cyclophosphamide 250 mg/m² IV
- Week 8: Vincristine* 0.7 mg/m² IV
- Week 9: Doxorubicin 30 mg/m² IV
- Week 11: Vincristine* 0.7 mg/m² IV
- Week 13: Cyclophosphamide 250 mg/m² IV
- Week 15: Vincristine* 0.7 mg/m² IV
- Week 17: Doxorubicin 30 mg/m² IV
- Week 19: Vincristine* 0.7 mg/m² IV
- Week 21: Cyclophosphamide 250 mg/m² IV
- Week 23: Vincristine* 0.7 mg/m² IV
- Week 25: Doxorubicin 30 mg/m² IV

*For all treatments, administer 400 IU/kg of asparaginase with each vincristine injection until a remission is attained.

All treatments are discontinued after week 25 if in complete remission. A CBC should be performed prior to each treatment, if the neutrophils are less than 2000, wait 5-7 days and repeat CBC. If sterile hemorrhagic cystitis occurs on cyclophosphamide, discontinue and switch to Chlorambucil (1.4 mg/kg PO).

VELCAP-S PROTOCOL

This is another five-drug protocol with a reported greater remission rate and duration than protocols using fewer drugs, but an increased risk for adverse effects.

INDUCTION:

- Prednisone 40 mg/m² q24h PO for 7 days, then every alternate day. From week 12, taper by reducing dose by 1/2 each week until week 15; then discontinue.
- Doxorubicin 25 mg/m² IV on weeks 2 and 4;
- Vincristine 0.75mg/m² IV on weeks 1,2, 3, 7 & 12;
- Cyclophosphamide 250 mg/m² PO on weeks 7 & 12. If cystitis occurs, substitute with chlorambucil at 15 mg/m² PO daily for 4 consecutive days on same schedule;
- Asparaginase 10,000 IU/m² IM, to a maximum dose of 10,000 IU per administration on weeks 7, 8, & 9.

If relapse occurs <16 weeks after last treatment, repeat VELCAP-S (induction). If relapse occurs >16 weeks after last treatment, use VELCAP-S (maintenance).

MAINTENANCE:

- Prednisone 40 mg/m² q24h PO for 7 days, then every alternate day.
- Doxorubicin 25 mg/m² IV on weeks 2 and 4, 18, & 27;
- Vincristine 0.75mg/m² IV on weeks 1,2, 3, 7 & 12, 15,18, 21 & 27;
- Cyclophosphamide 250 mg/m² PO on weeks 7, 12, 15, 21, & 24. If cystitis occurs, substitute with chlorambucil at 15 mg/m² PO daily for 4 consecutive days on same schedule;
- Asparaginase 10,000 IU/m² IM, to a maximum dose of 10,000 IU per administration on weeks 7, 8, 9, 24, & 25.

From week 30, repeat weeks 12-18 every 9 weeks until week 52, then treatments are given every 4 weeks to week 78. (Moore, Cotter et al. 2001)

Other Canine Protocols

CANINE SARCOMA & CARCINOMA TREATMENT PROTOCOL "AC"

This protocol is indicated for the treatment of thyroid and mammary carcinomas in the dog, either as primary therapy for non-resectable tumors or as adjuvant therapy following surgery.

- Doxorubicin: 30 mg/M² IV on day 1
- Cyclophosphamide: 50 mg/M² PO on days 3-6

Repeat every 21 days for a total of 3 cycles.

CANINE OSTEOGENIC SARCOMA ADJUVANT PROTOCOL

For use following limb amputation in dogs with osteogenic sarcoma

DAY 1: Doxorubicin 30 mg/m² IV over 20 minutes via catheter and fluids (see above)

DAY 7: Perform CBC

DAY 22 (3 weeks from initial doxorubicin dose): Carboplatin 300 mg/m². Place IV catheter and give via slow push without extra fluids

DAY 44 (3 weeks from initial carboplatin dose): Recheck CBC; if WBC is > 4000 (neutrophils >3500) and platelets > 60,000 (and the CBC values drawn on day 7 were above these parameters) give additional doxorubicin dose of 30 mg/m² (as above).

Repeat as above every 3 weeks alternating doxorubicin and carboplatin until a total of 3 doses of each have been given.

MAST CELL TUMOR PROTOCOL

- a) For mast cell tumors after surgical removal: vinblastine at 2 mg/m² IV, weekly for four weeks then every two weeks for eight weeks. Prednisolone is given concurrently starting at 2 mg/kg/day, tapering to 0.5 mg/kg day. (Davies, Wyatt et al. 2002)

Feline Lymphoma Protocols

NOTE: Cats with acute life-threatening lymphoma (anterior mediastinal with respiratory compromise, or central nervous system disease) may be additionally treated with radiation therapy of the affected area.

COPLA PROTOCOL

- a) Cyclophosphamide 25 mg tablet PO twice weekly for 42 days (6 weeks);
 b) Vincristine 0.1 mg IV, starting day 1, then every 7 days for 42 days (6 weeks);
 c) Prednisone 5 mg PO once daily for 7 days; then 5 mg PO every other day until relapse or adverse steroid effects, in which case taper dose and discontinue;
 d) L-asparaginase 400 U/kg SC on days 1 and 8;
 e) Doxorubicin) 20 – 25 mg/m² IV on weeks 6, 9, and 12.

CBC's and lymph node measurements should be obtained weekly beginning on day 8 in order to modify treatment, if deemed necessary (Kitchell 2005b)

COP PROTOCOL

- a) Cyclophosphamide 25 mg tablet PO twice weekly for 42 days (6 weeks);
 b) Vincristine (Oncovin) 0.1 mg IV every 7 days for 42 days (6 weeks);
 c) Prednisone 5 mg PO once a day for 1 week; then 5 mg PO every other day until relapse or adverse steroid effects, in which case taper dose and discontinue.

CBC's and lymph node/mass measurements should be obtained weekly in order to modify treatment, if deemed necessary (Kitchell 2005b)

COAP PROTOCOL

- a) Cyclophosphamide 25 mg tablet PO twice weekly for 42 days (6 weeks);
 b) Vincristine (Oncovin) 0.1 mg IV every 7 days for 42 days (6 weeks);
 c) Cytarabine (cytosine arabinoside) 25 mg per cat SC, divided into three doses per day for 2 days
 d) Prednisone 5 mg PO once a day for 1 week; then 5 mg PO every other day until relapse or adverse steroid effects, in which case taper dose and discontinue. (Kitchell 2005b)

Ferret Lymphoma Protocols**FERRET LSA PROTOCOL**

- Week 1: Vincristine 0.07 mg/kg IV
 Week 2: Cytoxan at 10 mg/kg PO
 Week 3: Vincristine 0.07 mg/kg IV
 Week 4: Methotrexate at 0.5 mg/kg subcutaneous
 Week 5: Vincristine 0.07 mg/kg IV
 Week 6: Cytoxan at 10 mg/kg PO
 Week 7: Vincristine 0.07 mg/kg IV
 Week 8: Methotrexate at 0.5 mg/kg subcutaneous

After week 7, the same protocol is used, but the treatments are spaced out to every two weeks, rather than every week. Every one to two weeks, a blood cell count should be checked to ensure that Dino is not being immunosuppressed by the treatment, which is a possible side effect.

Conversion Tables for Weight in Kilograms to Body Surface Area (m²)

The following tables are derived from the equation:

$$\text{Approximate surface area in m}^2 = \frac{10.1 (10.0 \text{ for cats}) \times (\text{weight in grams})^{2/3}}{10000}$$

Dogs

Abbreviations Used in Prescription Writing

A warning and the strange case of S.I.D.: Although prescription abbreviations are used throughout many references and they are generally fairly well recognized, they do increase the potential for mistakes to occur. When writing a prescription, this author recommends writing out the directions in plain English and avoiding the use of abbreviations entirely. If abbreviations are to be used, definitely avoid q.d., q.o.d., q.i.d. and s.i.d. because they can be easily confused with other abbreviations.

S.I.D. is an abbreviation virtually unknown to health professionals outside of veterinary medicine and the vast majority of pharmacists have never seen it. **S.I.D. should be eliminated from all veterinary usage and replaced with “once a day”.** The additional time to write out “once a day” versus “SID” is approximately 3 seconds, but by doing so, a potentially serious, avoidable error could be prevented.

a.c.	before meals
a.d.	right ear
a.s.	left ear
a.u.	both ears
amp.	ampule
b.i.d.	twice a day
c.	with
cap.	capsule
cc	cubic centimeter
disp.	dispense
g or gm	gram
gtt(s).	drop(s)
h.	hour
h.s.	at bedtime
IM	intramuscular

IO	intraosseous
IP	intraperitoneal
IV	intravenous
lb.	pound
m2	meter squared
mg.	milligram
ml. or mL	milliliter
o.d.	right eye
o.s.	left eye
o.u	both eyes
p.c.	after meals
p.o	by mouth
p.r.n.	as needed
q.	every
q4h, etc	every 4 hours
q.i.d.	four times a day
q.o.d.	every other day
q.s.	a sufficient quantity
q4h	every 4 hours, etc.
s.i.d.	once a day
Sig:	directions to pt.
stat	immediately
SubQ, SQ, SC, Subcut	subcutaneous
susp.	suspension
t.i.d.	three times a day
tab	tablet
Tbsp., T	tablespoon (15 ml)
tsp., t	teaspoon (5 ml)
Ut dict	as directed

Solubility Definitions

The following definitions are used throughout the book in the chemistry section for each agent:

Descriptive Term	Parts of Solvent for 1 Part of Solute
Very Soluble	Less than 1
Freely Soluble	From 1 to 10
Soluble	From 10 to 30
Sparingly Soluble	From 30 to 100
Slightly Soluble	From 100 to 1000
Very Slightly Soluble	From 1000 to 10,000
Practically Insoluble, or Insoluble	More than 10,000

Conversion: Weights; Temperature; Liquids

1 pound (lb) = 0.454 kg = 454 grams = 16 ounces
 1 kilogram (kg) = 2.2 pounds = 1000 grams
 1 grain (gr.) = 64.8 mg (often rounded to 60 or 65 mg)
 1 gram = 15.43 grains = 1000 mg
 1 ounce = 28.4 grams
 1 milligram (mg) = 1000 mcg (µg)
 1 microgram (mcg or µg) = 1000 nanograms (ng)

TEMPERATURE CONVERSION:

$9 \times (^{\circ}\text{C}) = (5 \times ^{\circ}\text{F}) - 160$
 $^{\circ}\text{C to } ^{\circ}\text{F} = (^{\circ}\text{C} \times 1.8) + 32 = ^{\circ}\text{F}$
 $^{\circ}\text{F to } ^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times 0.555 = ^{\circ}\text{C}$

LIQUID MEASURE:

1 gallon (gal.) = 4 qts. = 8 pts. = 128 fl. oz. = 3.785 liters = 3785 ml
 1 quart (qt) = 2 pints = 32 fl. oz. = 946 ml
 1 pint = 2 cups = 16 fl. oz. = 473 ml
 1 cup = 8 fl. oz. = 237 ml = 16 tablespoons
 1 tablespoon = 15 mL = 3 teaspoons
 1 teaspoon = 5 mL
 4 liters = 1.057 gals.
 1 liter = 1000 mL = 10 deciliters
 1 deciliter (dl) = 100 ml
 1 milliliter (mL) = 1 cubic centimeter (cc) = 1000 microliters (µl; mcl)

Milliequivalents & Molecular Weights

Milliequivalents: The term milliequivalents (mEq) is usually used to express the quantities of electrolytes administered to patients. A mEq is 1/1000 of an equivalent (Eq). For pharmaceutical purposes an equivalent may be thought of as equal to the equivalent weight of a given substance. This, in practical terms, is the molecular weight of the substance divided by the valence or the radical. For example:

How many milligrams are equivalent to 1 mEq of potassium chloride (KCl)?

1. Determine the equivalent weight = gram atomic weight ÷ valence; Molecular weight of KCl = 74.5; Valence = 1 (K⁺; Cl⁻); Equivalent weight = 74.5 ÷ 1 = 74.5 grams
2. Determine the mEq weight: Equivalent weight ÷ 1000; 74.5 ÷ 1000 = 74.5 mg = 1 mEq of KCl = 1 mEq of K⁺ & 1 mEq of Cl⁻

If the substance would have been CaCl₂, the process would be identical using the gram molecular weight of CaCl₂ (MW 111 if anhydrous; 147 if dihydrate) and a valence of 2.

Listed below are several commonly used electrolytes with their molecular weights and valences in parentheses:

Electrolyte	Molecular Weight (valence)
Sodium Chloride	58.44 (1)
Sodium Bicarbonate	84 (1)
Sodium Acetate, anhydrous	82 (1)
Sodium Acetate, trihydrate	136 (1)
Sodium Lactate	112 (1)
Potassium Chloride	74.55 (1)
Potassium Gluconate	234.25 (1)
Calcium Gluconate	430.4 (2)
Calcium Lactate, anhydrous	218.22 (2)
Calcium Chloride, anhydrous	111 (2)
Calcium Chloride, dihydrate	147 (2)
Magnesium Sulfate, heptahydrate	246.5 (2)
Magnesium Sulfate, anhydrous	120.4 (2)
Magnesium Chloride, anhydrous	95.21 (2)
Magnesium Chloride, hexahydrate	203.3 (2)

“Normal” Vital Signs

Temperature	Celsius (°C)	Fahrenheit (°F)
Dog	37.5-39.2	99.5–102.5
Cat	37.8-39.5	100–102.5
Ferret	37.8-39.2	100–102.5
Cattle, up to one year old	38.6-39.4	101.5–103.5
Cattle, over one year old	37.8-39.2	100–102.5
Horse, adult	37.2-38.5	99–101.3
Horse, foal	37.5-39.3	99.5–102.7
Goat	38.5-40.2	101.3–104.5
Sheep	38.5-40	101.3–104
Swine, piglet	38.9-40	102–104
Swine, adult	37.8-38.9	100–102
Rabbit	38.5-39.3	100.4–105

Temperature (Rectal): Temperatures will normally fluctuate over the course of the day. The following may increase body temperature: Time of day (evening), food intake, muscular activity, approaching estrus, during gestation, high external temperatures. The following may decrease body temperature: intake of large quantities of cool fluids, time of day (morning), and low atmospheric temperature. Small breed dogs tend to have higher normal temps than large breeds.

Pulse Rates	BPM
Cattle, calves	100–120
Cattle, adults	55–80
Cat, young	130–140
Cat, old	100–120
Dog, young	110–120
Dog, adult large breed	80–120
Ferret	300
Goat	70–120
Horse, adult	28–40
Horse, 3 months-2 years	40–80
Horse, foals-3 months	64–128
Rabbit	120–150
Sheep	66–115
Swine, young	100–130
Swine, adult	60–90

Pulse Rates (resting and healthy) in beats per minute (BPM). Pulse rates for very young animals are usually in the higher ranges and older animals in the lower ranges of those values listed.

Respiratory Rates	RPM
Cattle, young	15–40
Cattle, adults	10–30
Cats	20–30
Dog	15–30
Ferret	33–36
Horse	10–14
Swine	8–18
Rabbit	50–60
Sheep, Goat	10–30

Respiratory Rates (resting & healthy) respirations per minute

Estrus and Gestation Periods for Dogs & Cats

	Dog	Cat
Appearance of first estrus at the age of:	7–9 months	4–12 months
Estrous cycle in animals not served:	Mean = 7 months Range = every 5–8 months	Every 4–30 days (14–19 day model) if constant photoperiod
Duration of estrus period:	7–42 days (proestrus plus estrus)	2–19 days
First occurrences after parturition:	Pregnancy does not alter interval	7–9 days
Gestation Period	Mean = 63 days; Range 58–71 days	Mean = 63 days; Range 58–70 days

	Dog	Cat
Number of Young	8–12 Large Breeds 6–10 Medium Breeds 2–4 Small Breeds	4–6
Suckling Period	3–6 weeks	3–6 weeks

Conversion of Conventional Chemistry Units to SI Units

The Système Internationale d’Unités (SI), or the International System of Units was recommended for use in the health professions by the World Health Assembly in 1977. It is slowly being adopted in the United States and many journals now require its use. The following is an abbreviated table of conversion values for some of the more commonly encountered tests that may now be reported in SI Units.

Chemistry Units to SI Units	
Albumin	g/dl x 10 = g/L
Ammonia	µg/dl x 0.5872 = µmol/L
Bilirubin	mg/dl x 17.10 = µmol/L
Calcium	mg/dl x 0.2495 = mmol/L
Cholesterol	mg/dl x 0.02586 = mmol/L
CO ₂ pressure, pCO ₂	mmHg x 0.1333 = kPa
Creatinine	mg/dl x 88.4 = µmol/L
Glucose	mg/dl x 0.05551 = mmol/L
Lactate	mg/dl x 0.111 = mmol/L
Magnesium	mg/dl x 0.4114 = mmol/L
O ₂ pressure, pO ₂	mmHg x 0.1333 = kPa
Phosphorus	mg/dl x 0.3229 = mmol/L
Protein	g/dl x 10 = g/L
Urea Nitrogen	mg/dl x 0.7140 = mmol/L
Amylase	IU/L = U/L
AST (SGOT)	IU/L = U/L
ALT (SGPT)	IU/L = U/L
Lipase	IU/L = U/L
ALP	IU/L = U/L
SDH (Sorbitol)	IU/L = U/L

Bicarbonate, Chloride, CO₂ (total), Potassium, & Sodium do not require conversion from conventional to SI units.

Reference Laboratory Ranges

Note: The following reference ranges are as a general reference only; refer to the “normals” for the laboratory you are using

Chemistry: Canine, Feline, Bovine, Equine

Values are from: Marshfield Clinic Laboratories, Veterinary Diagnostic Service; 2007

Test	Units	Canine	Feline	Bovine	Equine
Glucose	mg/dl	75–45	56–153	50–79	52–121

Legally Importing Drugs for Compassionate Use into the USA

Drugs that are commercially available for companion (non-food) animals in other countries may be legally imported into the USA in which the following conditions apply:

- The drug does not pose a significant risk to animal or human health
- The drug is used to treat or prevent a serious disease or condition in an animal
- There is no other available source of that drug or alternative drug(s) that is judged by FDA-CVM veterinary staff to be an adequate substitute
- The request for importation is made by a licensed veterinarian within the context of a valid veterinarian-client-patient relationship
- A relatively small amount of drug is requested for import
- There is no active promotion or marketing of the drug in U.S. markets for the intended use of the product

For assistance with importing unapproved, but medically necessary veterinary drugs, please contact Mr. Mike Zimmerman, CVM/OSC/Division of Compliance (HFV-235), at phone (240) 276-9202, Fax (240) 276-9241, or by e-mail at michael.zimmerman@fda.hhs.gov

Prior approval must be obtained from the FDA's Center for Veterinary Medicine (FDA-CVM) before ordering these agents. There is no specific governmental application form. The FDA-CVM prefers that veterinarians send a letter of request for personal importation of a drug on business stationery by facsimile. The FDA needs the following information to fully evaluate the request:

- How the veterinarian learned of the existence of the drug/product
- Veterinarian's name, address and phone number
- Clinic name and address

- Client's name and address
- Patient name and nonfood species
- Name of drug
- Drug family or class
- Name and address of drug supplier
- Legal status of the drug in the foreign country
- Amount of drug to be imported—must be small, noncommercial quantities
- Disease condition to be treated
- Reason why an approved human or animal drug will not treat the disease condition
- Statement that the veterinarian will notify the animal owner that the drug is not approved, that the drug will not be used in any food animal, and that the veterinarian agrees to notify the FDA if there are any adverse reactions

Once completed, the letter should be faxed to: Mr. Mike Zimmerman, CVM/OSC/Division of Compliance (HFV-235), Fax (240) 276-9241.

If the CVM grants permission, the veterinarian will receive an FDA letter authorizing the personal importation of a foreign drug for a specific patient. The department can withdraw regulatory discretion at any time.

Veterinarians should retain a copy of the FDA letter for their records and send a copy to the supplier or customs broker; request that they include the letter with the shipping documents. Failure to have the letter with the shipping documents will delay (or halt) shipment should U.S. Customs and Border Protection intercept it.

A new letter must be sent each time for each request for each specific patient.

Two sources recommended to the author (Plumb) for arranging legal importation of veterinary drugs to US veterinarians include:

Systemic Drugs Sorted by Therapeutic Class or Major Indication

Where dosages are available for a given species, the following code is used in parentheses after the drug name:

A = Avian; Pet Bird
B = Bovine, Cattle
C = Cat, Feline
D = Dog, Canine
Fer = Ferret
H = Horse, Equine
L = Llama, Camelids
Po = Pocket Pets, Rabbits, Small Lab Animals
O = Ostrich, Ratite
R = Reptiles/Amphibians
Sh = Sheep/Goats; Ovine/Caprine
Sw = Swine, Pigs
Z = Wildlife/Zoo Animals

Note: As some drugs have multiple indications, there may not be a specific dosage listed for that indication for every species noted.

Antihistamines

Cetirizine (D, C)
Chlorpheniramine (D, C, Fer)
Clemastine Fumarate (D, C)
Cyproheptadine (D, C, H)
Diphenhydramine (D, C, Fer, Po, H, B)
Doxepin (D)
Hydroxyzine (D, C, Fer, H, A)
Meclizine (D, C, Po)
Promethazine (D, C)
Pyrilamine (D, B, H, Sh, Sw)
Trimeprazine (D)
Tripeleminamine (D, C, B, H, Sw)

Central Nervous System Drugs

(including antiinflammatories, analgesics, muscle relaxants)

CNS/RESPIRATORY STIMULANTS

Doxapram (D, C, Po, B, Sw, H)

ANALGESICS, OPIATE AGONISTS

Alfentanil (D)
Codeine Phosphate (D, C)
Fentanyl (D, C, Po)
Hydromorphone (D, C)
Meperidine (D, C, Fer, Po, Sh, Sw, B, H)
Morphine (D, C, Po, H, Sw, Sh)
Oxymorphone (D, C, Fer, H, Sw, P)
Sufentanil (D, C)

ANALGESICS, OPIATE AGONIST/ANTAGONISTS

Buprenorphine (D, C, Po, Fer, H)
Butorphanol (D, C, Fer, Po, B, H, A)
Pentazocine (D, Po, Fer, H, Sw)

NONSTEROIDAL ANTIINFLAMMATORY/

ANALGESIC AGENTS

Acetaminophen (D, Po)
Aspirin (D, C, Po, Fer, B, H, Sw, A)
Carprofen (D, C, Po, H, A)
Colchicine (D)
Dimethyl Sulfoxide (D, H)
Etodolac (D)
Firocoxib (D, H)
Flunixin (D, C, Fer, Po, B, H, A)
Ketoprofen (D, C, Po, H, A)
Ketorolac Tromethamine (D, Sh, Po)
Meclofenamic Acid (D, H, B)
Meloxicam (D, C)
Naproxen (D, Po, H)
Phenylbutazone (D, B, H, Sw),
Piroxicam (D, C, Po)
Tolfenamic Acid (D, C)

BEHAVIOR-MODIFYING AGENTS

Amitriptyline (D, C)
Buspirone (D, C)
Clomipramine HCl (D, C)
Clorazepate (D)
Fluoxetine (D, C)
Fluvoxamine
Imipramine (D, C)
Lorazepam (D, C)
Paroxetine HCl (D, C)
Pheromones (D, C, H)
Sertraline (D, C)

TRANQUILIZERS/SEDATIVES

Acepromazine (D, C, Fe, P, B, H, Sw, Sh)
Alprazolam (D, C)
Azaperone (Sw)
Chlordiazepoxide (D, C)
Detomidine (H, B, A)
Dexmedetomidine (D, C)
Diazepam (D, C, Po, A, B, H, Sw, Sh)
Doxepin (D)
Lorazepam (D, C)
Medetomidine (D, C, Po, Fer, A, R)
Midazolam (D, C, Po, A, H)
Promazine (D, C, B, H, Sw)
Romifidine (D, C, H)
Tiletamine/Zolazepam (D, C, Po, Fer, H, R, A, Z)
Xylazine (D, C, Fer, Po, B, H, Sh, Z)

ANESTHETIC AGENTS, BARBITURATES

Pentobarbital (D, C, Po, B, H, Sw, Sh)
Methohexital Sodium (D, C)
Thiopental (D, C, Po, B, H, Sw, Sh)

ANESTHETIC AGENTS, INHALANTS

Isoflurane (D, C, Po, R, A)
Halothane (D, C, P, H)
Methoxyflurane (D, C, B, Sh, Sw)
Sevoflurane

ANESTHETIC AGENTS, MISCELLANEOUS

Alfentanil (D)
Amantadine (D, C, H)
Fentanyl (D, C)
Ketamine (D, C, Po, Fer, B, H, Sw, Sh, R, A, Z)
Propofol (D, C, Po, R)

Sufentanil (D, C)
Tiletamine/Zolazepam (D, C, Po, Fer, H, A, Z)
Xylazine (D, C, Po, Fer, B, H, Sh, Z)

REVERSAL AGENTS

Atipamezole (D, Po, A, R)
Flumazenil (D, C)
Naloxone (D, C, Po, H)
Naltrexone (D, C)
Neostigmine (D, C, B, H, Sw, Sh)
Tolazoline (D, C, H, A, Sh, B, Z)
Yohimbine (D, Po, A, B, H, L, Z)

ANTICONSULSANTS

Bromides (D, C)
Clonazepam (D)
Clorazepate (D)
Diazepam (D, C, Po, A, B, H, Sw, Sh)
Felbamate (D)
Levetiracetam (D, C)
Lorazepam (D, C)
Phenobarbital (D, C, Fer, B, H)
Phenytoin (D, C, H)
Primidone (D, C)
Topiramate (D, C)
Valproic Acid (D)
Zonisamide (D)

MUSCLE RELAXANTS, SKELETAL

Atracurium (D, C, Po, H)
Baclofen (D)
Dantrolene (D, C, H, Sw)
Guaifenesin (D, B, H, Sw, Sh)
Methocarbamol (D, C, B, H)
Pancuronium (D, C, Po, Sw)
Succinylcholine (D, C, H)
Vecuronium (D)

Euthanasia Agents

Pentobarbital/Phenytoin (D, C)

Cardiovascular Agents

INOTROPIC AGENTS

Digoxin (D, C, Fer, Po, B, H, A)
Digitoxin (D, C, H)
Dobutamine (D, C, H)
Inamrinone Lactate (D, C)

ANTIARRHYTHMIC DRUGS

Amiodarone (D, H)
Disopyramide (D)
Lidocaine (D, C, H)
Mexiletine (D)
Procainamide (D, C, H)
Quinidine (D, C, H)
Tocainide (D)
Verapamil (D, C)

ANTICHOLINERGICS

Atropine (D, C, B, H, Po, Fer, Sw, Sh, A, R)
Glycopyrrolate (D, C, Fer, Po, H)
Hyoscyamine (D)

ACE INHIBITORS

Benazepril (D, C)
Captopril (D, C)
Enalapril (D, C, Fer)
Ramipril (D, C)

CALCIUM CHANNEL BLOCKING AGENTS

Amlodipine (D, C)
Diltiazem (D, C, Fer)
Verapamil (D, C)

VASODILATING AGENTS

Hydralazine (D, C, H)
Isosorbide (D, C)
Isoxsuprine (H)
Nitroglycerine (D, C, Fer)
Nitroprusside (D, C)
Sildenafil (D, C)

AGENTS USED IN TREATMENT OF SHOCK

Dobutamine (D, C, H)
Dopamine
Epinephrine (D, C, H, B, Sh, Sw)
Isoproterenol HCl (D, C, H)
Phenylephrine (D, C, H)

ALPHA-ADRENERGIC BLOCKING AGENTS

Phenoxybenzamine (D, C, H)
Prazosin (D, C)

BETA-ADRENERGIC BLOCKING AGENTS

Atenolol (D, C, Fer)
Carvedilol (D)
Esmolol (D, C)
Metoprolol (D, C)
Propranolol (D, C, Fer, H)
Sotalol HCl (D)

ANTIHYPERTENSIVE AGENTS

Nitroprusside (D, C)
Irbesartan (DS)

OTHER CARDIOVASCULAR AGENTS

Carnitine (D, C)
Taurine (D, C)

Respiratory Drugs
SYMPATHOMIMETICS

Albuterol (D, H)
Clenbuterol (H)
Ephedrine (D, C)
Epinephrine (D, C, H, B, Sh, Sw)
Isoproterenol HCl (D, C, H)
Pseudoephedrine HCl (D)
Terbutaline (D, C, H)

XANTHINES

Aminophylline/Theophylline (D, C, Fer, H)

ANTITUSSIVES

Codeine (D, C)
Butorphanol (D, C, Fer, Po, B, H, A)
Hydrocodone (D)

MUCOLYTICS

Acetylcysteine (D, C)

OTHER RESPIRATORY AGENTS

Cromolyn Sodium (H)
Ipratropium Br (H)
Zafirlukast (C)

Renal and Urinary Tract Agents
DIURETICS, CARBONIC ANHYDRASE INHIBITORS

Acetazolamide (D, C, B, H, Sh, Sw)
Dichlorophenamide (D, C)
Methazolamide (D)

DIURETICS, THIAZIDES

Chlorothiazide (D, B)
Hydrochlorothiazide (D, C, B)

DIURETICS, LOOP

Furosemide (D, C, Fer, Po, B, H, A, R)
Ethacrynic Acid (D, C)
Torsemide (D, C)

DIURETICS, POTASSIUM SPARING

Spironolactone (D, C)
Triamterene (D)

DIURETICS, OSMOTIC

Glycerine, Oral (D, C)
Mannitol (D, C, B, Sw, Sh, H)

AGENTS FOR URINARY INCONTINENCE/
RETENTION

Baclofen (D)
Bethanechol (D, C, H, R)
Ephedrine (D, C)
Flavoxate (D)
Imipramine (D, C)
Oxybutynin (D, C)
Phenoxybenzamine (D, C, H)
Phenylpropanolamine (D, C)
Pseudoephedrine HCl (D)

URINARY ALKALINIZERS

Sodium Bicarbonate (D, C, H, B, Sh, A)

URINARY ACIDIFIERS

Methionine (D, C, B, H)
Ammonium Chloride (D, C, H, B, Sh)

AGENTS FOR UROLITHIASIS

Acetohydroxamic Acid (D)
Allopurinol (D, C, A)
Ammonium Chloride (D, C, H, B, Sh)
Citrate Salts (D)
Methionine (D, C, B, H)
Tiopronin (D)

MISCELLANEOUS RENAL/URINARY AGENTS

Amitriptyline (C)
Pentosan (C)
Probenecid (R)

Gastrointestinal Agents
ANTIEMETIC AGENTS

Chlorpromazine (D, C, B, H, Sw, Sh)
Dimenhydrinate (D, C)
Diphenhydramine (D, C, B)
Granisetron (D, C)
Maropitant (D, C)
Meclizine (D, C, Po)
Mirtazapine (D, C)
Metoclopramide (D, C, Po, H)
Ondansetron (D, C)
Prochlorperazine (D, C)
Promethazine (D, C)

ANTACIDS

Aluminum Hydroxide (D, C, Po, B, H)
Calcium Salts, Oral (D, C, B, H, Sh, Sw, A, R)
Sodium Bicarbonate (D, C, H, B, Sh, A)

H-2 ANTAGONISTS

Cimetidine (D, C, Fer, Po, B, H, Sw, R)
Famotidine (D, C, Fer, H)

Nizatidine (D, C)
Ranitidine (D, C, H)

GASTROMUCOSAL PROTECTANTS

Sucralfate (D, C, Fer, H, R)

PROSTAGLANDIN E ANALOGS

Misoprostol (D)

PROTON PUMP INHIBITORS

Omeprazole (D, C, H, Sw)
Pantoprazole (D, C, H)

APPETITE STIMULANTS

Cyproheptadine (D, C, H)
Diazepam (D, C, Po, A, B, H, Sw, Sh)
Mirtazapine (D, C)
Oxazepam (C)

GI ANTISPASMODICS-ANTICHOLINERGICS

Aminopentamide (D, C)
Hyoscyamine (D)
N-butylscopolammonium Br (H)
Propantheline (D, C, H)

GI STIMULANTS

Cisapride (D, C, Po, H)
Domperidone (D, C, H)
Metoclopramide (D, C, Po, H)
Neostigmine (D, C, B, H, Sw, Sh)

DIGESTIVE ENZYMES

Pancrelipase (D, C, Po, A)

LAXATIVES

Bisacodyl (D, C)
Docusate (D, C, H)
Psyllium (D, C, H)
Lactulose (D, C, A)
Magnesium Hydroxide (D, C, B, H, Sw, A)
Mineral Oil (D, C, Po, B, H, Sw, Sh, A)
Saline/Hyperosmotic Laxatives (D)

ANTIIDIARRHEALS

Diphenoxylate/Atropine (D, C, Po)
Kaolin/Pectin (D, C, Fer, Po, B, H, Sw, Sh, A)
Paregoric (D, C, H, B)
Loperamide (D, C, Po)
Bismuth Subsalicylate (D, C, B, H, Fer, Sw)

EMETICS

Apomorphine (D, C)
Hydrogen Peroxide % (D, C)
Ipecac Syrup (D, C)
Xylazine (C)

MISCELLANEOUS GI DRUGS

Bismuth Subsalicylate (D, C, Fer, B, H, Sw)
Budesonide (D, C)
Glutamine (D, C)
Dirlotapide (D)
Olsalazine Sodium (D)
Sulfasalazine (D, C, Fer)
Ursodiol (D, C)

Hormones/Endocrine/Reproductive Agents
SEX HORMONES, ESTROGENS

Estradiol (D, C, B, H)
Diethylstilbestrol (DES) (D)

SEX HORMONES, PROGESTINS

Altrenogest (D, H)
 Medroxyprogesterone (D, C, A)
 Megestrol Acetate (D, C)

SEX HORMONES, ANDROGENS

Danazol (D, C)
 Methyltestosterone (D, C)
 Mibolerone (D, C)
 Testosterone (D, C, B)

ANABOLIC STEROIDS

Boldenone (H)
 Stanozolol (D, C, Fer, Po, H, Sh, A, R)
 Nandrolone (D, C)

POSTERIOR PITUITARY HORMONES

Desmopressin (D, C)
 Vasopressin (D, C)

OXYTOXICS

Oxytocin (D, C, Po, B, H, Sw, Sh, A, R)

ADRENAL CORTICAL STEROIDS

Corticotropin-ACTH (D, C, B, H, A)
 Cosyntropin (D, C)
 Mineralocorticoids
 Desoxycorticosterone Piv. (D, C)
 Fludrocortisone (D, C)
 Glucocorticoids
 Betamethasone (D)
 Dexamethasone (D, C, Po, B, H, Sw, L, A, R)
 Fludrocortisone (D, C)
 Flumethasone (D, C, H)
 Hydrocortisone (D, C, B, H)
 Isoflupredone (B, H, SW)
 Methylprednisolone (D, C, H)
 Prednisolone (D, C, Po, Fer, B, H, L, Sw, A, R)
 Prednisone (D, C, Po, Fer, B, H, L, Sw, A, R)
 Triamcinolone (D, C, B, H)

ADRENAL STEROID INHIBITORS

Ketoconazole (D, C, Po, A, R)
 Mitotane (D, Fer)
 Selegiline (D)
 Trilostane (D)

ANTIDIABETIC AGENTS

Acarbose (D, C)
 Insulin (D, C, Fer, B, H, A)
 Chlorpropamide (D, C)
 Glipizide (C)
 Glyburide (C)

GLUCOSE ELEVATING AGENTS

Diazoxide, Oral (D, C, Fer)
 Glucose/Dextrose
 Octreotide Acetate (D, Fer)

THYROID HORMONES

Levothyroxine (D, C, H, A, R)
 Liothyronine (D, C)
 TSH (D, C, H)

ANTITHYROID DRUGS

Carbimazole (C)
 Ipodate Sodium (C)
 Methimazole (D, C)

PROSTAGLANDINS

Cloprostenol (B, H, Sw, Sh)
 Dinoprost (D, C, B, H, Sw, Sh)

MISC. ENDOCRINE/REPRODUCTIVE DRUGS

Aglepristone (D, C)
 Bromocriptine (D, H)
 Chorionic Gonadotropin-HCG (D, C, Fer, Po, B, H, Sh)
 Finasteride (D)
 Follicle Stimulating Hormone (D, C, B, H, Sh, Sw, Po)
 Gonadorelin (D, C, Fer, B, Sh)
 Leuprolide (Fer, A)
 Melatonin (D)
 Mibolerone (D)
 Octreotide Acetate (D, Fer)
 Somatotropin (D)

Anti-infective Drugs**ANTIPARASITICS**

Albendazole (D, C, Po, B, Sw, Sh, A)
 Atovaquone (D)
 Clorsulon (B, Sh, L)
 Dichlorvos (D, C, Po, B, H)
 Diethylcarbamazine (D, C, Fer, B)
 Diminazene (D, C, H, B, Sh)
 Doramectin (B)
 Emodepside + Praziquantel (C)
 Eprinomectin (C)
 Epsiprantel (D, C)
 Fenbendazole (D, C, Po, B, H, Sw, Sh, L, A, R)
 Fenthion (D, B, Sw)
 Furazolidone (D, C, H)
 Imidocarb (D, C, Sh)
 Ivermectin (D, B, Fer, Po, H, Sw, Sh, L, A, R)
 Levamisole (D, C, Po, B, L, Sw, Sh, A)
 Lufenuron (D, C, Po)
 Meglumine Antimoniate (D)
 Melarsomine (D)
 Metronidazole (D, C, Fer, Po, H, A, R)
 Milbemycin Oxime (D, C)
 Morantel (B, Sh)
 Moxidectin (D, H, B)
 Nitenpyram (D)
 Oxfendazole (H, B, Sw, Sh)
 Oxibendazole (H, B, Sw, Sh)
 Piperazine (D, C, Po, H, B, Sw, A)
 Ponazuril (H)
 Praziquantel (D, C, Po, Sh, L, A, R)
 Primaquine (C)
 Pyrantel (D, C, Po, H, Sw, B, L, A, Sh)
 Pyrimethamine (D, C, H)
 Pyrimethamine + Sulfadiazine (H)
 Quinacrine (D, C)
 Ronidazole (C)
 Selamectin (D, C)
 Thiabendazole (D, Po, B, H, Sw, Sh, L, A)
 Tinidazole (D)

ANTIOCCIDIAL AGENTS

Amprolium (D, C, Po, B, Sw, Sh, A)
 Decoquinate (D, B, Sh, L)
 Toltrazuril (D, C, A, H)

ANTIBIOTICS, AMINOCYCLITOLS

Amikacin (D, C, B, Fer, Po, H, A, R)
 Apramycin (D, B)
 Gentamicin (D, C, Fer, Po, H, Sw, A, R)
 Neomycin (D, C, Po, Fer, B, H, Sw, Sh, A, R)
 Spectinomycin (D, C, B, H, Sw, A)
 Tobramycin (D, C, H, A, R)

ANTIBIOTICS, CEPHALOSPORINS

Cefaclor (D, C)
 Cefadroxil (D, C, Fer)
 Cefazolin (D, C, H)
 Cefepime (D, H)
 Cefixime (D)
 Cefoperazone (D, H)
 Cefotaxime (D, C, H, A, R)
 Cefpodoxime Proxetil (D, C)
 Cefotetan Disodium (D, C)
 Cefoxitin (D, C, H)
 Ceftiofur (D, C, A, B, H, R)
 Ceftriaxone (D, C, H)
 Cefuroxime (D)
 Cephalexin (D, C, Po, Fer, H, A)
 Cephalothin Sodium (D, C, B, H, A, R)
 Cephapirin (D, C, B, H)

ANTIBIOTICS, MACROLIDES

Azithromycin (D, C, Po)
 Erythromycins (D, C, Fer, A, B, H, Sw, Sh)
 Tulathromycin (B, Sw)
 Tylosin (D, C, Fer, Po, B, Sw, Sh, A, R)

ANTIBIOTICS, PENICILLINS

Amoxicillin (D, C, Po, Fer, B, H, A, R)
 Amoxicillin/Clavulanate (D, C, H, Fer, A)
 Ampicillin (D, C, B, H, Fer, Sw, Po, A, R)
 Ampicillin/Sulbactam (D, C)
 Carbenicillin (D, C, Po)
 Cloxacillin (D, C, B)
 Dicloxacillin (D, C, Fer, B)
 Oxacillin (D, C, H)
 Penicillin G (D, C, Fer, Po, B, H, Sw, A)
 Penicillin V (D, C, H)
 Piperacillin (D, C, H, A, R)
 Piperacillin/Tazobactam (D, C, A)
 Ticarcillin/Clavulanate (D, C, H)

ANTIBIOTICS, TETRACYCLINES

Chlortetracycline (D, C, Po, A, B, Sw)
 Doxycycline (D, C, Po, H, A, R)
 Minocycline HCl (D, C)
 Oxytetracycline (D, C, B, Po, Sw, Sh, H, A, R)
 Tetracycline (D, C, Fer, Po, B, Sh, H, Sw, A)

ANTIBIOTICS, LINCOSAMIDES

Clindamycin (D, C, Fer)
 Lincomycin (D, C, Fer, Sw)
 Pirlimycin (B)
 Tilmicosin (B, Po)

ANTIBIOTICS, QUINOLONES

Difloxacin (D)
 Enrofloxacin (D, C, H, B, Fer, Po, R, A)
 Ciprofloxacin (D, C, Fer, Po, A)
 Danofloxacin (B)
 Ibafoxacin (D, C)
 Marbofloxacin (D)
 Orbifloxacin (D, C)

ANTIBIOTICS, SULFONAMIDES

Sulfachlorpyridazine (B, Sw, A)
Sulfadiazine/Trimethoprim (D, C, Fer, Po, B, H, Sw, A, R)
Sulfamethoxazole/Trimethoprim (D, C, Fer, Po, B, H, Sw, A, R)
Sulfadimethoxine/Ormetoprim (D)
Sulfadimethoxine (D, C, Fer, Po, B, H)

MISCELLANEOUS ANTIBIOTICS, ANTIBACTERIALS

Aztreonam (Fish)
Chloramphenicol (D, C, Po, Fer, H, A, R)
Ethambutol (D, C, A)
Ertapenem (D, C)
Florfenicol (D, C, B)
Imipenem-Cilastatin (D, C, H)
Isoniazid (D)
Metronidazole (D, C, Po, Fer, H, A, R)
Methenamine (D, C)
Nitrofurantoin (D, C, H)
Novobiocin (D, B)
Rifampin (D, C, H)
Sodium Iodide (D, C, B, Sh, H)
Tiamulin (Sw)
Tinidazole (D, C, H)

ANTIFUNGAL AGENTS

Amphotericin B (D, C, H, Po, L, A, R)
Caspofungin (D, C)
Fluconazole (D, C, Po, A)
Flucytosine (D, C, A)
Griseofulvin (D, C, Po, B, H, Sw, A)
Itraconazole (D, C, Po, A, H)
Ketoconazole (D, C, Po, A, R)
Nystatin (D, C, H, A, R)
Terbinafine HCl (D, C, A)
Voriconazole (D)

ANTIVIRAL AGENTS

Acyclovir (A, C)
Amantadine (D, C, H)
Famciclovir (C)
Interferon Alfa (D, C)
Interferon Omega (D, C)
Oseltamivir (D, H)
Zidovudine (AZT) (C)

Blood Modifying Agents
ANTICOAGULANTS/ANTITHROMBOTICS

Aspirin (D, C)
Clopidogrel (C)
Heparin (D, C, H)
Streptokinase (D)
Warfarin (D, C, H)

ERYTHROPOIETIC AGENTS

Cyanocobalamin (D, C, H, SW)
Darbepoetin (D, C)
Epoetin Alfa (Erythropoietin) (D, C, Fer, Po)

Ferrous Sulfate (D, C, B, H, Sw, Sh)

Folic Acid (D, C, H)

Iron Dextran (D, C, Fer, Sw, A)

MISC. BLOOD MODIFYING AGENTS

Aminocaproic Acid (D)
Filgrastim (D, C)
Gemfibrozil (D, C)

Hemoglobin Glutamer (D)
Pentoxifylline (D, H)
Phytonadione (D, C, Po, H, B, Sw, Sh, A)
Protamine Sulfate (D, C, B)

Fluid & Electrolyte Modifiers

Aluminum Antacids (D, C)
Calcium Acetate (D, C)
Calcitonin (D, R)
Calcitriol (D, C)
Calcium Salts (D, C, B, H, Sh, Sw, A, R)
Dextran (D)
Dihydrotachysterol (D, C)
Ergocalciferol (D, C)
Etidronate (D, C)
Glycerine, Oral (D, C)
Hetastarch (D, C)
Magnesium Sulfate Inj. (D, C, B, H, Sh, Sw)
Mannitol (D, C, B, Sw, Sh, H)
Phosphate (D, C)
Potassium (D, C, B, Sh)
Sevelamer HCl
Sodium Polystyrene Sulfonate (D)

Antineoplastics
ANTINEOPLASTICS, ALKYLATING AGENTS

Busulfan (D, C)
Carboplatin (D, C)
Chlorambucil (D, C, H)
Cisplatin (D)
Cyclophosphamide (D, C, Sh)
Dacarbazine (D)
Lomustine (D)
Mechlorethamine (D)
Melphalan (D, C)
Thiotepa (D)

ANTINEOPLASTICS, ANTIMETABOLITES

Cytarabine (D, C)
Fluorouracil (-FU) (D, C)
Mercaptopurine (D)
Methotrexate (D, C)
Thioguanine (D, C)

ANTINEOPLASTICS, ANTIBIOTICS

Bleomycin (D, C)
Dactinomycin (D)
Doxorubicin (D, C, Fer)
Streptozocin (D)

ANTINEOPLASTICS, MITOTIC INHIBITORS

Vinblastine (D, C)
Vincristine (D, C)

ANTINEOPLASTICS, MISCELLANEOUS

Asparaginase (D, C)
Hydroxyurea (D, C)
Mitoxantrone (D, C)
Piroxicam (D, C, Po)

Immunomodulators
IMMUNOSUPPRESSIVE DRUGS

Azathioprine (D, C)
Cyclophosphamide (D, C, Sh)
Cyclosporine (D, C)
Dexamethasone (D, C, Po, B, H, Sw, L, A, R)
Flumethasone (D, C, H)

Leflunomide (D, C)
Mercaptopurine (D)
Methotrexate (D, C)
Mycophenolate (D)
Methylprednisolone (D, C, H)
Prednisolone (D, C, Po, Fer, B, H, L, Sw, A, R)
Prednisone (D, C, Po, Fer, B, H, L, Sw, A, R)
Triamcinolone (D, C, B, H)

GOLD COMPOUNDS

Aurothioglucose (D, C, H)
Auranofin (D)
Gold Sodium Thiomalate (D, C)

IMMUNOSTIMULANTS

Acemannan (D, C)
Mycobacterial Cell Wall Fraction Immunomodulator (D, H)
Parapox Ovis Virus Immunomodulator (H)
Staphylococcal Phage Lysate (D)

Antidotes

Acetylcysteine (D, C)
Ammonium Molybdate (Sh)
Ammonium Tetrathiomolybdate (Sh)
Antivenin Black Widow Spider (D, C)
Antivenin Crotalidae (D, C, H)
Antivenin Coral Snake (D, H)
Atipamezole (D, Po, A, R)
Charcoal, Activated (D, C, H, B, Sh)
Deferoxamine (D, C)
Dimercaprol (D, C, H, B)
Edetate Calcium Disodium (D, C, Po, H, A, B, Sw)
Ethanol (D, C)
Fomepizole (D)
Leucovorin Calcium (D, C, H)
Methylene Blue (D, C, B, Sh)
Naloxone (D, C, Po, H)
Penicillamine (D, C)
Physostigmine (D, H)
Phytonadione (D, C, Po, B, H, Sw, Sh, A)
Pralidoxime (D, C, B, H)
Protamine Sulfate (DF, C, B)
Pyridoxine (D, C)
Sodium Polystyrene Sulfonate (D)
Sodium Sulfate (B, Sh, Sw)
Sodium Thiosulfate (H, B, Sh)
Succimer (D, A)
Thiamine (D, C, B, H, Sw, Sh)
Trientine HCl (D)
Zinc Acetate/Sulfate (D, C)

Bone/Joint Agents

Alendronate Sodium (D, C)
Allopurinol (D, C, A)
Hyaluronate (D, H)
Etidronate (D, C)
Pentosan (D, C, H)
Polysulfated Glycosaminoglycan (H, D, C, Po)
Tiludronate Disodium (H)

Dermatologic Agents (Systemic)

Fatty Acids, Essential (D, C)
Acitretin (D, C)
Isotretinoin (D, C)
Pentoxifylline (D, H)

Vitamins and Minerals/Nutrients

Ascorbic Acid (C, Po, H, B)
Carnitine (D, C)
Cyanocobalamin (D, C, H, SW)
Fatty Acids, Essential (D, C)

Folic Acid (D, C, H)
Medium Chain Triglycerides (D)
Niacinamide (D)
Pyridoxine (D, C)
Thiamine (D, C, B, H, Sw, Sh)
Vitamin E/Selenium (D, C, B, Sw, Sh, H)
Zinc Acetate/Sulfate (D, C)

Cholinergic Muscle Stimulants

Edrophonium Chloride (D, C)
Pyridostigmine (D, C)

Systemic Acidifiers

Acetazolamide (D, C, B, Sh, Sw)
Acetic Acid (B, Sh, H)

Systemic Alkalinizers

Sodium Bicarbonate (D, C, H, B, Sh, A)

Unclassified

Aminocaproic Acid (D)
Colchicine (D)
